WELLCOME
HISTORICAL
MEDICAL
LIBRARY

TO

WILLIAM SAUNDERS, M.D. F.R.S.

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS;

AND OF

THE ANTIQUARIAN AND OTHER SOCIETIES;

THIS WORK

IS DEDICATED,

AS

A MARK OF RESPECT AND ESTEEM,

BY

HIS SINCERE FRIEND,

THE AUTHOR.

PREFACE.

In offering another edition of the Medical Dictionary to the public, the Editor, desirous of rendering it as generally useful as possible, has made considerable additions and alterations by the insertion of the treatment of diseases, the Biography of eminent Medical Men, and the pronunciation of the several terms.

Due attention has been given to the anatomical description of the various parts of the human body, and the explanation of their functions.

The most approved nosological arrangement of the diseases is selected, and their genera and species fully enumerated.

Particular attention has been given to the Materia Medica which is arranged under the Linnæan genera; the preparations which enter the last edition of the London Pharmacopœia are minutely mentioned, and the later discoveries in chemistry inserted.

The derivation of the terms, however fanciful, is still retained, and the declension of the words which are in common use is given.

The Compiler has generally to acknowledge his obligations to Abernethy, Accum, Aiken, Albinus, Bell, Brande, Bergius, Blanchard, Burns, Burserius, Callisen, Castelli, Chaptal, Cooper, Cruickshank, Cullen, Davy, Denman, Duncan, Edinburgh Dispensary, Editors of Rees' Cyclopœdia, and Motherley's Dictionary, Fourcroy, Haller, Hunter, Innis, Latta, Lavoisier, Lewis, Linnæus, Meyer, Murray, Nicholson, Pott, Richerard, Richter, Saunders, Sauvage, Scarpa, Smith, Soemmering, Swediaur, Symonds, Thomas, Thompson, Turton, Vaughan, Vossius, Willan, Willson, Woodville.

It was the Editor's original intention to have given to each writer the merit of the particular description selected from his work, but having occasion to consult, frequently to abridge, and sometimes to alter various passages in works connected with the subject; and finding it difficult, and in many instances, impossible, to discover the original writer of several articles; and, convinced at the same time it would be attended with no particular advantage, he prefers making a general acknowledgement to particularising the labours of each individual. If he has been so fortunate as to have compressed within the narrow limits of the present publication much general and useful information, his object will be fully answered.

21. Savile-Row,
June 1820.

A NEW

MEDICAL DICTIONARY.

A. AA. ANA. (From *ανα*, which signifies of each.) A term in pharmacy, used after the mention of two or more ingredients, when it implies, that the quantity mentioned of each ingredient should be taken; e. g. ℞. *Potassæ nitratis: Sacchari albi* āā ʒj. *i. e.* Take nitrate of potash and white sugar, of each one drachm.

A′bam. A term used by some antient chymists for lead.

AA′RON. A physician of Alexandria, author of thirty books in the Syriac tongue, containing the whole practice of physic, chiefly collected from the Greek writings, and supposed to have been written before 620. He first mentioned, and clearly described, the small-pox and measles, which were probably brought thither by the Arabians. He directed the vein under the tongue to be opened in jaundice, and noticed the white colour of the fæces in that disease. His works are lost, except some fragments, preserved by Rhazes.

Aba′ctus. *Abigeatus.* Among the antient physicians, this term was used for a miscarriage, procured by art, or force of medicines, in contradistinction to *abortus*, which meant a natural miscarriage. The moderns know no such distinctions.

A′bacus. (From a Hebrew word, signifying dust.) A table for preparations, so called from the usage of mathematicians of drawing their figures upon tables sprinkled with dust.

Abai′sir. *Abasis. Spodium. Arabum.* Ivory black; and also calcareous powder.

Abaliena′tio. A decay of the body, or mind.

Abaliena′tus. Corrupted. A part so destroyed as to require immediate extirpation; also the fault or total destruction of the senses, whether external or internal, by disease.

A′banet. (Hebrew, the girdle worn by the Jewish priests.) A girdle-like bandage.

Aba′nga. *Ady.* The palm of the Island of St. Thomas, from which Thernal's restorative is prepared.

Abapti′sta. (From *α*, priv. and *βαπτω*, to plunge.) *Abaptiston.* The shoulders of the old trepan. This term is employed by Galen, Fabricius ab Aquapendente, Scultetus, and others, to denote the conical saw with a circular edge, (otherwise called modiolus, or terebra,) which was formerly used by surgeons to perforate the cranium.

Abapti′ston. See *Abaptista.*

Abarnahas. *Ovum ruffum.* A chemical term formerly used in the transmutation of metals, signifying *luna plena, magnes,* or *magnesia.*

Aba′rtamen. Lead.

Abarticulation. (From *ab*, and *articulus*, a joint.) That species of articulation which has evident motion. See *Diarthrosis.*

A′bas. (An Arabian word.) The scald-head; also epilepsy.

Aba′sis. See *Abaisir.*

Abbreviation. The principal uses of medicinal abbreviations are in prescriptions; in which they are certain marks, or half words, used by physicians for dispatch and conveniency when they prescribe, thus: — ℞ readily supplies the place of *recipe* — *h. s.* that of *hora somni* — *n. m.* that of *nux moschata* — *elect.* that of *electarium*, &c.; and in general all the names of compound medicines, with the several ingredients, are frequently wrote only up to their first or second syllable, or sometimes to their third or fourth, to make them clear and expressive. Thus *Croc. Anglic.* stands for *Crocus Anglicanus* — *Conf. Aromat.* for *Confectio Aromatica*, &c. A point being always placed at the end of such syllable, shews the word to be incomplete.

ABDO′MEN. (*Abdomen, inis. n.* from *abdo*, to hide, because it hides the viscera. It is also derived from *abdere* to hide, and *omentum*, the caul; by others *omen* is said to be only a termination, as from *lego*, *legumen*, so from *abdo*, *abdomen.*) The belly.

The abdomen is the largest cavity in the body, bounded superiorly by the diaphragm, by which it is separated from the chest; inferiorly by the bones of the pubes and ischium; on each side by various muscles, the short ribs and ossa ilii; anteriorly by the abdominal muscles, and posteriorly by the vertebræ of the loins, the os sacrum and os coccygis. Internally it is invested by a smooth membrane, called peritoneum, and externally by muscles and common integuments.

In the cavity of the abdomen are contained,

1. *Anteriorly* and *laterally*.

1. The epiploon. 2. The stomach. 3. The large and small intestines. 4. The mesentery. 5. The lacteal vessels. 6. The pancreas. 7. The spleen. 8. The liver and gall-bladder.

2. *Posteriorly, without the peritoneum*, are,

1. The kidneys. 2. The supra-renal glands. 3. The ureters. 4. The receptaculum chyli. 5. The descending aorta. 6. The ascending vena cava.

3. *Inferiorly in the pelvis*, and *without the peritoneum*,

In men, 1. The urinary bladder. 2. The spermatic vessels. 3. The intestinum rectum.

In women, besides the urinary bladder and intestinum rectum, there are,

1. The uterus. 2. The four ligaments of the uterus. 3. The two ovaria. 4. The two Fallopian tubes. 5. The vagina.

The fore part of this cavity, as has been mentioned, is covered with muscles and common integuments, in the middle of which is the navel. It is this part of the body which is properly called abdomen; it is distinguished, by anatomists, into regions.

The posterior part of the abdomen is called the loins, and the sides the *Epicolic regions*.

Abdominal Hernia. See *Hernia abdominalis*.

Abdominal muscles. See *Muscles*.

Abdominal ring. See *Annulus Abdominis*.

Abdominal regions. See *Body*.

Abdu′cens. See *Abductor*.

Abdu′cens Labio′rum. See *Levator anguli oris*.

Abducent nerves. See *Nervi abducentes*.

Abducent muscles. See *Abductor*.

ABDU′CTOR. (From *abduco*, to draw away.) *Abducens*. A muscle, the office of which is to pull back or draw the member to which it is affixed from some other. The antagonist is called *adductor*.

Abductor auricularis. See *Posterior auris*.

Abductor auris. See *Posterior auris*.

Abductor brevis alter. See *Abductor pollicis manûs*.

ABDU′CTOR I′NDICIS MA′NUS. *Abductor* of Douglas. *Semi-interosseus indicis* of Winslow. *Abductor indicis* of Cowper.

An internal interosseous muscle of the fore-finger, situated on the hand. It arises from the superior part of the metacarpal bone, and the os trapezium, on its inside, by a fleshy beginning, runs towards the metacarpal bone of the fore-finger, adheres to it, and is connected by a broad tendon to the superior part of the first phalanx of the fore-finger. Sometimes it arises by a double tendon. Its use is to draw the fore-finger from the rest, towards the thumb, and to bend it somewhat towards the palm.

ABDU′CTOR I′NDICIS PE′DIS. An internal interosseous muscle of the fore-toe, which arises tendinous and fleshy, by two origins, from the root of the inside of the metatarsal bone of the fore-toe, from the outside of the root of the metatarsal bone of the great-toe, and from the os cuneiforme internum, and is inserted tendinous into the inside of the root of the first joint of the fore-toe. Its use is to pull the fore-toe inwards, from the rest of the small toes.

Abductor longus pollicis manûs. See *Extensor ossis metacarpi pollicis manûs*.

ABDU′CTOR ME′DII DI′GITI PE′DIS. An interosseous muscle of the foot, which arises tendinous and fleshy, from the inside of the root of the metatarsal bone of the middle toe internally, and is inserted tendinous into the inside of the root of the first joint of the middle toe. Its use is to pull the middle toe inwards.

ABDU′CTOR MI′NIMI DI′GITI MA′NUS. *Carpo-phalangien du petit doigt* of Dumas. *Extensor tertii internodii minimi digiti* of Douglas. *Hypothenar minor* of Winslow.

A muscle of the little finger, situated on the hand. It arises fleshy from the pisiform bone, and from that part of the *ligamentum carpi annulare* next it, and is inserted, tendinous, into the inner side of the upper end of the first bone of the little finger. Its use is to draw the little finger from the rest.

ABDU′CTOR MI′NIMI DI′GITI PE′DIS. *Calcaneo-phalangien du petit doigt* of Dumas. *Adductor* of Douglas. *Parathenar major* of Winslow, by whom this muscle is divided into two, *Parathenar major* and *metatarseus*. *Adductor minimi digiti* of Cowper.

A muscle of the little toe, which arises tendinous and fleshy, from the semicircular edge of a cavity on the inferior part of the protuberance of the os calcis, and from the rest of the metatarsal bone of the little toe, and is inserted into the root of the first joint of the little toe externally. Its use is to bend the little toe, and its metatarsal bone downwards, and to draw the little toe from the rest.

Abdu′ctor o′culi. See *Rectus externus oculi*.

ABDU′CTOR PO′LLICIS MA′NUS. *Scaphosus-phalangien du pouce* of Dumas. *Adductor pollicis manûs*, and *Adductor brevis alter* of Albinus. *Adductor thenar Riolani* of Douglas, (the *adductor brevis alter* of Albinus is the inner portion of this muscle.) *Adductor pollicis* of Cowper.

A muscle of the thumb, situated on the hand. It arises by a broad tendinous and fleshy beginning, from the *ligamentum carpi annulare*, and from the *os trapezium*, and is inserted tendinous into the outer side of the root of the first bone of the thumb. Its use is to draw the thumb from the fingers.

ABDU′CTOR POLLI′CIS PE′DIS. *Calcaneo-phalangien du pouce* of Dumas. *Abductor* of Douglas. *Thenar* of Winslow. *Abductor pollicis* of Cowper.

A muscle of the great toe, situated on the foot. It arises fleshy, from the inside of the root of the protuberance of the os calcis, where it forms the heel, and tendinous from the same bone, where it joins the os naviculare; and is inserted tendinous into the internal sesamoid bone and root of the first joint of the great toe. Its use is to pull the great toe from the rest.

ABDU′CTOR TE′RTII DI′GITI PE′DIS. An interosseous muscle of the foot, that arises tendinous and fleshy from the inside and the inferior part of the root of the metatarsal bone of the third toe; and is inserted tendinous into the inside of the root of the first joint of the third toe. Its use is to pull the third toe inwards.

Abebæ′os. (From α, neg. and βεβαιος, firm.) *Abebæus.* Weak, infirm, unsteady. A term made use of by Hippocrates de Signis.

Abebæ′us. See *Abebæos.*

Abelmo′schus. (Arabian.) The seeds of the *Hibiscus Abelmoschus.* See *Hibiscus.*

Abelmosch. See *Hibiscus.*

Abelmusk. See *Hibiscus.*

Aberra′tio (From *ab* and *erro*, to wander from.) *Lusus naturæ.* Dislocation.

Abe′ssi. (Arabian.) Filth. The alvine excrements.

A′besum. Quick lime.

Abevacua′tio. (From *ab*, dim. and *evacuo*, to pour out.) A partial or incomplete evacuation of the peccant humours, either naturally or by art.

A′BIES. (*Abies, etis*, fem. from *abeo*, to proceed, because it rises to a great height; or from απιος, a wild pear, the fruit of which its cones something resemble.) The fir. An evergreen tree. Linnæus includes the abies in the genus Pinus. See *Pinus.*

A′bies Canade′nsis. See *Pinus Balsamea.*

Abigea′tus See *Abactus.*

Abio′tos. (From α, neg. and βιοω, to live.) A name given to hemlock, from its deadly qualities. See *Conium.*

Ablacta′tio. (From *ab*, from, and *lac* milk.) *Ablactation.* The weaning of a child from the breast.

Abla′tio. (From *aufero*, to take away.) The taking away from the body whatever is useless or hurtful; it comprehends all kinds of evacuations. Sometimes it signifies the subtraction of a part of the diet, with a medical view; and sometimes it expresses the interval betwixt two fits of a fever, or the time of remission.

Chemical *ablation* is the removal of any thing that is either finished or else no longer necessary in a process.

Ablue′ntia. (*Abluentia*, sc. *medicamenta*, from *abluo*, to wash away.) *Abstergents. Abluents.* Medicines which were formerly supposed to purify or cleanse the blood.

ABLUTION. (From *abluo*, to wash off.) A washing or cleansing either of the body or the intestines.

In chemistry it signifies the purifying of a body, by repeated affusions of a proper liquor.

Abo′it. An obsolete term of Arabic extraction, for white lead.

Aboli′tio. (From *aboleo*, to destroy.) The separation or destruction of diseased parts.

ABORTION. (*Abortio*, from *aborior*, to be steril.) *Aborsus. Amblosis. Diaphthora. Ectrosis. Exambloma. Examblosis. Apopallesis. Apopalsis. Apophthora.*

Miscarriage, or the expulsion of the fœtus from the uterus, before the seventh month, after which it is called premature labour. It most commonly occurs between the eighth and eleventh weeks of pregnancy, but may happen at a later period. In early gestation, the ovum sometimes comes off entire; sometimes the fœtus is first expelled, and the placenta afterwards. It is preceded by flooding, pains in the back, loins, and lower part of the abdomen, evacuation of the water, shiverings, palpitation of the heart, nausea, anxiety, syncope, subsiding of the breasts and belly, pain in the inside of the thighs, opening and moisture of the os tincæ. The principal causes of miscarriage are blows or falls; great exertion or fatigue; sudden frights and other violent emotions of the mind; a diet too sparing or too nutritious; the abuse of spirituous liquors; other diseases, particularly fevers, and hæmorrhages; likewise excessive bleeding, profuse diarrhœa or colic, particularly from accumulated fæces; immoderate venery, &c. The spontaneous vomiting, so common in pregnancy, rarely occasions this accident: but when induced and kept up by drastic medicines, it may be very likely to have that effect. Abortion often happens without any obvious cause, from some defect in the uterus, or in the fœtus itself, which we cannot satisfactorily explain. Hence it will take place repeatedly in the same female at a particular period of pregnancy; perhaps in some measure from the influence of habit.

The treatment of abortion must vary considerably according to the constitution of the patient, and the causes giving rise to it. If the incipient symptoms should appear in a female of a plethoric habit, it may be proper to take a moderate quantity of blood from the arm, then clear the bowels by some mild cathartic, as the sulphas magnesiæ in the infusum rosæ, afterwards exhibiting small doses of nitrate of potash, directing the patient to remain quiet, in a recumbent position, kept as cool as possible, with a low diet, and the antiphlogistic regimen in other respects. Should there be much flooding, cloths wetted with cold water ought to be applied to the region of the uterus, or even introduced into the vagina, to obstruct the escape of the blood mechanically. Where violent forcing pains attend, opium should be given by the mouth, or in the form of glyster, after premising proper evacuations. Should these means not avail to check the discharge or the forcing pains, and particularly if the water be evacuated, there can be no expectation of preventing the miscarriage; and where there is reason for believing the fœtus dead, from the breasts having previously subsided, the morning sickness gone off, the motion stopped, &c. it will be proper rather to encourage it by manual assistance.

If on the other hand females of a delicate and irritable habit, rather deficient in blood, be subject to abortion, or where this accident is threatened by profuse evacuations and other debilitating causes, it may be more probably prevented by a diet nutritious, yet easy of digestion, with tonic medicines, and the use of the cold bath, attending at the same time to the state of the bowels, giving opium if pain attend, and carefully avoiding the several exciting causes.

Abortives. (*Abortiva,* sc. *medicamenta;* from *aborior,* to be steril.) *Amblotica. Ecbolica.*

Medicines capable of occasioning an abortion, or miscarriage, in pregnant women. It is now generally believed, that the medicines which produce a miscarriage, effect it by their violent action on the system, and not by any specific action on the womb.

Abra′sa. (From *abrado,* to shave off.) Ulcers attended with abrasion of part of the substance.

ABRASION. (*Abrasio,* from *abrado* to tear off.) This word is generally employed to signify the destruction of the natural mucus of any part, as the stomach, intestines, urinary bladder, &c. It is also applied to any part slightly torn away by attrition, as the skin, &c.

A′brathan. Corrupted from abrotanum, southernwood. See *Artemisia.*

A′brette. See *Hibiscus.*

A′bric. An obsolete Arabic term for sulphur.

Abro′ma. (From *α* neg. and *ϐϱωμα,* food; i. e. not fit to be eaten.) A tree of New South Wales, which yields a gum.

ABRO′TANUM. (*Αϐϱοτανον,* from *α,* neg. and *ϐϱοτος,* mortal; because it never decays: or from *αϐϱος,* soft, and *τονος,* extension; from the delicacy of its texture.) Common southernwood. See *Artemisia.*

Abro′tanum mas. See *Artemisia.*

Abrotoni′tes. (From *abrotanum.*) A wine mentioned by Dioscorides, impregnated with *abrotanum,* or southernwood, in the proportion of about one hundred ounces of the dried leaves, to about seven gallons of must.

Abscede′ntia. (From *abscedo,* to separate.) Decayed parts of the body, which, in a morbid state, are separated from the sound.

ABSCESS. (From *abscedo,* to depart; because parts, which were before contiguous, become separated, or depart from each other.) *Abscessio. Abscessus. Imposthuma.*

A collection of pus in the cellular membrane, or in the viscera, or in bones, preceded by inflammation.

Abscesses have been variously denominated according to their seat: as empyema, when in the cavity of the pleura; vomica, in the lungs; panaris, in any of the fingers; hypopyon, in the anterior chamber of the eye; arthropuosis, in a joint; also lumbar abscess, &c.

The formation of an abscess is the result of inflammation terminating in suppuration. This is known by a throbbing pain, which lessens by degrees, as well as the heat, tension, and redness of the inflamed part; and if the pus be near the surface, a cream-like whiteness is soon perceived, with a prominence about the middle, or at the inferior part, then a fluctuation may be felt, which becomes gradually more distinct, till at length the matter makes its way externally. When suppuration occurs to a considerable extent, or in a part of importance to life, there are usually rigors, or sudden attacks of chilliness, followed by flushes of heat; and unless the matter be soon discharged, and the abscess healed, hectic fever generally comes on. When abscesses form in the cellular membrane in persons of a tolerably good constitution, they are usually circumscribed, in consequence of coagulable lymph having been previously effused, and obliterated the communication with the adjoining cells; but in those of a weakly, and especially a scrophulous constitution, from this not occurring, the pus is very apt to diffuse itself, like the water in anasarca. Another circumstance, which may prevent its readily reaching the surface, is its collecting under an aponeurosis, or other part of dense structure, when the process of ulceration will rather extend in another direction. Thus pus accumulating in the loins, may descend to the lower part of the thigh.

When suppuration occurs, if the inflammation have not yet subsided, it may be necessary to employ means calculated to moderate this, in order to limit the extent of the abscess: but evacuations must not be carried too far, or there will not be power in the system to heal it afterwards. If the disease be near the surface, fomentations or warm emollient poultices should be employed, to take off the tension of the skin, and promote the process of ulceration in that direction. As soon as fluctuation is obvious, it will be generally proper to make an opening, lest contiguous parts of importance should be injured; and often at an earlier period, where the matter is prevented from reaching the surface by a fascia, &c. but it is sometimes advisable to wait awhile, especially in large spontaneous abscesses, where the constitution is much debilitated, till by the use of a nutritious diet, with bark and other tonic means, this can be somewhat improved. There are different modes of opening abscesses. 1. By incision or puncture; this is generally the best, as being least painful, and most expeditious, and the extent of the aperture can be better regulated. 2. By caustic; this may be sometimes preferable, when suppuration goes on very slowly in glandular parts, (especially in scrophulous and venereal cases) lessening the subjacent tumour, giving free vent to the matter, and exciting more healthy action in the sore; but it sometimes causes much deformity, it can hardly reach deepseated abscesses, and the delay may be often dangerous. 3. By seton; this is sometimes advantageous in superficial abscesses, (where suppuration is likely to continue,) about the neck and face, leaving generally but a small scar; likewise when near joints, or other important parts liable to be injured by the scalpel or seton. See *Lumbar Abscess*, and *Ulcer*.

Abscission. (*Abscissio*; from *ab*, and *scindo*, to cut.) *Apocope.* The taking away some morbid, or other part, by an edged instrument. The abscission of the prepuce makes what we call circumcision. Abscission is sometimes used by medical writers to denote the sudden termination of a disease in death, before it arrives at its decline. Celsus frequently uses the term *abscissa vox* to express a loss of voice.

ABSI'NTHIUM. (Αψινθιον, from *α*, neg. and *ψινθος*, pleasant: so called from the disagreeableness of the taste.) A genus of plants which is ranked under *Artemisia* in the Linnæan system. Class, *Syngenesia*. Order, *Polygamia superflua*. Wormwood. See *Artemisia*.

Absi'nthium commune. See *Artemisia Absinthium*.

Absi'nthium maritimum. See *Artemisia Maritima*.

Absi'nthium po'nticum. See *Artemisia Pontica*.

Absi'nthium vulgare. See *Artemisia Absinthium*.

Absorbing vessels. See *Absorbents*.

ABSORBENTS. *Absorbentia.*

1. Small, delicate, transparent vessels, which take up any fluid from the surface of the body, or of any cavity in it, and carry it to be mixed with the blood. They are denominated according to the liquids which they convey, lacteals and lymphatics. See *Lacteals* and *Lymphatics*.

2. Medicines are so termed, which have no acrimony in themselves, and destroy acidities in the stomach and bowels; such are magnesia, prepared chalk, oyster-shells, crab's claws, &c.

ABSORPTION. (From *absorbeo*, to suck up.) A function in an animated body, arranged by physiologists under the head of natural actions. It signifies the taking up of substances applied to the mouths of absorbing vessels: thus the nutritious part of the food is absorbed from the intestinal canal by the lacteals: thus mercury is taken into the system by the lymphatics of the skin, &c. The principle by which this function takes place, is a power inherent in the mouths of the absorbents, a *vis insita*, dependent on the degree of irritability of their internal membrane by which they contract and propel their contents forwards.

Abste'ntio. Cælius Aurelianus uses this word, to express a suppression, or retention. Thus, *abstentio stercorum*, a retention of the excrements, which he mentions as a symptom very frequent in a satyriasis. In a sense somewhat different, he uses the word *abstenta*, applying it to the pleura, where he seems to mean, that the humour of the inflamed pleura is prevented, by the adjacent bones, from extending itself.

ABSTERGENTS. (*Abstergentia* scilicèt *medicamenta*; from *abstergo*, to cleanse away.) Lotions, or any application that cleanses or clears away foulness. The term is seldom employed by modern writers.

Abstraction. (From *abstraho*, to draw away.) A term employed by chymists in the process of humid distillation, to signify that the fluid body is again drawn off from the solid, which it had dissolved.

Abstracti'tius. (From *abstraho*, to draw away.) Native spirit, not produced by fermentation.

A'bsus. An obsolete term for the Egyptian lotus.

Abvacua'tio. (From *abvacuo*, to empty.) Local or morbid discharge. A large evacuation of any fluid, as of blood from a plethoric person.

Aca'ca. (From *α* neg. and *κακος*, bad.) Diseases which are rather troublesome than dangerous.

ACA'CIA. (Ακακια, from *ακαζω*, to sharpen.) The name of a genus of plants in the Linnæan system. The Egyptian thorn.

ACA'CIA CA'TECHU. This plant affords a drug, formerly supposed to be an earthy substance brought from Japan, and therefore called *Terra Japonica*, Japan earth; afterwards it appeared to be an extract, prepared in India, it was supposed till lately, from the juice of the *Mimosa catechu* of Linnæus: — *spinis stipularibus, foliis bipinnatis multijugis, glandulis partialium, singulis, spicis axillaribus geminis seu ternis pedunculatis*; by boiling the wood, and evaporating the decoction by the heat of the sun. But the shrub is now ascertained to be an acacia, and is termed *Acacia catechu*. In its purest state, it is a dry pulverable substance, outwardly of a reddish colour, internally of a shining dark brown, tinged with a reddish hue; in the mouth it discovers considerable adstringency, succeeded by a sweetish mucilaginous taste. It may be advantageously employed for most purposes where an adstringent is indicated; and is particularly useful in alvine fluxes, where astringents are required. Besides this, it is employed also in uterine profluvia, in laxity and debility of the viscera in general; and it is an excellent topical adstringent, when suffered to dissolve leisurely in the mouth, for laxities and ulcerations of the gums, aphthous ulcers in the mouth. and similar affections. This extract is the basis of several formulæ in our pharmacopœias, particularly of a tincture: but one of the best forms under which it can be exhibited, is that of a simple infusion in warm water with a proportion of cinnamon, for by this means it is at once freed of its impurities and improved by the addition of the aromatic. Fourcroy says that catechu is prepared from the seeds of a kind of palm, called areca.

Aca′cia Germa′nica. German acacia, or the German black-thorn or sloe-tree. *Acacia nostras. Succus pruni sylvestris.* The inspissated juice of the *prunus spinosa*, or *prunus sylvestris spinosa* of Linnæus; now fallen into disuse.

Aca′cia Indica. See *Tamarindus Indica.*

Aca′cia no′stras. See *Acacia Germanica.*

ACA′CIA VE′RA. True Acacia.

1. This is the name given by Wildenow to the *Mimosa Nilotica* of Linnæus; *spinis stipularibus patentibus, foliis bipinnatis: partialibus extimis glandula interstinctis, spicis globosis pedunculatis,* the Egyptian Thorn. This tree yields the true Acacia Gum, or Gum Arabic, called also *Gummi acanthinum. Gummi thebaicum. Gummi scorpionis. Gumlamac. Gummi senega,* or *senica.*

Cairo and Alexandria were the principal marts for gum-arabic, till the Dutch introduced the gum from Senegal into Europe, about the beginning of the seventeenth century, and this source now supplies the greater part of the vast consumption of this article.

The tree which yields the Senegal gum, grows abundantly on the sands, along the whole of the Barbary coast, and particularly about the river Senegal. There are several species, some of which yield a red astringent juice, but others afford only a pure, nearly colourless, insipid gum, which is the great article of commerce. These trees are from eighteen to twenty feet high, with thorny branches. The gum makes its appearance about the middle of November, when the soil has been thoroughly saturated with periodical rains. The gummy juice is seen to ooze through the trunk and branches, and, in about a fortnight, it hardens into roundish drops, of a yellowish white, which are beautifully brilliant where they are broken off, and entirely so when held in the mouth for a short time, to dissolve the outer surface. No clefts are made, nor any artificial means used by the Moors, to solicit the flow of the gum. The lumps of gum-senegal are usually about the size of partridge eggs, and the harvest continues about six weeks. This gum is a very wholesome and nutritious food; thousands of the Moors supporting themselves entirely upon it during the time of harvest. About six ounces is sufficient to support a man for a day; and it is besides, mixed with milk, animal broths, and other victuals.

The gum-arabic, or that which comes directly from Egypt and the Levant, only differs from the gum-senegal in being of a lighter colour, and in smaller lumps; and it is also somewhat more brittle. In all other respects, the two resemble each other perfectly.

Gum-arabic is neither soluble in spirit nor in oil; but, in twice its quantity of water, it dissolves into a mucilaginous fluid, of the consistence of a thick syrup, and in this state answers many useful pharmaceutical purposes, by rendering oily, resinous, and pinguious substances miscible with water. The glutinous quality of gum-arabic renders it preferable to other gums and mucilages as a demulcent in coughs, hoarsenesses, and other catarrhal affections. It is also very generally employed in ardor urinæ, diarrhœas, and calculous complaints.

2. The name Acacia vera has also been used to denote the expressed juice of the immature pods of the tree; termed also, *acacia veravel.* This inspissated juice is brought from Egypt in roundish masses, wrapped up in thin bladders. It is considered as a mild astringent medicine. The Egyptians give it, in spitting of blood, in the quantity of a drachm, dissolved in any convenient liquor, and repeat this dose occasionally. They likewise employ it in collyria, for strengthening the eyes, and in gargles, for quinsies. It is now seldom used as a medicine, being superseded by the use of catechu, or terra japonica.

The inspissated juice of the unripe sloe is usually sold for the Egyptian acacia.

Aca′cia veravel. See *Acacia vera.*

Aca′cia Zeylo′nica. Logwood. See *Hæmatoxylon Campechianum.*

Aca′lai. (Arab.) Common salt, or muriate of soda.

Aca′lcum. Tin.

Aca′matos. (From *α*, neg. and *καμνω*, to grow weary.) A perfect rest of the muscles.

Aca′nor. (Hebrew.) A chemical furnace.

Aca′ntha. (*Ακανθα*, from *ακη*, a point.) A thorn, or any thing pointed, as the shin, or spina dorsi.

Acantha′bolus. (From *ακανθα*, a thorn, and *βαλλω*, to cast out.) An instrument, or forceps, for taking out or removing thorns, or whatever may stick in the flesh. *Paulus Ægineta.*

Aca′nthe. The name of the artichoke in antient authors.

Aca′nthinum. (From *ακανθα*, a thorn.) Gum-arabic was so called because it is produced from a thorny tree.

Aca′nthulus. (From ακανθα, a thorn.) A surgical instrument to draw out thorns or splinters, or to remove any extraneous matter from wounds.

ACA′NTHUS. (Ακανθος, from ακανθα, a thorn; so named from being rough and prickly.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*. Order, *Angiospermia*. Bear's breech. Brank-ursine.

Acanthus mollis. (Ακανθος, from ακανθα, a thorn, so named from its rough and prickly surface.) Bear's-breech, or Brank-ursine. *Acanthus mollis, foliis sinuatis inermibus* of Linnæus. *Branca ursina* of the shops. The leaves and root abound with a mucilage, which is readily extracted by boiling or infusion. The roots are the most mucilaginous. Where this plant is common, it is employed for the same purposes to which althæa and other vegetables possessing similar qualities are applied among us. It is fallen into disuse. The herb-women too often sell the leaves of helleboraster or bear's-foot, and of spondylium or cow's parsnip, for the bear's-breech.

Aca′pnon. (From α, priv. and καπνος, smoke.) Common wild marjoram. Unsmoked honey.

A′carus. (From ακαρης, small.) An insect which breeds in the skin.

Acatale′psia. (From α, neg. and καταλαμβανω, to apprehend.) Uncertainty in the prognostication or judgment of diseases.

Aca′talis. (From α, neg. and χατεω, to want.) The juniper, named from the abundance of its seeds.

Acata′posis. (From α, neg. and καταπινω, to swallow.) Difficult deglutition.

Aca′statos. (From α, neg. and καθιϛημι, to determine.) Inconstant.

1. Fevers are so called which are anomalous in their appearance and irregular in their paroxysms.

2. Turbid urine without sediment.

Aca′zdir. Tin.

ACCELERA′TOR URI′NÆ. (From *accelero*, to hasten or propel.) *Ejaculator Seminis*. *Bulbo-syndesmo-caverneux* of Dumas. *Bulbo-cavernosus* of Winslow.

A muscle of the penis. It arises fleshy from the *sphincter ani* and membranous part of the urethra, and tendinous from the *crus*, near as far forwards as the beginning of the *corpus cavernosum penis*; the inferior fibres run more transversely, and the superior descend in an oblique direction. It is inserted into a line in the middle of the bulbous part of the urethra, where each joins with its fellow; by which the bulb is completely closed. The use of these muscles is to drive the urine or *semen* forward, and by grasping the bulbous part of the *urethra*, to push the blood towards its *corpus cavernosum*, and the glans, by which they are distended.

Accession. (From *accedo*, to approach.) The approach or commencement of a disease. A term mostly applied to a fever which has paroxysms or exacerbations: thus the accession of fever, means the commencement or approach of the pyrexial period.

ACCESSO′RII OF WILLIS. (*Accessorii*, sc. *nervi*, from *accedo*, to approach; having connection with by contact or approach; so called from the course they take.) The name given by Willis to two nerves, which ascend, one on each side from the second, fourth, and fifth cervical pairs of nerves, through the great foramen of the occipital bone, and pass out again from the *cranium* through the *foramina lacera*, with the *par vagum*, to be distributed on the trapezius muscle.

Accesso′rius. Being connected by contact or approach.

Accesso′rius lumba′lis. A muscle of the loins. See *Sacro-lumbalis*.

A′ccib. An obsolete term for lead.

Acci′piter. (From *accipio*, to take.)

1. The hawk; named from its rapacity.

2. A bandage which was put over the nose; so called from its likeness to the claw of a hawk, or from the tightness of its grasp.

Accipitri′na. (From *accipiter*, the hawk.) The herb hawk-weed, which Pliny says was so called because hawks are used to scratch it, and apply the juice to their eyes to prevent blindness.

Accli′vis. A muscle of the belly, so named from the oblique ascent of its fibres. See *Obliquus internus abdominis*.

Accoucheur. The French for a midwife.

Accouchement. The French for the act of delivery.

Accretion. (From *ad*, and *cresco*, to increase.)

1. Nutrition, growth.

2. The growing together of the fingers or toes.

Accuba′tio. (From *accumbo*, to recline.) Childbed. Reclining.

Ace′dia. (From α, priv. and κηδος, care.) Carelessness, neglect in the application of medicines. Hippocrates sometimes uses this word, in his Treatise on the Glands, to signify fatigue or trouble.

ACE′PHALUS. (Ακεφαλος,) from α, priv. and κεφαλη, a head.) A term applied to monsters born without heads.

A′CER. (*Acer, eris*, neut. from *Acer*, sharp; because of the sharpness of its juice.) The name of a genus of plants in the Linnæan system. Class, *Polygamia*. Order, *Monoecia*.

A′cer pseudopla′tanus. The maple-tree, falsely called sycamore. It is also called *Platanus traga*. This tree is common in England, though not much used in medicine. The juice, if drank while fresh, is said to be a good antiscorbutic. All its parts contain a saccharine fluid; and if the root or branches are wounded in the spring, a large quantity of liquor is discharged, which, when inspissated, yields a brown sort of sugar and syrup like molasses. Large quantities of this sugar are obtained from the trees in New England and Canada, which is much used in France, where it is commonly known by the name of *Saccharum Canadense* or *Saccharum Acernum*, maple sugar. It has been supposed that all Europe might be supplied from the maples of America, but the sugar is coarse and ill tasted.

ACE′RATOS. (From α, neg. and κεραω, or κεραννυμι, to mix.) Unmixed, uncorrupted. This term is applied sometimes to the humours of the body by Hippocrates. Paulus Ægineta mentions a plaster of this name.

ACERB. (*Acerbus*, from *acer*, sharp.) A species of taste which consists in a degree of acidity, with an addition of roughness; properties common to many immature fruits.

ACE′RBITAS. Acidity. Sourness.

ACE′RIDES. (From α, priv. and κηρος, wax.) Soft plasters made without wax.

ACESCENT. Substances which readily run into the acid fermentation.

A′CESIS. (From ακεομαι, to cure.)

1. A remedy or cure.

2. The herb water-sage, so called from its supposed healing qualities.

ACE′STA. (From ακεομαι, to cure.) Distempers which are easily cured.

ACE′STIS. Borax. See *Sodæ subboras*.

ACE′STORIS. (From ακεομαι, to cure.) It strictly signifies a female physician, and is used for a midwife.

ACE′STORIS. A midwife.

ACETA′BULUM. (From *acetum*, vinegar; so called because it resembles the *acetabulum*, or old saucer, in which vinegar was held for the use of the table.) A name given by Latin writers to the cup-like cavity of the os innominatum, which receives the head of the thigh-bone.

ACETA′RIA. (From *acetum*, vinegar; because they are mostly made with vinegar.) Salads or pickles.

ACE′TAS. An acetate. A salt is so called in the new chemical nomenclature and pharmacopœias, which is formed by the union of the acetic acid, with an earthy metallic or alkaline base. Those used in medicine are the acetates of ammonia, lead, potash, and zinc.

ACE′TAS AMMO′NIÆ. Acetate of ammonia. A salt composed of ammonia and acetic acid. It is so deliquescent, that it is always kept in the fluid state. See *Ammoniæ Acetatis Liquor*.

ACE′TAS PLU′MBI. Acetate of lead. A metallic salt composed of oxide of lead and acetic acid, of which there are two varieties. See *Plumbi Superacetas* and *Plumbi Subacetatis Liquor*.

Ace′tas pota′ssæ. See *Potassæ Acetas*.

ACE′TAS ZINCI. A metallic salt composed of zinc and acetic acid. It is used by some as an astringent against inflammation of the eyes, urethra, and vagina, diluted in the same proportion as the sulphate of zinc.

Acetate of Potash. See *Potassæ acetas.*

Acetate of Ammonia. See *Ammoniæ acetatis liquor.*

Acetate of Zinc. See *Acetas Zinci.*

Acetated vegetable Alkali. See *Potassæ acetas.*

Acetated volatile Alkali. See *Ammoniæ acetatis liquor.*

Acetic Acid. See *Acetum.*

ACETIFICATION. A term used by some chemists to denote the action or operation by which vinegar is made.

ACETO′SA. (From *acesco*, to be sour.) Sorrel. A genus of plants in some systems of botany. See *Rumex.*

ACETOSE′LLA. (From *acetosa*, sorrel; from the acidity of its leaves.) Wood-sorrel. See *Oxalis.*

Acetous Acid. Distilled vinegar. See *Acetum.*

Acetous fermentation. See *Fermentation.*

ACE′TUM. (From *acer*, sour.) Vinegar. A sour liquor obtained from many vegetable substances dissolved in boiling water, and from fermented and spirituous liquors, by exposing them to heat and contact with air; under which circumstances they undergo the acid fermentation, (see *Fermentation*,) and afford the liquor called vinegar.

Wine vinegar: — Let any quantity of vinous liquor be mixed with the acid and austere stalks of the vegetable from which wine was prepared. The whole must be frequently stirred, and either exposed to the sun, or deposited in a warm place: after standing a few days it will ferment, become sour, and in a fortnight it will be converted into vinegar.

Cyder vinegar, may be made by fermenting new cyder with the must of apples, in a warm room, or in the open air, where it should be exposed to the sun, and in the course of a week or nine days it will be fit for use.

Another method of preparing vinegar is that published by M. Heber: it consists in exposing a mixture of 72 parts of water, and 4 of rectified malt spirit in a temperature of from 70 to 80° of Fahrenheit, for about two months, at the expiration of which the acetous process will be effected.

Tarragon vinegar is manufactured by infusing one pound of the leaves of that vegetable (which has been gathered a short time before it flowers) in one gallon of the best vinegar, for the space of 14 days; when it should be strained through a flannel bag; and a drachm of isinglass dissolved in cyder must then be added, the whole be carefully mixed and decanted into bottles for a month. Thus the liquor will acquire a most exquisite flavour; it will become remarkably fine, and almost colourless.

The utility of vinegar as a condiment for preserving and seasoning both animal and vegetable substances in various articles of food, is very generally known. It affords an agreeable beverage, when combined with water in the proportion of a tablespoonful of the former to half a pint of the latter. It is often employed as a medicine in inflammatory and putrid diseases, when more active remedies cannot be procured. Relief has likewise been obtained in hypochondriacal and hysteric affections, in vomiting, fainting, and hiccough, by the application of vinegar to the mouth. If this fluid be poured into vessels and placed over the gentle heat of a lamp in the apartments of the sick, it greatly contributes to disperse foul or mephitic vapours, and consequently to purify the air.

Also as an external application, vinegar proves highly efficacious when joined with farinaceous substances, and applied as a cataplasm to sprained joints; it also forms an eligible lotion for inflammations of the surface, when mixed with alcohol and water in about equal proportions. Applied to burns and scalds, vinegar is said to be highly serviceable whether there is a loss of substance or not, and to quicken the exfoliation of carious bone. (Gloucester Infirmary.) Mixed with an infusion of sage, or with water, it forms a popular and excellent gargle for an inflamed throat, also for an injection to moderate the fluor albus. Applied cold to the nose in cases of hæmorrhage, also to the loins and abdomen in menorrhagia, particularly after parturition, it is said to be very serviceable. An imprudent use of vinegar internally is not without considerable inconveniencies. Large and frequent doses injure the stomach, coagulate the chyle, and produce not only leanness, but an atrophy. When taken to excess by females, to reduce a corpulent habit, tubercles in the lungs and a consumption have been the consequence.

Common vinegar consists of acetic acid combined with a large portion of water, and with this are in solution portions of gluten, mucilage, sugar, and extractive matter from which it derives its colour, and frequently some of the vegetable acids, particularly the malic and the tartaric.

Distilled with a gentle fire, in glass vessels, so long as the drops fall free from empyreuma, it affords the

Acidum aceticum.

"Take of vinegar, a gallon.

Distil the acetic acid in a sand bath, from a glass retort into a receiver also of glass, and kept cold; throw away the first pint, and keep for use the six succeeding pints, which are distilled over."

In this distillation, the liquor should be kept moderately boiling, and the heat should not be urged too far, otherwise the distilled acid will have an empyreumatic smell and taste, which it ought not to possess. If the acid be prepared correctly, it will be colourless, and of a grateful, pungent, peculiar acid taste. One fluid-ounce ought to dissolve at least ten grains of carbonate of lime (white marble). This liquor is the *acetum distillatum;* the *acidum acetosum* of the London Pharmacopœia of 1787, and the *acidum aceticum* of the last (1809)

When the acid of vinegar is greatly concentrated, that is, deprived of its water, it becomes the radical vinegar, or

Concentrated acid of vinegar.

Distilled vinegar may be concentrated by freezing: the congelation takes place at a temperature below 28 degrees, more or less, according to its strength; and the congealed part is merely ice, leaving, of course, a stronger acid. If this be exposed to a very intense cold, it shoots into crystals; which, being separated, liquefy, when the temperature rises; and the liquor is limpid as water, extremely strong, and has a highly pungent acetous odour. This is the pure acid of the vinegar, any foreign matter remaining in the uncongealed liquid.

Other methods are likewise employed to obtain the pure and concentrated acid. The process of Westendorf, which has been often followed, is to saturate soda with distilled vinegar, obtain the acetate by crystallization; and pour upon it, in a retort, half its weight of sulphuric acid. By applying heat, the acetic acid is distilled over; and, should there be any reason to suspect the presence of any sulphuric acid, it may be distilled a second time, from a little acetate of soda. According to Lowitz, the best way of obtaining this acid pure, is to mix three parts of the acetate of soda with eight of supersulphate of potass; both salts being perfectly dry, and in fine powder, and to distil from this mixture in a retort, with a gentle heat.

It may also be obtained by distilling the verdigris of commerce, with a gentle heat. The concentrated acid procured by these processes, was supposed to differ materially from the acetous acid obtained by distilling vinegar; the two acids were regarded as differing in their degree of oxygenizement, and were afterwards distinguished by the names of acetous and acetic acids. The acid distilled from verdigris was supposed to derive a quantity of oxygen from the oxide of copper, from which it was expelled. The experiments of Adet have, however, proved the two acids to be identical; the acetous acid, therefore, only differs from the acetic acid in containing more water, rendering it a weaker acid, and of a less active nature.

There exists, therefore, only one acid of vinegar, which is the acetic; and its compounds must be termed *acetates;* and the salts called *acetites* have no existence.

Acetic acid, when concentrated, has a fragrant and, at the same time, very penetrating smell, irritating the nostrils strongly. It is also so caustic, as to inflame the skin. Its acid taste is strong, even when much diluted with water; it is colourless, and has a specific gravity of 1,0626. The acid is capable of congelation, when it forms foliated arborescent crystals; it is very volatile; its odour is diffused through the atmosphere, and, when exposed to it, gradually becomes weaker. By a moderate heat, it is converted into vapour; this vapour readily catches fire on the approach of a lighted taper. It combines with water in every proportion; and it combines readily with earthy, metallic, and alkaline bases, forming salts, which are called acetates.

The compounds of the acid of vinegar, directed to be used by the new London Pharmacopœia, are *acetum colchici, acetum scillæ, ceratum saponis, plumbi superacetas, liquor ammoniæ acetatis, liquor plumbi subacetatis, liquor plumbi sub-acetatis dilutus, oxymel, oxymel scillæ, potassæ acetas*, and the *cataplasma sinapis*.

Ace´tum aroma´ticum. Aromatic vinegar. A preparation of the Edinburgh pharmacopœia, thought to be an improvement of what has been named *thieves vinegar*.

"Take of the dried tops of rosemary; The dried leaves of sage, of each four ounces. Dried lavender flowers, two ounces. Cloves, two drachms. Distilled vinegar, eight pounds. Macerate for seven days, and strain the expressed juice through paper." Its virtues are antiseptic, and it is a useful composition to smell at in crowded courts of justice, hospitals, &c. where the air is offensive.

Ace´tum co´lchici. See *Colchicum*.

Ace´tum distillatum. See *Acetum*.

Ace´tum sci´llæ. Lond. Pharm. Vinegar of squills. "Take of squills recently dried, one pound; vinegar, six pints; proof spirit, half a pint. Macerate the squills with the vinegar in a glass vessel, with a gentle heat for twenty-four hours; then express the liquor and set it aside until the fæces subside. To the decanted liquor add the spirit." This preparation of squills is employed as an attenuant, expectorant, and diuretic. Dose xv. to lx. drops.

A´cheir. (From α, neg. and χειρ, hand.) Without hands.

Achi´colum. By this word Cælius Aurelianus, Acut. lib. iii. cap. 17. expresses the fornix, tholus, or sudatorium of the antient baths, which was a hot room where they used to sweat.

ACHILLE´A. (Αχιλλεια, from Achilles, who is said to have made his tents with it, or to have cured Telephus with it.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*. Order *Polygamia superflua*. Milfoil. Three species of this genus are employed in medicine.

1. Achille´a age´ratum. *Balsamita fœmina. Eupatorium Mesues.* Maudlin or Maudlin tansey. This plant, the ageratum of the shops, is described by Linnæus as *Achillea foliis lanceolatis, obtusis, acutoserratis.* It is esteemed in some countries as anthelminthic and alterative, and is given in hepatic obstructions. It possesses the virtues of tansey.

2. Achille´a millefo´lium. The systematic name of the milfoil. *Achillea. Myriophyllon. Chiliophyllon. Lumbus veneris. Militaris herba. Stratiotes. Carpentaria. Speculum veneris.* Common yarrow, or milfoil. The leaves and flowers of this indigenous plant, *Achillea millefolium* of Linnæus: —*foliis bipinnatis nudis; laciniis linearibus dentatis; caulibus superne sulcatis*, have an agreeable, weak, aromatic smell, and a bitterish, rough, and somewhat pungent taste. They are both directed for medicinal use, in the Edinburgh Pharmacopœia; in the present practice, however, they are almost wholly neglected.

3. Achille´a pta´rmica. The systematic name of the Sneeze-wort *Pseudopyrethrum. Pyrethrum sylvestre. Draco sylvestris. Tarchon sylvestris. Sternutamentoria. Dracunculus pratensis.* Sneeze-wort. Bastard pellitory. *Achillea ptarmica* of Linnæus: —*foliis lanceolatis, acuminatis, argute serratis.* The flowers and roots of this plant have a hot biting taste, approaching to that of pyrethrum, with which they also agree in their pharmaceutical properties. Their principal use is as a masticatory and sternutatory.

Achillea foliis pinnatis. See *Genipi verum.*

ACHI´LLIS TE´NDO. (So called, because, as fable reports, Thetis, the mother of Achilles, held him by that part when she dipped him in the river Styx, to make him invulnerable. Homer describes this tendon, and some writers suppose it was thus named by the antients, from their custom of calling every thing *Achillean*, that had any extraordinary strength or virtue. Others say it was named from its action in conducing to swiftness of pace, the term importing so much.) The strong and powerful tendon which is formed by the junction of the gastrocnemius and soleus muscles, and which extends along the posterior part of the tibia from the calf to the heel. When this tendon is unfortunately cut or ruptured, as it may be in consequence of a violent exertion, or spasm of the muscles, of which it is a continuation, the use of the leg is immediately lost, and unless the part be afterwards successfully united, the patient must remain a cripple for life. When the tendon has been cut, the division of the skin allows the accident to be seen. When the tendon has been ruptured, the patient hears a sound, like that of the smack of a whip, at the moment of the occurrence. In whatever way the tendon has been divided, there is a sudden incapacity, or at least an extreme difficulty, either of standing or walking. Hence the patient falls down, and cannot get up again. Besides these symptoms there is a very palpable depression between the ends of the tendon; which depression is increased when the foot is bent, and diminished, or even quite removed when the foot is extended. The patient can spontaneously bend his foot, none of the flexor muscles being interested. The power of extending the foot is still possible, as the peronei muscles, the tibialis posticus, and long flexors, remain perfect, and may perform this motion. The indications are to bring the ends of the divided parts together, and to keep them so, until they have become firmly united. The first object is easily fulfilled by putting the foot in a state of complete extension; the second, namely, that of keeping the ends of the tendon in contact, is more difficult. It seems unnecessary to enumerate the various plans devised to accomplish these ends. The following is Desault's method: After the ends of the tendon had been brought into contact by moderate flexion of the knee, and complete extension of the foot, he used to fill up the hollows on each side of the tendon with soft lint and compresses. The roller applied to the limb, made as much pressure on these compresses as on the tendon, and hence this part could not be depressed too much against the subjacent parts. Desault next took a compress about two inches broad, and long enough to reach from the toes to the middle of the thigh, and placed it under the foot, over the back of the leg and lower part of the thigh. He then began to apply a few circles of a roller round the end of the foot, so as to fix the lower extremity of the longitudinal compress: after covering the whole foot with the roller, he used to make the bandage describe the figure of 8, passing it under the foot and across the place where the tendon was ruptured, and the method was finished by encircling the limb upward with the roller as far as the upper end of the longitudinal compress.

A′CHLYS. (Αχλυς.) Darkness, cloudiness. It is generally applied to a close, foggy air, or a mist.

Hippocrates, De Morbis Mulierum, lib. ii. signifies by this word condensed air in the womb.

Galen interprets it of those, who, during sickness, lose that usual lustre and loveliness observed about the pupil of the eye during health.

Others express it by an ulcer on the pupil of the eye, or the scar left there by an ulcer.

It means also an opacity of the cornea; the same as the caligo cornea of Dr. Cullen.

ACHMA′DIUM. Antimony.

ACHME′LLA. See *Spilanthus*.

A′CHNE. Chaff, scum or froth of the sea. A white mucus in the fauces, thrown up from the lungs, like froth; also a whitish mucilage in the eyes of those who have fevers, according to Hippocrates. It signifies also lint.

A′CHOLUS. Deficient in bile.

A′CHOR. (αχωϱ, qu. αχνωϱ, from αχνη, bran; according to Blanchard it is derived from α, priv. and χωϱος space, as occupying but a small compass.) *Lactumen: abas: acores: cerion: favus. Crusta lactea* of authors. The scald-head; so called from the branny scales thrown off it. A disease which attacks the hairy scalp of the head, for the most part of young children, forming soft and scaly eruptions. Dr. Willan, in his description of different kinds of pustules, defines the achor, a pustule of intermediate size between the phlyzacium and psydracium, which contains a straw-coloured fluid, having the appearance and nearly the consistence of strained honey. It appears most frequently about the head, and is succeeded by a dull white or yellowish scab. Pustules of this kind, when so large as nearly to equal the size of phlyzacia, are termed ceria or favi, being succeeded by a yellow, semi-transparent, and sometimes, cellular scab, like a honey-comb. The achor differs from the favus and tinea only in the degree of virulence. It is called favus when the perforations are large; and tinea when they are like those which are made by moths in cloth: but generally by tinea is understood a dry scab on the hairy scalp of children, with thick scales and an offensive smell. When this disorder affects the face, it is called crusta lactea or milk scab. Mr. Bell, in his treatise on Ulcers, reduces the tinea capitis and crusta lactea to the same species of herpes, *viz.* the herpes pustulosus, differing only in situation. See *Crusta Lactea.*

ACHORI′STOS. Inseparable. It is understood of accidents, symptoms, or signs, which are inseparable from particular things. Thus, a pungent pain in the side is an inseparable symptom of a pleurisy.

ACHREI′ON. Useless. It is applied by Hippocrates to the limbs which, through weakness, are become useless.

ACHROI′A. A paleness.

A′CHYRON, (αχυϱον.) This properly signifies bran or chaff, or straw.

Hippocrates, de Morbis Mulierum, most probably means by this word, bran. Achyron also signifies a straw, hair, or any thing that sticks upon a wall.

A′CIA. (From ακη, a point.) A needle with thread in it for chirurgical operations.

A′CICYS. It signifies weak, infirm, or faint, and in this sense it is used by Hippocrates, De Morb. lib. iv.

ACID. That which impresses upon the organs of taste a sharp or sour sensation. Acids are defined by modern chemists to be salts of a sour taste, changing the blue colour of various vegetable pigments to a red. The word *sour*, which is usually employed to denote the simple impression, or lively and sharp sensation produced on the tongue by certain bodies, may be regarded as synonymous to the word *acid*. The only difference which can be established between them is, that the one denotes a weak sensation, whereas the other comprehends all the degrees of force from the least perceptible to the greatest degree of causticity: thus we say that verjuice, gooseberries, or lemons, are *sour;* but we use the word acid to express the impression which the nitric, sulphuric, or muriatic acids make upon the tongue. The vegetable pigments usually employed to ascertain the presence of acids are tincture of turnsole or litmus, and syrup of violets. Acids readily combine with alkalis, earths, and metallic oxides, and form neutral salts. The characteristics, therefore, of an acid, are,

1. A peculiar taste termed acid.

2. Its changing blue vegetable juices red.

3. Combining with alkalis, earths, and metallic oxides.

Acids, according to the kingdom of nature in which they are found, are divided into mineral, vegetable, and animal.

The mineral acids as yet known, are the sulphuric or vitriolic, the nitric, muriatic, carbonic, boracic, fluoric, succinic, arsenic, molybdic, tungstic, and chromic.

The vegetable acids are, the acetic, oxalic, tartaric, pyrotartaric, gallic, citric, malic, benzoic, pyroligneous, pyromucous, camphoric, and kinic.

Of the animal acids there are seven, *viz.* the phosphoric, lactic, saccholactic, formic, prussic, bombic, and lithic, or uric.

Experiment proves that most acids consist of a peculiar body combined with the basis of oxygen gas: hence the origin of the word oxygen, which signifies the generation of acid, it being regarded as the *acidifying basis* or principle of acidity. The bodies which form the other constituents of acids, are regarded as the *acidifiable bases:* thus the principles of phosphoric acid are phosphorus and oxygen; those of carbonic acid, carbon and oxygen.

If an acid basis be perfectly saturated with oxygen, the acid, thus produced, is said to be perfect; but if the basis predominate, the acid is considered as imperfect. Modern chemists distinguish these by their termination: the former in Latin by the syllables ICUM, in English IC; and the latter in Latin by OSUM, and in English by OUS: thus the perfect acid of nitre is called *acidum nitricum,* or nitric acid; the imperfect acid of nitre, *acidum nitrosum,* or nitrous acid. If the acidifiable basis be combined with oxygen, yet without showing any of the properties of an acid, the product is then called an oxyd or oxide: thus iron heated and exposed to the air or water attracts the oxygen, and an oxyd of iron is formed. The various acids employed medicinally are, the acetic, benzoic, tartaric, carbonic, citric, muriatic, nitric, sulphuric and phosphoric. To these perhaps might be added the oxymuriatic, or oxygenated muriatic acid, which was maintained by Berthollet to be a compound of muriatic acid and oxygen; but Sir Humphrey Davy considering it as a simple substance, has termed it Chlorine; and it scarcely possesses the characters of an acid.

Acid, aerial. See *Carbonic acid.*

Acid acetic. See *Acetum.*

For the other Acids look to the word *Acidum.*

Acidifiable base. See *Acid.*

Acidifying base. See *Acid.*

ACIDIFICATION. The formation of an acid; also the impregnating of any thing with acid properties.

ACIDITY. *Aciditas.* Sourness.

ACIDS, ANIMAL. Those which are obtained from animals. See *Acid.*

ACIDS DULCIFIED. These are now called Æthers. See *Æther.*

ACIDS IMPERFECT. Those acids are so called in the chemical nomenclature, which are not fully saturated with oxygen. Their names are ended in Latin by *osum,* and in English by *ous:* e. g. acidum nitrosum, or nitrous acid.

ACIDS, MINERAL. Those acids which are found to exist in minerals, as the sulphuric, the nitric, &c. See *Acid.*

ACIDS, PERFECT. An acid is termed perfect in the chemical nomenclature, when it is completely saturated with oxygen. Their names are ended in Latin by *icum,* and in English by *ic:* e. g. *acidum nitricum* or *nitric acid.*

ACIDS, VEGETABLE. Those which are found in the vegetable kingdom, as the citric, malic, acetic, &c. See *Acid.*

ACIDULOUS WATERS. Mineral waters, which contain so great a quantity of carbonic acid gas, as to render them acidulous, or gently tart to the taste. See *Mineral waters.*

A'CIDUM ACE'TICUM. See *Acetum.*

A'CIDUM ACETO'SUM. See *Acetum.*

A'CIDUM ÆTHE'REUM. The sulphuric acid.

A'CIDUM ALUMINO'SUM. The sulphuric acid.

A'CIDUM ARSE'NICUM. See *Arsenic.*

A'CIDUM BENZO'ICUM. See *Benzoic acid.*

A'CIDUM BORA'CICUM. See *Boracic acid.*

A'CIDUM CARBO'NICUM. See *Carbonic acid.*

A'CIDUM CATHO'LICON. The acid of sulphur.

A'CIDUM CI'TRICUM. See *Citric acid.*

A'CIDUM MURI'ATICUM. See *Muriatic acid.*

A'CIDUM NI'TRICUM. See *Nitric acid.*

A'cidum Nítricum dilútum. Take of nitric acid a fluid ounce; distilled water nine fluid ounces. Mix them.

A'CIDUM NITRO'SUM. See *Nitrous acid.*

A'CIDUM PHOSPHO'RICUM. See *Phosphoric acid.*

A'CIDUM PRIMIGE'NIUM. The sulphuric acid.

A'CIDUM SUCCI'NICUM. See *Succinic acid.*

A'CIDUM SULPHU'REUM. See *Sulphurous acid.*

A'CIDUM SULPHU'RICUM. See *Sulphuric acid.*

A'CIDUM SULPHU'RICUM DILU'TUM. *Acidum vitriolicum dilutum. Spiritus vitrioli tenuis.* "Take of sulphuric acid a fluid ounce and a half; distilled water fourteen fluid ounces and a half. Add the water gradually to the acid."

A'CIDUM TARTA'RICUM. See *Tartaric acid.*

A'CIDUM VITRIO'LICUM. See *Sulphuric acid.*

A'CIDUM VITRIO'LICUM DILU'TUM. See *Acidum sulphuricum dilutum.*

A'CIES. Steel.

ACINE'SIA. A loss of motion and strength.

A'CINI BILIO'SI. (*Acinus,* a grape-stone; so called from their supposed resemblance.) The small glandiform bodies of the liver, which separate the bile from the blood, were formerly so called: they are now, however, more properly termed *penicilli.* See *Liver.*

ACINIFORM TUNIC. *Tunica acinosa.* The coat of the eye called the *uvea,* because the antients, who dissected brutes, observed that, in them, it was usually of the colour of an unripe grape.

A'CINUS. (A grape.) The glands which grow together in clusters are called by some *acini glandulosi.*

ACMA'STICOS. A species of synochus, wherein the febrile heat continues of the same tenour to the end. *Actuarius.*

A'CME. (From ακμη, a point.) The height or crisis of a disease. A term applied by physicians to that period or state of a disease in which it is at its height. The antients distinguished diseases into four stages: 1. the *arche,* the beginning or first attack. 2. *Anabasis,* the growth. 3. The *acme,* the height. 4. *Paracme,* or the decline of the disease.

ACME'LLA. See *Spilanthus.*

A'CNE. *Acna.* (ἄκνη.) A small pimple, or hard tubercle on the face. Foesius says, that it is a small pustule or pimple, which arises usually about the time that the body is in full vigour.

ACNE'STIS. (From α, priv. and κναω, to scratch.) That part of the spine of the back, which reaches from the metaphrenon, which is the part betwixt the shoulder-blades, to the loins. This part seems to have been originally called so in quadrupeds only, because they cannot reach it to scratch.

A'COE. (Ακοη.) The sense of hearing.

ACOE'LIUS. (From α, priv. and κοιλια, the belly.) Without belly. It is applied to those who are so wasted, as to appear as if they had no belly. *Galen.*

ACOE'TUS. (Ακοιτος.) An epithet for honey, mentioned by Pliny; because it has no sediment, which is called κοιτη.

ACO'NION. (Ακονιον.) A particular form medicine among the antient physicians, made of powders levigated, and probably like *collyria* for the disorders of the eyes.

ACONI'TUM. (Of this plant various derivations are given by etymologists; as, ακονη a *whetstone* or *rock,* because it is usually found in barren and rocky places: α, neg. and κονις, *dust;* because it grows without earth, or on barren situations: ακοναω, *to sharpen;* because it was used in medicines intended to quicken the sight: ακων, ακη, a *dart;* because they poison darts therewith: or, ακονιζομαι, to accelerate; for it hastens death.) Aconite. Wolf's-bane. Monk's-hood.

1. A genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Trigynia.*

2. The pharmacopœial name of the common, or blue, wolf's-bane.

All the species of this genus of plants have powerful effects on the human body: two are preferred to the rest for medicinal uses.

1. ACONITUM RUPELLUS. Monk's-hood. Aconite. *Camarum. Canicida. Cynoctonum.*

Aconitum: —foliorum laciniis linearibus, supernè latioribus, lineâ exaratis.

The aconite is cultivated in our gardens as an ornament, but is spontaneously produced in Germany, and some other northern parts of Europe. Every part of the plant is strongly poisonous, but the root is unquestionably the most powerful; and when first chewed, imparts a slight sensation of acrimony; but afterwards, an insensibility or stupor at the apex of the tongue, and a pungent heat of the lips, gums, palate, and fauces are perceived, followed with a general tremor and sensation of chilliness. The juice applied to a wound, seemed to affect the whole nervous system; even by keeping it long in the hand, or on the bosom, we are told, unpleasant symptoms have been produced. The fatal symptoms brought on by this poison are, convulsions, giddiness, insanity, violent purgings, both upwards and downwards, faintings, cold sweats, and death itself. Dr. Stoerk appears to be the first who gave the wolf's-bane internally, as a medicine; and since his experiments were published, 1762, it has been generally and successfully employed in Germany and the northern parts of Europe, particularly as a remedy for obstinate rheumatisms; and many cases are related where this disease was of several years duration, and had withstood the efficacy of other powerful medicines, as mercury, opium, antimony, cicuta, &c. yet, in a short time, was entirely cured by the aconitum. Instances are also given us of its good effects in gout, scrophulous swellings, venereal nodes, amaurosis, intermittent fevers, paralysis, ulceration, and scirrhus. This plant has been generally prepared as an extract or inspissated juice, after the manner directed in the pharmacopœia: its efficacy is much diminished on being long kept. Like all virulent medicines, it should first be administered in small doses. Stoerk recommends two grains of the extract to be rubbed into a powder, with two drachms of sugar, and to begin with ten grains of this powder, two or three times a day. We find, however, that the extract is often given from one grain to ten for a dose; and Stoll, Scherekbecker, and others, increased this quantity considerably. Instead of the extract, a tincture has been made of the dried leaves, macerated in six times their weight of spirits of wine, and forty drops given for a dose. Some writers say that the napellus is not poisonous in Sweden, Poland, &c. but it should be noted that the species which is not poisonous, is the Aconitum lycoctonum of Linnæus.

2. Aconi′tum a′nthora. The root is the part of this plant (*Aconitum anthora; floribus pentagynis, foliorum laciniis linearibus* of Linnæus,) which is employed medicinally. Its virtues are similar to those of the *aconitum napellus.*

Aco′nium. A little mortar.

A′copon. (From α, priv. and κοπος, weariness.) It signifies originally whatever is a remedy against weariness, and is used in this sense by Hippocrates. Aph. viii. lib. ii. But in time, the word was applied to certain ointments. According to Galen and Paulus Ægineta, the *Acopa Pharmaca* are remedies for indispositions of body which are caused by long or vehement motion.

A′cor. Acidity. It is sometimes used to express that sourness in the stomach contracted by indigestion, and from whence flatulencies and acid belching arise.

Aco′rdina. An obsolete term for Indian tutty.

Aco′ria. (From α, priv. and κορεω, to satiate.) Insatiability. In Hippocrates, it means a good appetite and digestion.

Acori′tes vinum. (From ακορον, galangal.) A wine mentioned by Dioscorides, made with galangal, liquorice, &c. infused with wine.

ACORN. The fruit of the oak. See *Quercus.*

Acortinus. A lupin.

A′CORUS. (Ακορον, from κορη, the pupil; because it was esteemed good for disorders of the eyes.) The name of a genus of plants in the Linnæan system. Class, *Hexandria.* Order, *Digynia.* Sweet-flag. Sweet-rush. The following species is used medicinally.

A′corus ca′lamus. The systematic name for the calamus aromaticus. *Acorus verus. Calamus odoratus. Calamus vulgaris. Diringa. Jacerantatinga. Typha aromatica. Clava rugosa.* Sweet-flag, or acorus. *Acorus calamus scapi mucrone longissimo foliaceo* of Linnæus. The root has been long employed medicinally. It has a moderately strong aromatic smell, and a warm, pungent, bitterish taste; and is deemed useful as a warm stomachic. Powdered, and mixed with some absorbent, it forms a useful and pleasant dentifrice.

A′corus palu′stris. See *Iris palustris.*

A′corus ve′rus See *Acorus Calamus.*

A′corus vulga′ris. See *Iris palustris.*

A′cos. (From ακεομαι, to heal.) A remedy or cure.

Aco′smia. (From α, neg. and κοσμος, beautiful.) Baldness; ill health: irregularity, particularly of the critical days of fevers.

Aco′ste. (From ακοςη, barley.) An antient food made of barley.

ACOU′STICA. (*Acoustica,* sc. *medicamenta;* ακουςικα from ακουω, to hear.) Remedies which are employed with a view to restore the sense of hearing, when wanting or diminished. No internal remedies of this kind are known to produce any uniform effect.

Acoustic nerves. See *Nerve* and *Portio mollis.*

Acoustic duct. The external passage of the ear.

ACOUSTICS. That branch of general science which treats on the origin, propagation, and perception of sound.

Acra. (Arab.) *Acrai nymphomania.* Excessive venereal appetite. The time of menstruation.

Acrai′pala. (From α, neg. and κραιπαλη, surfeit.) *Acræpalos.* Remedies for the effects of a debauch.

Acra′sia. (From α, and κεϱαω, to mix.) Unhealthiness; also the same with Acratia.

Acrati′a. (From α, and κϱατος, strength.) Weakness or intemperance.

Acrati′sma. (From ακρατον, unmixed wine.) A breakfast among the old Greeks, consisting of a morsel of bread, soaked in pure unmixed wine. The derivation of this word is the same as *Acrasia,* because the wine used on this occasion was not mixed with water.

Acrato meli. (From ακρατον, pure wine; and μελι, honey.) Mulsum, or wine mixed with honey.

A′cre. (From ακρος, extreme.) The extremity of the nose.

A′crea. (From ακϱος, extreme.) *Acroteria.* The extremities, i. e. the legs, arms, nose, and ears.

Acræ′palos. See *Acraipala.*

Acribei′a. (From ακριβης, accurate.) An exact and accurate description and diagnosis, or distinction, of diseases.

ACRID. (*Acris.*) A term employed in medicine to express a taste, the characteristic of which is pungency joined with heat.

ACRIMONY. (*Acrimonia,* from *acris,* acrid.) This term is used to express a quality in substances by which they irritate, corrode, or dissolve others. It has been supposed until very lately, there were acid and alkaline acrimonies in the blood, which produced certain diseases; and although the humoral pathology is nearly exploded, the term venereal acrimony and some others are still and must be retained.

A′cris. Any fractured extremity.

Acri′sia. (From α, priv. and κρινω, to judge or separate.) A turbulent state of a disease, which will scarcely suffer any judgment to be formed thereof.

A′critus. (From α, neg. and κρινω, to judge.) Disease without regular crisis, the event of which it is hazardous to judge.

Acroby′stia. (From ακρος, extreme, and βυω, to cover.) The extremity of the prepuce.

Acrocheire′sis. (From ακρος, extreme, and χειρ, a hand.) An exercise among the antients. Probably a species of wrestling, where they only held by the hands.

Acrochei′ris. (From ακρος, extreme, and χειρ, a hand.) Gorræus says, it signifies the arm from the elbow to the ends of the fingers; χειρ signifying the arm, from the scapula to the fingers' end.

Acrocho′rdon. (From ακρος, extreme, and χορδη, a string.) Galen describes it as a round excrescence on the skin, with a slender base; and that it hath its name because of its situation on the surface of the skin. The Greeks call that excrescence an *achrochordon*, where something hard concretes under the skin, which is rather rough, of the same colour as the skin, slender at the base, and broader above. Their size rarely exceeds that of a bean.

Acroco′lia. (From ακρος, extreme, and κωλον, a limb.) These are the extremities of animals, which are used in food, as the feet of calves, swine, sheep, oxen, or lambs, and of the broths of which, jellies are frequently made. Castellus from Budæus adds, that the internal parts of animals are also called by this name; in English *giblets*.

Achrole′nion. Castellus says it is the same as *Olecranon*.

Acroma′nia. (From ακρος, extreme, and μανια, madness.) Total or incurable madness.

Acro′mion. (From ακρον, extremity, and ωμος, the shoulder.) A process of the scapula or shoulder-blade. See *Scapula*.

Acrompha′lium. (Ακρομφαλον, from ακρος, extreme, and ομφαλος, the navel.) *Acromphalon*. The tip of the navel.

Acro′mphalon. See *Acromphalium*.

Acro′nia. (From ακρον, the extremity.) The amputation of any extremity, as a finger or toe.

Acro′pathos. (From ακρος, extreme, and ϖαθος, a disease.) *Acropathus*. It signifies literally a disease at the top or superior part. Hippocrates in his treatise De Superfœtatione applies it to the internal orifice of the uterus; and in Prædict. lib. ii. to cancers, which appear on the surface of the body.

Acro′pathus. See *Acropathos*.

A′cropis. (From ακρον, the extremity, and οψ, the voice.) Imperfect articulation, from a fault in the tongue.

Acropo′sthia. (From ακρος, extreme, and ϖοσθη, the prepuce.) The extremity of the prepuce; or that part which is cut off in circumcision.

Acro′psilon. (From ακρος, extreme, and ψιλος, naked.) The extremity of the denuded glans penis.

Acro′spelos. (From ακρος, extreme, and ϖελος, black.) *Acrospelus*. The bromus Dioscoridis, or wild oat grass; so called because its ears, or tops, are often of a blackish colour.

Acro′spelus. See *Acrospelos*.

Acrote′ria. (From ακρος, extreme.) The extreme parts of the body, as the hands, feet, nose, &c.

Acroteria′smus. (From ακροτηρια, extremities, and this from ακρος, *summus*.) The amputation of an extremity.

Acrothy′mion. (From ακρος, extreme, and ϑυμος, thyme.) *Acrothymia*. *Acrothymium*. A sort of wart, described by Celsus, as hard, rough, with a narrow basis, and broad top; the top is of the colour of thyme; it easily splits and bleeds. This tumour is also called *Thymus*.

Actæ′a. (From αγω, to break.) *Acte*. The elder-tree, so called from its being easily broken. See *Sambucus*.

A′ctine. The herb *Bunias* or *Napus*.

Actinoboli′smus. (From ακτιν, a ray, and βαλλω, to cast out.) Irradiation. It is applied to the spirits, conveying the inclinations of the mind to the body: it is also called *Diradiatio*.

ACTION. (From *ago*, to act.) Any faculty, power, or function of the body, which, by physiologists, are usually divided into vital, animal, or natural. The vital functions, or actions, are those which are absolutely necessary to life, and without which animals cannot exist; as the action of the heart, lungs, and arteries. The natural functions are those which are instrumental in repairing the several losses which the body sustains: digestion, and the formation of chyle, &c. fall under this head. The animal actions are those which we perform at will, as muscular motion, and all the voluntary motions of the body. Each part of the body is also said to have an action peculiar to itself.

ACTON WATER. A purging water procured from Acton, a village near London, where is a well that affords it. This is one of the strongest purging waters near London; and has been drank in the quantity of from one to three pints in a morning, against scorbutic and cutaneous affections. This medical spring is no longer resorted to by the public.

Actual. This word is applied to any thing endued with a property or virtue which acts by an immediate power inherent in it: it is the reverse of potential; thus, a red-hot iron or fire is called an actual cautery, in contradistinction from caustics, which are called potential cauteries. Boiling water is actually hot; brandy, producing heat in the body, is potentially hot, though of itself cold.

ACTUA′RIUS. This word was originally a title of dignity given to physicians at the court of Constantinople; but became afterwards the proper name of a celebrated Greek physician, John, (the son of Zachary, a Christian writer,) who flourished there about the 12th or 13th century. He is said to be the first Greek author who has treated of mild cathartics, as manna, cassia, &c. though they were long before in use among the Arabians. He appears also to have first noticed distilled waters. His works, however, are chiefly compiled from his predecessors.

Actuation. (From *ago*, to act.) That change wrought on a medicine, or any thing taken into the body, by the vital heat, which is necessary, in order to make it act and have its effect, is called its actuation.

Acu′itas. Acrimony.

Acui′tio. (From *acuo*, to sharpen.) The sharpening an acid medicine by an addition of something more acid; or, in general, the increasing the force of any medicine, by an addition of something that hath the same sort of operation in a greater degree.

A′culon. (From *α*, neg. and *κυλοω*, to roll round; so called because its fruit is not involved in a cup, or sheath, like others.) *Aculos.* The fruit or acorn of the ilex, or scarlet oak.

A′culos. See *Aculon.*

Acu′men. A point. The extremity of a bone.

Acupunctu′ra. (From *acus*, a needle, and *punctura*, a prick.) Acupuncture; bleeding performed by making many small punctures.

A′cureb. *Plumbum*, or lead.

A′curon. (From *α*, neg. and *κυρω*, to happen.) A name of the *Alisma;* so called because it produces no effect if taken internally.

Acuspasto′ris. A name of the *Scandix anthriscus*, the shepherd's needle, or Venus's comb. See *Scandix.*

Acute. *Morbus acutus.* A disease which is attended with violent symptoms, terminates in a few days, and is attended with danger. It is opposed to a chronic disease, which is slow in its progress, and not so generally dangerous.

Acutena′culum. (From *acus*, a needle, and *tenaculum*, a handle.) Heister calls the *portaiguille* by this name. It is the handle for a needle, to make it penetrate easily when stitching a wound.

Acy′isis. (From *α*, neg. and *κυω*, to conceive.) In Vogel's nosology it signifies a defect of conception, or barrenness in women.

A′cyrus. (From *α*, priv. and *κυρος*, authority; so named from its little note in medicine.) The *Arnica montana*, or German leopard's-bane. See *Arnica.*

Adæmo′nia. From *α*, priv. and *δαιμων*, a genius of fortune.) The restlessness and anxiety felt in acute fevers.

Adaiges. Sal-ammoniac, or muriate of ammonia. See *Murias ammoniæ.*

A′damas. (From *α*, neg. and *δαμαω*, to conquer; as not being easily broken.) The adamant or diamond, the most precious of all stones, and which was formerly supposed to possess extraordinary cordial virtues.

Adami′ta. *Adamitum.* A hard stone in the bladder.

Adam's Apple. See *Pomum Adami.*

Adam's needle. *Yucca gloriosa* of Linnæus. The roots of this plant are thick and tuberous, and are used by the Indians instead of bread; being first reduced into a coarse meal. This, however, is only in times of scarcity.

Adanso′nia. (From *Adanson* who first, described the Æthiopian sour gourd, a species of this genus.) *Baobab. Bahobab.* It grows mostly on the west coast of Africa, from the Niger to the kingdom of Benin. The bark is called *lalo;* the negroes dry it in the shade, then powder and keep it in little cotton bags, and put two or three pinches into their food. It is mucilaginous, and powerfully promotes perspiration. The mucilage obtained from this bark is a powerful remedy against the epidemic fevers of the country that produces these trees; so is a decoction of the dried leaves. The fresh fruit is as useful as the leaves, for the same purposes.

Ada′rces. (From *α*, neg. and *δερκω*, to see.) A saltish concretion found about the reeds and grass in marshy grounds in Galatia, and so called because it hides them. It is used to clear the skin with, in leprosies, tetters, &c. Dr. Plott gives an account of this production in his *Natural History of Oxfordshire.* It was formerly in repute for cleansing the skin from freckles.

Adari′ges. An ammoniacal salt.

Ada′rneck. Auripigmentum, or orpiment.

Adarticulation. See *Arthrodia.*

Addepha′gia. (From *ἁδην*, abundantly, and *φαγω*, to eat.) Insatiability. A voracious appetite. See *Bulimia.*

Additame′ntum. (From *addo*, to add.) A term formerly employed as synonymous with *epiphysis*, but now only applied to two portions of sutures of the skull. See *Lambdoidal* and *Squamous Sutures.*

Additame′ntum co′li. See *Appendicula cæci vermiformis.*

ADDU′CTOR. (From *ad* and *duco*, to draw.) A drawer or contractor. A name given to several muscles, whose office is to bring forwards or draw together those parts of the body to which they are annexed.

ADDU′CTOR BRE′VIS FE′MORIS. *Adductor femoris secundus* of Douglas. *Triceps secundus* of Winslow. A muscle, which, with the *adductor longus* and *magnus femoris*, forms the *triceps adductor femoris*. It is situated on the posterior part of the thigh, arising tendinous from the os pubis near its joining with the opposite os pubis below, and behind the *adductor longus femoris*, and is inserted, tendinous and fleshy, into the inner and upper part of the linea aspera, from a little below the trochanter minor, to the beginning of the insertion of the *adductor longus*. See *Triceps adductor femoris*.

Addu′ctor fe′moris pri′mus. See *Adductor longus femoris*.

Addu′ctor fe′moris secu′ndus. See *Adductor brevis femoris*.

Addu′ctor fe′moris te′rtius. See *Adductor magnus femoris*.

Addu′ctor fe′moris qua′rtus. See *Adductor magnus femoris*.

ADDU′CTOR I′NDICIS PE′DIS. An external interosseous muscle of the fore-toe, which arises tendinous and fleshy, by two origins, from the root of the inside of the metatarsal bone of the fore-toe, from the outside of the root of the metatarsal bone of the great toe, and from the os cuneiforme internum. It is inserted, tendinous, into the inside of the root of the first joint of the fore-toe. Its use is to pull the fore-toe inwards from the rest of the small toes.

ADDU′CTOR LO′NGUS FE′MORIS. *Adductor femoris primus* of Douglas. *Triceps minus* of Winslow. A muscle situated on the posterior part of the thigh, which, with the *adductor brevis*, and *magnus femoris*, forms the *triceps adductor femoris*. It arises by a pretty strong roundish tendon, from the upper and interior part of the os pubis, and ligament of its synchondrosis, on the inner side of the pectineus, and is inserted along the middle part of the linea aspera. See *Triceps adductor femoris*.

ADDU′CTOR MA′GNUS FE′MORIS. *Adductor femoris tertius et quartus* of Douglas. *Triceps magnus* of Winslow. A muscle which, with the *adductor brevis femoris*, and the *adductor longus femoris*, forms the *Triceps adductor femoris*. It arises from the symphysis pubis, and all along the flat edge of the thyroid foramen, from whence it goes to be inserted into the linea aspera throughout its whole length. See *Triceps adductor femoris*.

ADDU′CTOR MI′NIMI DI′GITI PE′DIS. An internal interosseous muscle of the foot. It arises, tendinous and fleshy, from the inside of the root of the metatarsal bone of the little toe. It is inserted, tendinous, into the inside of the root of the first joint of the little toe. Its use is to pull the little toe inwards.

Addu′ctor o′culi. See *Rectus internus oculi*.

Addu′ctor po′llicis. See *Adductor pollicis manûs*.

ADDU′CTOR PO′LLICIS MA′NUS. *Adductor pollicis*. *Adductor ad minimum digitum*. A muscle of the thumb, situated on the hand, which arises, fleshy, from almost the whole length of the metacarpal bone that sustains the middle finger; from thence its fibres are collected together. It is inserted, tendinous, into the inner part of the root of the first bone of the thumb. Its use is to pull the thumb towards the fingers.

ADDU′CTOR PO′LLICIS PE′DIS. *Antithenar* of Winslow. A muscle of the great toe, situated on the foot: it arises, by a long thin tendon, from the os calcis, from the os cuboides, from the os cuneiforme externum, and from the root of the metatarsal bone of the second toe. It is inserted into the external os sesamoideum, and root of the metatarsal bone of the great toe. Its use is to bring this toe nearer to the rest.

Addu′ctor pro′statæ. A name given by Sanctorini to a muscle, which he also calls *Levator prostatæ*, and which Winslow calls *Prostaticus superior*. Albinus, from its office, had very properly called it *compressor prostatæ*.

ADDU′CTOR TE′RTII DI′GITI PE′DIS. An external interosseous muscle of the foot, that arises, tendinous and fleshy, from the roots of the metatarsal bones of the third and little toe. It is inserted, tendinous, into the outside of the root of the first joint of the third toe. Its use is to pull the third toe outward.

A′dec. Sour milk, or butter-milk.

Ade′cia. See *Adectos*.

Ade′ctos. *Adecia*. (From α, priv. and δακνω, to bite.) An epithet of those medicines which relieve from pain, by removing the uneasy situation caused by the stimulus of acrimonious medicines.

Ade′lphia. (Ἀδελφια, a relation.) Hippocrates calls diseases by this name that resemble each other.

Ademo′nia. (From α, priv. and δαιμων, a genius or divinity or fortune.) Hippocrates uses this word for uneasiness, restlessness, or anxiety felt in acute diseases, and some hysteric fits.

A′DEN. (Αδην, a gland.) A gland. A bubo. See *Gland*.

Ade′niform. (*Adeniformis*; from *aden*, a gland, and *forma*, resemblance.) Glandiform, or resembling a gland. A term sometimes applied to the prostate gland.

Adende′ntes. An epithet applied to ulcers which eat and destroy the glands.

ADENO′GRAPHY. (From αδην, a gland, and γραφω, to write.) A treatise on the glands. See *Gland*.

Adenoi′des. Glandiform: resembling a gland. An epithet applied also to the prostate gland.

ADENO′LOGY. (From αδην, a gland, and λογος, a treatise.) The doctrine of the glands. See *Gland*.

Adenous abscess. (*Abscessus adenosus*; from αδην, a gland.) A hard glandular abscess, which suppurates slowly.

Adepha′gia. (From αδην, abundantly, and φαγω, to eat.) Insatiable appetite. See *Bulimia.*

A′DEPS. (*Adeps, ipis,* m. and f.) Fat. An oily secretion from the blood into the cells of the cellular membrane. See *Fat.*

A′DEPS ANSERI′NUS. Goose-grease.

A′DEPS SUI′LLA. Hog's-lard.

Ade′pta Medici′na. So Paracelsus calls that which treats of the diseases that are contracted by celestial operations, or communicated from heaven.

Ade′pta Philoso′phia. Adept philosophy. It is that philosophy, whose end is the transmutation of metals, and an universal remedy.

Adepts. (From *adipiscor,* to obtain.) Skilful alchymists. Such are called so as pretend to some extraordinary skill in chemistry; but these have too often proved either enthusiasts or impostors. The professors of the *Adepta Philosophia* are also called Adepts.

Adfla′tus. A blast: a kind of erysipelas.

Adhato′da. The Malabar nut-tree, which is a species of *Justicia.* It is used in India for expelling the dead fœtus in an abortion, which, it is said, is the meaning of the word in the Zeylanic language.

ADHÆSION. (From *adhæreo,* to stick to.) The growing together of parts.

ADHÆSIVE INFLAMMATION. A term lately introduced into Surgery, to express that species of inflammation which terminates by an adhesion of the inflamed surfaces.

Adhæsive plaster. A plaster made of common litharge plaster and resin, is so called because it is used for its adhesive properties. See *Emplastrum resinæ.*

Adiachy′tos. (From α, neg. and διαχὺω, to diffuse, scatter, or be profuse.) Decent in point of dress. Hippocrates thinks the dress of a fop derogatory from the physician, though thereby he hide his ignorance, and obtain the good opinion of his patients.

ADIA′NTHUM. (*Adiantum,* αδιαντον, from α, neg. and διαινω, to grow wet; so called, because its leaves are not easily made wet.) Maidenhair. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia.* Order, *Filices.* The following species is used in medicine.

Adia′nthum capi′llus ve′neris. Maidenhair. The leaves of this plant are somewhat sweet and austere to the palate, and possess mucilaginous qualities. A syrup, the *syrop de capillaire* is prepared from them, which is much esteemed in France. Orange-flower water and a proportion of honey, it is said, are usually added. It acts chiefly as a demulcent, sheathing the inflamed sides of the glottis.

Adia′nthum au′reum. The golden maiden-hair. See *Polytrichum.*

Adiaphorous. A term which implies the same with neutral; and is particularly used of some spirits and salts, which are neither of an acid nor alkaline nature.

Adiapneu′stia. (From the privative particle α, and διαπνεω, *perspiro.*) A diminution or obstruction of natural perspiration, and that in which the antients chiefly placed the cause of fevers.

Adiarrhœ′a. From α, priv. and διαῤῥεω, to flow out or through.) A total suppression of all the necessary evacuations from the bowels.

Adiathorosus. A spirit distilled from tartar.

Adibat. Mercury.

A′dice. (Αδικη.) A nettle.

ADIPOCI′RE. (French, from *adeps,* fat, and *cera,* wax.) A substance that resembles ammoniacal soap, formed by a conversion of animal matter, placed under certain circumstances, was found by Fourcroy to consist of ammonia, united to a matter intermediate in its properties between fat and wax, which he called *Adipocire.* Whole bodies have been found converted into this substance.

Adipose membrane. (*Membrana adiposa,* from *adeps,* fat.) The fat collected in the cells of the cellular membrane. See *Fat.*

Adi′psa. So the Greeks called medicines, &c. which abate thirst. Hippocrates applied this word to oxymel.

ADI′PSIA. (From α, neg. and διψα, thirst.) A want of thirst. A genus of disease in the class *locales,* and order *dysorexiæ* of Cullen's Nosology. It is mostly symptomatic of some disease of the brain.

Adi′psos. So the Greeks called the Egyptian palm-tree, whose fruit is said to be the *Myrobalans.* The tree is called *adipsos,* because its fruit quencheth thirst. Theophrastus calls this tree *Balanos.* *Adipsos* is also a name for liquorice.

Adi′rige. Ammoniacal salt.

Adjuto′rium. (From *ad* and *juvo,* to help.) A name of the *humerus,* from its usefulness in lifting up the fore-arm.

Adjuva′ntia. Whatever assists in obviating disease.

ADNA′TA TU′NICA. (*Adnata,* from *adnascor,* to grow to.) *Albuginea oculi, Tunica albuginea oculi.* This membrane is mostly confounded with the *conjunctiva.* It is, however, thus formed: five of the muscles which move the eye, take their origin from the bottom of the orbit, and the sixth arises from the edge of it; they are all inserted, by a tendinous expansion, into the anterior part of the *tunica sclerotica;* which expansion gives the whiteness peculiar to the fore-part of the eye. It lies betwixt the *sclerotica* and *conjunctiva.*

A′doc. Milk.

Ado′nion. (From Αδωνις, the youth from whose blood it was feigned to have sprung.) *Adonium.* Southernwood.

ADO′PTER. *Tubus intermedius.* A

chemical instrument used to combine retorts to the cucurbits or matrasses in distillation, with retorts instead of receivers.

A′dor. A sort of corn, called also spelta.

A′dos. Water in which red-hot iron is extinguished.

Ad′po′ndus o′mnium. The weight of the whole. These words are inserted in pharmaceutical preparations, or prescriptions, when the last ingredient ought to weigh as much as all the others put together.

Adra rhi′za. Blancard says the root of the Aristolochia is thus named.

Adra′chne. The strawberry bay-tree. A species of *Arbutus.*

A′dram. Fossil salt.

Adrara′gi. (Indian.) Garden-saffron.

Adrobo′lon. (From *αδρος*, large, and *βωλος*, a globe, bole, or mass.) Indian bdellium, which is coarser than the Arabian.

Adstriction. Costiveness.

ADSTRINGENTS. See *Astringents.*

Adustion. An inflammation about the brain, and its membranes, with an hollowness of the eyes, a pale colour, and a dry body.

In surgery, adustion signifies the same as cauterization, and means the application of any substance to the animal body, which acts like fire. The antient surgeons, especially the Arabians, were remarkably fond of having recourse to adustion in local diseases: but the use of actual heat is very rarely admitted by the moderns.

Adventitious. Any thing that accidentally, and not in the common course of natural causes, happens to make a part of another; as the glands in strumous cases are said to be adventitious glands, in distinction from those which are naturally produced. It is also used in opposition to hereditary; thus gout and scrofula are sometimes hereditary, and very often adventitious, they having never before been known in the family.

A′dy. *Abanga.* The palm of the island of St. Thomas, from which is prepared Thernel's restorative.

ADYNA′MIA. (*Αδυναμια*: from *α*, priv. and *δυναμις*, power.) A defect of vital power.

ADYNA′MIÆ. (The plural of *Adynamia.*) The second order of the class *neuroses* of Cullen's Nosology: it comprehends *syncope, dyspepsia, hypochondriasis,* and *chlorosis.*

Ady′namon. (From *α*, neg. and *δυναμις*, strength.) *Adynamum.* Among antient physicians, it signified a kind of weak factitious wine, prepared from must, boiled down with water; to be given to patients to whom pure or genuine wine might be hurtful.

Ædoi′a. (From *αιδως*, modesty; or from *α*, neg. and *ειδω*, to see; as not being decent to the sight.) The pudenda, or parts of generation.

Ædopso′phia. (From *αιδοια*, *pudenda*, and *ψοφεω*, to break wind.) A term used by *Sauvages* and *Sagar*, to signify a flatus from the bladder, or from the womb, making its escape through the vagina.

Ægagro′pilus. (From *αιγαγρος*, a wild goat, and *pila*, a ball.) *Ægagropila.*

1. A ball found in the stomach of deer, goats, hogs, horned cattle, as cows, &c. It consists of hairs which they have swallowed from licking themselves. They are of different degrees of hardness, but have no medicinal virtues. Some rank these balls among the *Bezoars.* Hieronymus Velschius wrote a treatise on the virtues of this.

2. A species of conferva found in Wallenfenmoor, from its resembling these concretions, is also so named.

Æ′gias. A white speck on the pupil of the eye, which occasions a dimness of sight.

Ægi′des. *Aglia.* A disorder of the eyes mentioned by Hippocrates. Foësius thinks the disease consists of small cicatrices in the eye, caused by an afflux of corrosive humours upon the part. But in one passage of Hippocrates, Foësius says it signifies small white concretions of humours which stick upon the pupil, and obscure the sight.

Ægi′dion. A collyrium or ointment for inflammations and defluxions of the eyes.

Æ′gilops. Wild fescue grass. This plant is called *ægilops* from its supposed virtue in curing the disorder named Ægylops. It is a species of *Bromus* in the Linnæan system.

ÆGINE′TA, Pau′lus. A celebrated surgeon of the island of Ægina, from which he derived his name. He is placed by Le Clerc in the fourth century; by others in the seventh. He was eminently skilled in his profession, and his works are frequently cited by Fabricius ab Aquapendente. He is the first author that notices the cathartic quality of rhubarb. He begins his book with the description of the diseases of women; and is said to be the first that deserves the appellation of a man-midwife.

Ægine′tia. Malabrian broom rape. A species of *Orobanche.*

Æ′gis. *Achlys.* A film on the eye.

Ægo′ceras. (From *αιξ*, a goat, and *κερας*, a horn: so called, because the pods were supposed to resemble the horns of a goat.) Fœnugreek. See *Trigonella Fænum-græcum.*

Ægo′lethron. (From *αιξ*, a goat, and *ολεθρος*, destruction; so named from the opinion of its being poisonous to goats.) Tournefort says it is the *Chamærododendron*; now the *Azelæa pontica* of Linnæus.

Ægo′nychon. (From *αιξ*, a goat, and *ονυξ*, a hoof; because of the hardness of the seed.) Gromwell. See *Lithospermum.*

ÆGOPO′DIUM. (From *αιξ*, a goat, and *πους*, a foot; from its supposed resemblance to a goat's foot.) Goatweed. A genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.* The following species was formerly much esteemed.

Ægopo′dium podagra′ria. (*Podagraria*, from its use in curing the *podagra*, or gout.) Goatweed. This plant is sedative, and was formerly applied to mitigate pains of gout, and to relieve piles, but not now employed. In its earlier state it is tender and esculent.

Ægoproso′pon. (From αιξ, a goat, and ϖροσωπον, a face; so called because goats are subject to defects in the eyes, or from having in it some ingredients named after the goat.) A name of a lotion for the eyes, when inflamed.

Æ′GYLOPS. (From αιξ, a goat, and ωψ, an eye.) A disease so named from the supposition that goats were very subject to it. The term means a sore just under the inner angle of the eye. The best modern surgeons seem to consider the ægylops only as a stage of the fistula lachrymalis. Paulus Ægineta calls it anchylops, before it bursts, and ægilops after. When the skin covering the lachrymal sac has been for some time inflamed, or subject to frequent returning inflammations, it most commonly happens that the puncta lachrymalia are affected by it; and the fluid, not having an opportunity of passing off by them, distends the inflamed skin, so that at last it becomes sloughy, and bursts externally. This is that state of the disease which is called perfect *aigylops*, or *ægylops*.

Ægy′ptia musca′ta. See *Hibiscus abelmoschus*.

Ægypti′acum. A name given to different unguents of the detergent or corrosive kind. We meet with a black, a red, a white, a simple, a compound, and a magistral Ægyptiacum. The simple Ægyptiacum, which is that usually found in our shops, is a composition of verdigrise, vinegar, and honey, boiled to a consistence. It is usually supposed to take its name from its dark colour, wherein it resembles that of the natives of Egypt. It is improperly called an unguent, as there is no oil, or rather fat, in it.

Ægy′ptium Pha′rmacum ad au′res. Aëtius speaks of this as excellent for deterging fœtid ulcers of the ears, which he says it cures, though the patient were born with them.

Aei′gluces. (From αει, always, and γλυκυς, sweet.) A sweetish wine, or must.

Aeipathei′a. (From αει, always, and ϖαθος, a disease.) Any disease of long duration.

Ænea. (From *æs*, brass, so called because it was formerly made of brass.) A catheter.

Æ′on. The spinal marrow.

Æone′sis. Fermentation. Sprinkling of the whole body.

Æo′nion. The sedum majus, or common house-leek.

Æo′ra. (From αιωϱεω, to lift up, to suspend on high.) Exercise without muscular action; as swinging. A species of exercise used by the ancients, and of which Aëtius gives the following account. Gestation, while it exercises the body, the body seems to be at rest. Of the motion there are several kinds. First, swinging in a hammock, which, at the decline of a fever, is beneficial. Secondly, being carried in a litter, in which the patient either sits, or lies along. It is useful when the gout, stone, or such other disorder, attends, as does not admit of violent motions. Thirdly, riding in a chariot, which is of service in most chronical disorders; especially before the more violent exercises can be admitted. Fourthly, sailing in a ship, or boat. This produces various effects, according to the different agitation of the waters, and, in many tedious chronical disorders, is efficacious beyond what is observed from the most skilful administration of drugs. These are instances of a passive exercise.

Æ′que. Equally. The same as *ana*.

A′ER. The fluid which surrounds the globe. See *Air* and *Atmosphere*.

Æ′pos. An excrescence, or protuberance.

Æ′ra. Darnel, or lolium.

Æri′tis. The *Anagallis*, or pimpernell.

AEROLO′GIA. (Αεϱολογια: from αηϱ, the air, and λογος, a discourse.) *Aerologice*. Aerology. That part of medicine which treats of the nature and properties of air.

Aerolo′gice. See *Aerologia*.

Aero′meli. Honey dew; also a name for manna.

Aero′phobi. (From αηϱ, air, and φοϐος. fear.) According to Cœlius Aurelianus, some phrenetic patients are afraid of a lucid, and others of an obscure air: and these he calls *aerophobi*.

Aeropho′bia. Fear of air, or wind. A symptom of the phrenitis; also a name of *Hydrophobia*.

Aero′sis. The aerial vital spirit of the antients.

Æro′sus lapis. So Pliny calls the *Lapis Calaminaris*, upon the supposition that it was a copper ore.

Æru′ca. Verdigrise.

Æru′go. (*Ærugo, ginis*, f. from *æs*, copper.)

1. The rust of any metal, particularly of copper.
2. Verdigrise. See *Verdigrise*.

Æru′go præpara′ta. See Verdigrise.

Æschromythe′sis. The obscene language of the delirious.

ÆSCULA′PIUS, worshipped by the antients as the god of medicine, was said to be the son of Apollo, by the nymph Coronis, born at Epidaurus, and educated by Chiron, who taught him to cure the most dangerous diseases, and even raise the dead. His history is so involved in fable, that it is useless to trace it minutely. His two sons Machaon and Podalirius, who ruled over a small city in Thessaly, after his death accompanied the Greeks to the siege of Troy: but Homer speaks merely of their skill in the treatment of wounds; and divine honours were not paid to their father till a later period. In the temples raised to him votive tablets were hung up, on which were recorded the diseases cured, as they imagined, by his assistance.

Æ'SCULUS. (*Æsculus*, from *esca*, food.) Horse-chesnut. The name of a genus of plants in the Linnæan system. Class, *Heptandria*. Order, *Monogynia*.

Æsculus hippocastanum. The systematic name for the hippocastanum. *Castanea equina, pavina.* Common horse-chesnut. *Æsculus hippocastanum; foliolis septenis* of Linnæus. The fruit, when dried and powdered, is recommended as an errhine. The bark is highly esteemed on the Continent as a febrifuge; and is, by some, considered as being superior in quality to the Peruvian bark. The bark intended for medical use is to be taken from those branches which are neither very young nor very old, and to be exhibited under similar forms and doses as directed with respect to the cortex peruvianus. It rarely disagrees with the stomach; but its astringent effects generally require the occasional administration of a laxative.

During the late scarcity of grain, some attempts were made to obtain starch from the horse-chesnut, and not without success.

Æseca'vum. Aurichalcum, or brass.

Æsta'tes. Freckles in the face; sunburnings.

Æstphara. Incineration, or burning of the flesh, or any other part of the body.

Æstua'rium. A stove for conveying heat to all parts of the body at once. A kind of vapour bath. *Ambrose Parey* calls an instrument thus, which he describes for conveying heat to any particular part. *Palmarius, de morbis contagiosis*, gives a contrivance under this name, for sweating the whole body.

Æstua'tio. The boiling up, or rather the fermenting of liquors when mixed.

Æ'stus vola'ticus. (From *æstus*, heat, and *volo*, to fly.) According to Vogel, synonymous with phlogosis. Sudden heat, or scorching, which soon goes off, but which for a time reddens the face.

Æ'THER. (*Æther, eris*, m. from Αιθηϱ, a supposed fine subtile fluid.) *Liquor æthereus.* Ether. *Æther sulphuricus, nitricus muriaticus*, according to the acid from which it is formed in conjunction with alcohol. A volatile liquor, obtained by distillation, from a mixture of alcohol and a concentrated acid.

The medical properties of æther, when taken internally, are antispasmodic, cordial, and stimulant. Against nervous and typhoid fevers, all nervous diseases, but especially tetanic affections, soporose diseases from debility, asthma, palsy, spasmodic colic, hysteria, &c. it always enjoys some share of reputation. Regular practitioners seldom give so much as empirics, who sometimes venture upon large quantities, with incredible benefit. Applied externally, it is of service in the headache, toothache, and other painful affections. Thus employed, it is capable of producing two very opposite effects, according to its management; for, if it be prevented from evaporating, by covering the place to which it is applied closely with the hand, it proves a powerful stimulant and rubefacient, and excites a sensation of burning heat, as is the case with solutions of camphor in alcohol, or turpentine. In this way it is frequently used for removing pains in the head or teeth. On the contrary, if it be dropped on any part of the body, exposed freely to the air, its rapid evaporation produces an intense degree of cold; and as this is attended with a proportional diminution of bulk in the part applied in this way it has frequently contributed to the reduction of the intestine, in cases of strangulated hernia.

Æthe'rea he'rba. The Eryngium was so called.

Æthereal oil. An animal or vegetable oil, highly rectified, partaking, as it were, of the nature of æther. See *Oleum Æthereum.*

Æ'THER SULPHU'RICUS. *Naptha vitrioli. Æther Vitriolicus.* Sulphuric ether.

"Take of rectified spirit,
Sulphuric acid, of each, by weight, a pound and a half.

Pour the spirit into a glass retort, then gradually add to it the acid, shaking it after each addition, and taking care that their temperature, during the mixture, may not exceed 120 degrees. Immerse the retort very cautiously into a sand bath, previously heated to 200 degrees, so that the liquor may boil as speedily as possible, and let the æther pass over into a tubulated receiver, to the tubulure of which another receiver is applied, and kept cold by immersion in ice, or water. Distil the liquor until a heavier part also begins to pass over, and appear under the æther in the bottom of the receiver. To the liquor which remains in the retort, pour on twelve fluid ounces more of rectified spirit, and repeat the distillation in the same manner."

It is mostly employed as an excitant, nervine, antispasmodic, and diuretic, in cases of spasms, cardialgia, enteralgia, fevers, hysteria, cephalalgia, and spasmodic asthma. The dose is from min. xx to ʒij. Externally it cures toothache, and violent pains in the head. See *Æther.*

Æ'THER RECTIFICA'TUS. *Æther vitriolicus.* Rectified æther.

"Take of sulphuric æther, fourteen fluid ounces.
Fused potash, half an ounce.
Distilled water, two fluid ounces.

Dissolve the potash in the water, and add thereto the æther, shaking them well together, until they are mixed. Lastly, by means of a temperature of about 200 degrees, distil over twelve fluid ounces of rectified æther, from a large retort into a cooled receiver."

Sulphuric æther is impregnated with some sulphurous acid, as is evident in the smell, and with some ætherial oil: and these require a second process to separate them. Potash unites to the acid, and requires to be added in a state of solution, and in sufficient quantities, for the purpose of neutralizing it; and it also forms a soap with the oil. It is advantageous also to use a less quantity of water than exists in the ordinary solution of potash: and therefore the above directions are adopted in the last London Pharmacopœia. For its virtues, see *Æther.*

Æ´THIOPS. A term applied formerly to several preparations, because of a black colour, like the skin of an Æthiopian.

Æ´THIOPS ANTIMONIA´LIS. A preparation of antimony and mercury, once in high repute, and still employed by some practitioners in cutaneous diseases. A few grains are to be given at first, and the quantity increased as the stomach can bear it.

Æ´THIOPS MARTIA´LIS. A preparation of iron, formerly in repute, but now neglected.

Æ´THIOPS MI´NERAL. The substance heretofore known by this name, is called, by the London College, Hydrargyri sulphuretum nigrum, which see.

Æthmoid Artery. See *Ethmoid Artery.*

Æthmoid Bone. See *Ethmoid Bone.*

Æ´THNA. A chemical furnace.

Æ´THOCES. *Ætholices.* Superficial pustules in the skin, raised by heat, as boils, fiery pustules.

ÆTHU´SA. (From αιθουσα, beggarly.) The name of a genus of plants of the Linnæan system. Class, *Pentandria.* Order, *Digynia,* of which the following species is sometimes used medicinally.

ÆTHUSA MEUM. The systematic name of the *meum* of the Pharmacopœias. Called also *Meu, Spignel,* Baldmoney. The root of this plant is recommended as a carminative, stomachic, and for attenuating viscid humours, and appears to be nearly of the same nature as lovage, differing in its smell, being rather more agreeable, somewhat like that of parsnips, but stronger, and being in its taste less sweet, and more warm, or acrid.

ÆTHYA. A mortar.

Æ´TIOI PHLE´BES. Eagle veins. The veins which pass through the temples to the head, were so called formerly by Rufus Ephesius.

ÆTIOLOGY. (Αιτιολογια: from αιτια, a cause, and λογος, a discourse.) The doctrine of the causes of diseases.

AË´TIUS, called *Amidenus,* from the place of his birth, flourished at Alexandria, about the end of the fifth century. He left sixteen books, divided into four *tetrabiblia,* on the practice of physic and surgery, principally collected from Galen and other earlier writers, but with some original observations. He appears very partial to the use of the cautery, both actual and potential, especially in palsy: which plan of treatment Mr. Pott revived in paraphlegia; and it has since often been adopted with success. Aëtius is the earliest writer, who ascribed medical efficacy to the external use of the magnet, particularly in gout and convulsions; but rather on the report of others, than as what he had personally experienced.

ÆTO´CION. *Ætolium.* The granum cnidium.

ÆTO´NYCHUM. See *Lithospermum.*

AFFECTION. (This is expressed in Greek by ϖαθος: hence *pathema, passio.*) This term indicates any existing disorder of the whole body, or a part of it, as hysterics, colic, leprosy. Thus by adding a descriptive epithet to the term affection, most distempers may be expressed. We say febrile affection, cutaneous affection, &c. using the word affection synonymously with disease.

AFFINITY. (*Affinitas,* a proximity of relationship.) The term affinity is used indifferently with attraction. See *Attraction.*

Affinity of Aggregation. See *Attraction.*

Affinity of Composition. See *Attraction.*

Affinity, Compound. When three or more bodies, on account of their mutual affinity, unite and form one homogeneous body, then the affinity is termed compound affinity or attraction: thus, if to a solution of sugar and water be added spirits of wine, these three bodies will form an homogeneous liquid by compound affinity. See *Attraction.*

Affinity Divellent. See *Affinity Quiescent.*

Affinity, Double. Double elective attraction. When two bodies, each consisting of two elementary parts, come into contact, and are decomposed, so that their elements become reciprocally united, and produce two new compound bodies, the decomposition is then termed, decomposition by double affinity: thus, if we add common salt, which consists of muriatic acid and soda, to nitrate of silver, which is composed of nitric acid and oxyde of silver, these two bodies will be decompounded; for the nitric acid unites with the soda, and the oxide of silver with the muriatic acid, and thus may be obtained two new bodies. The common salt and nitrate of silver therefore mutually decompose each other by what is called double affinity. See *Attraction.*

Affinity, Intermediate. Appropriate affinity. Affinity of an intermedium is, when two substances of different kinds, that show to one another no component affinity, do, by the assistance of a third, combine, and unite into an homogeneous whole: thus, oil and water are substances of different kinds, which, by means of alkali, combine and unite into an homogeneous substance: hence the theory of lixiviums, of washing, &c. See *Attraction.*

Affinity, Quiescent. Mr. Kirwan employs the term *Quiescent affinity* to mark that, by virtue of which, the principles of each compound, decomposed by double affinity, adhere to each other; and *Divellent affinity*, to distinguish that by which the principles of one body unite and change order with those of the other; thus sulphate of potash or vitriolated tartar is not completely decomposed by the nitric acid or by lime, when either of these principles is separately presented; but if the nitric acid be combined with lime, this nitrate of lime will decompose the sulphate of potash. In this last case the affinity of the sulphuric acid with the alkali is weakened by its affinity to the lime. This acid, therefore, is subject to two affinities, the one which retains it to the alkali, called quiescent, and the other which attracts it towards the lime, called divellent affinity.

Affinity, reciprocal. When a compound of two bodies is decomposed by a third; the separated principle being in its turn capable of decomposing the new combination: thus ammonia and magnesia will separate each other from muriatic acid.

Affinity, simple. Single elective attraction. If a body consisting of two component parts, be decomposed on the approach of a third, which has a greater affinity with one of those component parts than they have for each other, then the decomposition is termed, decomposition by simple affinity; for instance, if pure potash be added to a combination of nitric acid and lime, the union which existed between these two bodies will cease, because the potash combines with the nitric acid, and the lime being disengaged, is precipitated. The reason is, that the nitric acid has a greater affinity for the pure potash than for the lime, therefore it deserts the lime, to combine with the potash. When two bodies only enter into chemical union, the affinity, which was the cause of it, is also termed simple or single elective attraction; thus the solution of sugar in water is produced by simple affinity, because there are but two bodies. See *Attraction.*

A′ffion. *Affium.* An Arabic name for opium.

A′ffium. See *Affion.*

Affla′tus. (From *ad* and *flare*, to blow.) A vapour or blast. A species of erysipelas, which attacks people suddenly, so named upon the erroneous supposition that it was produced by some unwholesome wind blowing on the part.

Affu′sio. Pouring a liquor upon something; but sometimes it means the same as *suffusio*, a cataract.

After-birth. See *Placenta.*

A′ga Crete′nsium. The small Spanish milk-thistle.

Agalacta′tio. See *Agalactia.*

Agala′ctia. (Αγαλακτια: from α, priv. and γαλα, milk.) *Agalaxis. Agalactio. Agalactatio.* A defect of milk in childbirth.

Agala′ctos. (From α, priv. and γαλα, milk.) An epithet given to women who have no milk when they lie in.

Agala′xis. See *Agalactia.*

Aga′llochi ve′ri li′gnum. See *Lignum Aloes.*

Aga′lluge. *Agallugum.* A name of the agallochum or aromatic aloe.

Agaric. See *Agaricus.*

Agaricoi′des. A species of agaricus or fungus.

AGA′RICUS. (Αγαρικος: from *Agaria*, a town in Asia; or from *Agarus*, a river in Sarmatia, now Malowouda.) Agaric. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia.* Order, *Fungi.* Several species of this genus have been, and still are, used for medicinal and culinary purposes.

Aga′ricus a′lbus. See *Boletus Laricis.*

Aga′ricus campe′stris. There are several species of the *agaricus*, which go by the term mushroom; as the *agaricus chantarellus, deliciosus, violaceus,* &c. but that which is eaten in this country is the *agaricus campestris* of Linnæus. Similar to it in quality is the champignion or *agaricus pratensis.* Broiled with salt and pepper, or stewed with cream and some aromatic, they are extremely delicious, and, if not eaten to excess, salubrious. Great care should be taken to ascertain that they are the true fungus, and not those of a poisonous nature. *Catchup* is made by throwing salt on mushrooms, which causes them to part with their juice.

Aga′ricus chantare′llus. A species of fungus, esteemed a delicacy by the French. Broiled with salt and pepper, it has much the flavour of a roasted cockle.

Aga′ricus chirurgo′rum. See *Boletus Igniarius.*

Aga′ricus cinnamo′meus. Brown Mushroom. A species of agaricus, of a pleasant smell. When broiled, it gives a good flavour.

Aga′ricus delicio′sus. This fungus well seasoned and then broiled has the exact flavour of a roasted muscle. It is in season in September.

Aga′ricus musca′rius. Bug Agaric, so called from its known virtue in destroying bugs. This reddish fungus is the *Agaricus muscarius* of Linnæus: — *stipitatus, lamellis dimidiatis solitariis, stipite volvato, apice dilatato, basi ovato.* The use of this vegetable is not much known in this country. Haller relates that six persons of Lithuania perished at one time, by eating this kind of mushroom, and that in others it has caused delirium. It is employed externally to strumous, phagedenic, and fistulous ulcers, as an escharotic.

Aga′ricus pipera′tus. The plant thus named by Linnæus, is the pepper mushroom, also called pepper agaric. It is the fungus piperatus albus, lacteo-succo turgens of Ray. Fungus albus acris. When freely taken, fatal consequences are related by several writers to have been the result. When this vegetable has even lost its acrid juice by drying, its caustic quality still remains.

Aga′ricus prate′nsis. The Champignion of Hudson's Flora Anglica. This plant has but little smell, and is rather dry, yet when broiled and stewed, communicates a good flavour.

Aga′ricus viola′ceus. Violet mushroom. This fungus requires much broiling, but when sufficiently done and seasoned, it is as delicious as an oyster. Hudson's bulbosus is only a variety of this.

AGE. The antients reckoned six stages of life: *pueritia*, childhood, which is to the fifth year of our *age*; — *adolescentia*, youth, reckoned to the eighteenth, and youth properly so called, to the twenty-fifth year; — *juventus*, reckoned from the twenty-fifth to the thirty-fifth year; — *virilis ætas*, manhood, from the thirty-fifth to the fiftieth year; — *senectus*, old *age*, from fifty to sixty; — *crepita ætas*, decrepid age, which ends in death.

Agenne′sia. (Αγεννησια: from α, neg. γενναω, to beget.) Impotency in man. A term employed by Vogel. It is synonymous with *anaphrodisia* and *dyspermatismus*.

A′ger. The common earth or soil.

A′ger natu′ræ. The womb.

Agera′tus la′pis (*Ageratus* common.) A stone used by coblers. It is ridiculously said to be discutient and gently astringent. If it possess any such virtues, it probably contains iron; a supposition countenanced by its being used in dyeing.

Age′ratum. (Αγηρατον: from α, priv. and γηρας, *senectus*; never old, ever green; because its flowers preserve their beauty a long time.) See *Achillæa ageratum*.

A′ges. (From αγης, wicked; so called because it is generally the instrument of wicked acts.) The palm or hollow of the hand.

AGEU′STIA. (From α, neg. and γευομαι, *gusto*, to taste.) *Agheustia*, *Apogeustia*, *Apogeusis*. A defect or loss of taste. A genus of disease in the class *locales*, and order *dysæsthesiæ* of Cullen. The causes are fever or palsy, whence he forms two species; the latter he calls *organic*, arising from some affection in the membrane of the tongue, by which relishing things, or those which have some taste, are prevented from coming into contact with the nerves; the other *atonic*, arising without any affection of the tongue.

Agglutina′ntia. Adhesive medicines which heal by causing the parts to stick together.

Agglutina′tio. Agglutination. The adhesive union or sticking together of substances.

Aggluti′tio. Obstruction in the œsophagus, or a difficulty in swallowing.

Aggregate glands. (From *aggrego*, to assemble together.) An assemblage of glands, as those of the intestines.

Aggregation, affinity of. See *Attraction*.

Agheu′stia. See *Ageustia*.

A′gis. The thigh or femur.

Agitato′ria. Convulsive diseases, or those called clonic.

Aglacta′tio. Defect of milk.

Agla′xis. The same.

Aglia. *Aglium*. A shining tubercle r pustule on the face. White specks on the eye. See *Ægides*.

A′gma. *Agme*. A fracture.

A′gnacal. A tree, which, according to Ray, grows about the isthmus of Darien, and resembles a pear-tree, whose fruit is a great provocative to venery.

Agna′ta. See *Adnata tunica*.

Agni′na membra′na. (From *agnus*, a lamb, and *membrana*, a membrane.) Aëtius calls one of the membranes which involve the fœtus by this name, which he derives from its tenderness. See *Amnios*.

Agnoi′a. (From α, priv. and γινωσκω, to know.) Forgetfulness; a symptomatic affection in fevers.

A′gnus ca′stus. (From *agnus*, a lamb; so called from the down upon its surface, which resembles that upon a lamb's skin; and *castus*, because the chaste matrons, at the feasts of Ceres, strewed them upon their beds, and lay upon them.) The *Chaste Tree*. See *Vitex*.

Ago′ge. The deduction or reasoning upon diseases from their symptoms and appearances. The order, state, or tenour of a disease or body.

Agomphi′asis. A looseness of the teeth.

A′gone. (Αγονη: from α, neg. and γονος, offspring.) Hyoscyamus or Henbane; so called because it was supposed to cause barrenness.

Ago′nia. Sterility, impotence, agony.

Agoni′sticum. (Αγωνιϛικον, from αγωνιαω, to struggle.) A term used by antient physicians to signify water extremely cold, which was directed to be given in large quantities, in acute erysipelatous fevers, with a view of overpowering or struggling with the febrile heat of the blood.

A′gonos. (From α, priv. and γονος, or γονη, an offspring; barren.) Hippocrates calls those women so who have not children, though they might have if the impediment were removed.

Ago′stos. (From αγω, to bring, or lead.) That part of the arm from the elbow to the fingers; also the palm or hollow of the hand.

Agre′sta. (Αγριος, wild.) Verjuice, which is made from the wild apple. The immature fruit of the vine.

Agre′sten. A name for the common tartar.

Agre′stis. In the works of some old writers it expresses an ungovernable malignity in a disease.

A′gria. 1. A name of the Ilex aquifolium or Holly.

2. A malignant pustule, of which, the antient surgeons describe two sorts; one which has been so called, is small, and casts a roughness or redness over the skin, slightly corroding it, smooth about its center, spreads slowly, and is of a round figure; this sort is cured by rubbing it with the fasting spittle. The second ulcerates, with a violent redness and

corrosion, so as to make the hair fall off; it is of an unequal form, and turns leprous; it is cured, by the application of pellitory of the wall in the manner of a poultice.

Agria′mpelos. (From αγριος, wild, and αμπελος, a vine.) The wild vine, or white bryony. See *Bryonia.*

Agrielæ′a. (From αγριος, wild, and ελαια, the olive-tree.) The oleaster, or wild olive.

Agrifo′lium. (From ακις, a prickle, and φυλλόν, a leaf.) Aquifolium, or holly tree. It should rather be called acifolium from its prickly leaves.

AGRIMO′NIA. (From αγρος, a field, and μονος, alone: so named from its being the chief of all wild herbs.) Agrimony.

1. The name of a genus of plants in the Linnæan system.

2. The pharmacopœial name of a plant; the common agrimony. *Agrimonia Eupatoria* of Linnæus: —*foliis caulinis pinnatis, foliolis undique serratis, omnibus minutis interstinctis, fructibus hispidis.* It is common in fields about hedges and shady places, flowering in June and July. It has been principally regarded in the character of a mild astringent and corroborant, and many authors recommend it as a deobstruent, especially in hepatic and other visceral obstructions. Chomel relates two instances of its successful use in cases where the liver was much enlarged and indurated. It has been used with advantage in hæmorrhagic affections, and to give tone to a lax and weak state of the solids. In cutaneous disorders, particularly in scabies, we have been told that it manifests great efficacy; for this purpose it was given infused with liquorice in the form of tea; but according to Alston it should be always exhibited in the state of powder. It is best used while fresh, and the tops, before the flowers are formed, possess the most virtue. Cullen observes that the agrimony has some astringent powers, but they are feeble; and pays little attention to what has been said in its favour.

Agrimonia Eupatoria. See *Agrimonia.*

Agrimony. See Agrimonia.

Agrimony, hemp. The Bidens tripartita of Linnæus.

Agrioca′rdamum. (From αγριος, wild, and καρδαμον, the nasturtium.) Sciatica cresses, or wild garden cress.

Agrioca′stanum. (From αγριος, wild, and καςανον, the chesnut.) Earth-nut or pig-nut.

Agrioci′nara. (From αγριος, wild, and κινκρα, artichoke.) See *Cinara.*

Agriococcime′la. (From αγριος, wild, κοκκος, a berry, and μηλεα, an apple-tree.) The prunus sylvestris.

Agriome′la. The crab apple.

A′grion. *Agriophyllon.* The peucedanum silaus, or hog's fennel, or sulphur wort.

Agriophy′llon. See *Agrion.*

Agriopastina′ca. (From αγριος, wild, and *pastinaca*, a carrot.) Wild carrot, or parsnip.

Agriori′ganum. (From αγριος, wild, and οριγανον, marjoram.) Wild marjoram. See *Origanum.*

Agrioseli′num. (From αγριος, wild, and σελινον, parsley.) Wild parsley. See *Smyrnium.*

Agriosta′ri. (From αγριος, wild, and ςαις, wheat). A species of field-corn, called Triticum creticum.

Agripa′lma. (From αγριος, wild, and ϖαλμα, a palm-tree.) *Agripalma gallis.* The herb mother-wort, or wild palm.

Agripa′lma ga′llis. See *Agripalma.*

Agri′ppæ. Those children which are born with their feet foremost, are so called, because that was said to be the case with Agrippa the Roman, who was named *ab ægro partu*, from his difficult birth. These births, though reckoned preter-natural, are often more safe and easy than the natural.

A′grium. An impure sort of natron, or soda. The purer sort was called halmyrhaga.

A′grom. A disease of the tongue peculiar to the Indians, in which it becomes extremely rough and chopped.

Agru′mina. Leeks, wild onions.

Agry′pnia. (From α, priv. and υπνος, sleep.) Watchfulness: want of sleep.

Agrypnoco′ma. (From αγρυπνος, without sleep, and κωμα, a lethargy.) A lethargic kind of watchfulness, in which the patient is stupidly drowsy, and yet cannot sleep. A species of coma.

Ague. See *Febris Intermittens.*

Ague cake. The popular name for a hard tumour on the left side of the belly, lower than the false ribs in the region of the spleen, said to be the effect of intermittent fevers. However frequent it might have been formerly, it is now very rare, and although then said to be owing to the use of bark, it is now less frequent since the bark has been generally employed.

Ague drops. This is a medicine sold for the cure of agues, composed of arsenite of potash in solution in water.

Ague-free. A name given by some to sassafras on account of its supposed febrifuge virtue.

Ague tree. See *Laurus.*

Agui′a. (From α, priv. and γυιον, a member.) Paralytic debility. Where the use of the members is defective or lost.

A′gul. (Arab.) *Alhagi.* The Syrian thorn. The leaves are purgative.

AGUSTINE. A new earth discovered in the Saxon Beryl, or Beryl of Georgien Stadt, a stone greatly resembling the Beryl of Siberia, by professor Tromsdorff of Erfurth in Germany, to which he has given the name of agustine on account of the property of forming salts which are nearly destitute of taste.

This earth is white and insipid; when moistened with water, it is somewhat ductile, but is not soluble in that fluid. Exposed to a violent heat, it becomes extremely hard, but acquires no taste. It combines with acids, forming salts, which have little or no taste. It does not combine either in the humid or dry way with alkalies, or with their carbonates. It retains carbonic acid but feebly. It dissolves in acids equally well after having been hardened, by exposure to heat, as when newly precipitated. With sulphuric acid it forms a salt which is insipid, and scarcely soluble, but an excess of acid renders it soluble, and capable of crystallizing in stars. With an excess of phosphoric acid it forms a very soluble salt. With nitrous acid it forms a salt scarcely soluble.

Agutiguepoo′bi Brazilie′nsis. (An Indian term.) Arrow-root: dartwort. Esculent and vulnerary, and used by the Indians to cure wounds made by arrows.

Agyion. See *Aguia*.

Agy′rtæ. (From *αγυϱις*, a crowd of people, or a mob; or from *αγειϱω*, to gather together.) It formerly expressed certain strollers who pretended to strange things from supernatural assistances; but of late it is applied to all quack and illiterate dabblers in medicine.

Ahaloth. The Hebrew name of lignum aloes.

Ahame′lla. See *Achmella*.

Aho′vai theveticlush. A chesnut-like fruit of Brazil of a poisonous nature.

Ahu′sal. Orpiment.

Ai′lmad. An Arabian name for antimony.

Aimatei′a. A black bilious and bloody discharge from the bowels.

Aimo′rrhois. See *Hæmorrhois*.

Aimorrhœ′a. See *Hæmorrhagia*.

Aipathei′a. (From *αει* always, and *ϖαθος*, a disease.) A disease of long continuance.

Ai′pi. *Aipima coxera*. *Aipipoca*. Indian words for Cassada. A poisonous root of India.

AIR. Common air. Atmospherical air. The word air seems to have been used at first to denote the atmosphere in general; but philosophers afterwards restricted it to the elastic fluid, which constitutes the greatest and the most important part of the atmosphere, excluding the water and the other foreign bodies which are occasionally found mixed with it. See *Atmosphere*.

Air is an elastic fluid, invisible indeed, but easily recognised by its properties. Its specific gravity, according to the experiments of Sir George Shuckburgh, when the barometer is at 30 inches, and the thermometer between 50 and 60 deg. is 0.0012, or 816 times lighter than water. One hundred cubic inches of air weigh 31 grains troy. But as air is an elastic fluid, and compressed at the surface of the earth by the whole weight of the incumbent atmosphere, its density diminishes according to its height above the surface of the earth. From the experiments of Paschal, Deluc, General Roy, &c., it has been ascertained that the density diminishes in the ratio of the compression. Consequently the density decreases in a geometrical progression, while the heights increase in an arithmetical progression. Bouguer had suspected, from his observations made on the Andes, that at considerable heights the density of the air is no longer proportional to the compressing force; but the experiments of Saussure junior, made upon Mount Rose, have demonstrated the contrary.

Air is dilated by heat. From the experiments of General Roy and Sir George Shuckburgh, compared with those of Trembley, &c., it appears, that at the temperature of 60 deg. every degree of temperature increases the bulk of air about 1-82d part. But the experiments of Mr. Dalton of Manchester, and those of Gay-Lussac, where attention was paid to have the air previously well dried, show that the expansion by one degree of heat is only about 1-480 of the whole volume.

The specific caloric of air, according to the experiments of Dr. Crawford, is 1-79, that of water being reckoned 1.

Although the sky is well known to have a blue colour, yet it cannot be doubted that air itself is altogether colourless and invisible. The blue colour of the sky is occasioned by the vapours which are always mixed with the air, and which have the property of reflecting the blue rays more copiously than any other. This has been proved by the experiments which Saussure made with his *cyanometer* at different heights above the surface of the earth. This consisted of a circular band of paper, divided into 51 parts, each of which were painted with a different shade of blue; beginning with the deepest mixed with black, to the lightest mixed with white. He found that the colour of the sky always corresponds with a deeper shade of blue, the higher the observer is placed above the surface; consequently, at a certain height, the blue will disappear altogether, and the sky appear black; that is to say, will reflect no light at all. The colour becomes aways lighter in proportion to the vapours mixed with the air. Hence it is evidently owing to them.

The property which the air has of supporting combustion, and the necessity of it for respiration, are too well known to require any description.

For many ages, air was considered as an element, or simple substance. For the knowledge of its component parts, we are indebted to the labours of those philosophers in whose hands chemistry advanced with such rapidity during the last forty years of the eighteenth century.

Air is a compound of oxygen and nitrogen: but it becomes a question of considerable consequence to determine the proportion of these two ingredients, and to ascertain whether that proportion is in every case the same. Since nitrogen gas, one of the component parts of that fluid, cannot be separated by any substance with which chemists are acquainted, the analysis of air can only be attempted by exposing it to the action of those bodies which have the property of absorbing its oxygen. By these bodies the oxygen gas is separated, and nitrogen gas is left behind, and the proportion of oxygen may be ascertained by the diminution of bulk; which, once known, it is easy to ascertain the proportion of nitrogen gas, and thus to determine the exact relative quantity of the component parts.

After the composition of the atmosphere was known to philosophers, it was taken for granted that the proportion of its oxygen varies in different times and in different places; and that upon this variation the purity or noxious qualities of air depended. Hence it became an object of the greatest importance to be in possession of a method of determining readily the quantity of oxygen in a given portion of air. Accordingly various methods were proposed, all of them depending upon the property which a variety of bodies possesses of absorbing the oxygen of the air, without acting upon its azot. These bodies were mixed with a certain known quantity of atmospheric air, in graduated glass vessels inverted over water, and the proportion of oxygen was determined by the diminution of bulk. These instruments received the name of *eudiometers*, because they were considered as measures of the purity of air. See *Eudiometer*.

It is considered as established by experiment, that air is composed of 0.21 of oxygen gas, and 0.79 of nitrogen gas by bulk. But as the weight of these two gases is not exactly the same, the proportion of the component parts by weight will differ a little: for as the specific gravity of oxygen gas is to that of nitrogen gas as 135 : 118, it follows that 100 parts of air are composed by weight of

about 76 nitrogen gas
24 oxygen gas
——
100

Having thus ascertained the nature and the proportion of the component parts of air, it remains only to enquire in what manner these component parts are united. Are they merely mixed together mechanically, or are they combined chemically? Is air a mechanical mixture or a chemical compound? Philosophers seem at first to have adopted the former of these opinions, if we except Scheele, who always considered air as a chemical compound. But the supposition that air is a mechanical mixture, by no means agrees with the phenomena which it exhibits. If the two gases were only mixed together, as their specific gravity is different, it is scarcely possible that they would be uniformly mixed in every part of the atmosphere. Even Mr. Dalton's ingenious supposition, that they neither attract nor repel each other, would not account for this equal distribution: for undoubtedly, on that supposition, they would arrange themselves according to their specific gravity. Since, therefore, air is in all places composed of the same ingredients, exactly in the same proportions, it follows that its component parts are not only mixed, but actually combined. When substances differing in specific gravity combine together, the specific gravity of the compound is usually greater than the mean. This holds also with respect to air. The specific gravity, by calculation, amounts only to 0.00119, whereas it actually is 0.0012. But perhaps the specific gravity of nitrogen and oxygen gas can scarcely be considered as known with such precision as to entitle us to draw any consequence from this difference.

The difference between air and a mere mixture of its two component parts, has been demonstrated by the experiments of Morozzo and Humboldt. The artificial mixture is much more diminished by nitrous gas than air, even when the mixture contains less oxygen. It supports flame better and longer, and animals live in it longer than they do in an equal portion of air.

The air is, therefore, to be considered as a chemical compound. Hence the reason that it is in all cases the same, notwithstanding the numerous decomposing processes to which it is subjected. The breathing of animals, combustion, and a thousand other operations, are constantly abstracting its oxygen, and decomposing it. The air thus decomposed or vitiated no doubt ascends in the atmosphere, and is again, by some unknown process or other, reconverted into atmospherical air. But the nature of these changes is at present concealed under an impenetrable veil. *Thomson.*

Air, alkaline. See *Ammonia.*

Air, atmospherical. See *Air.*

Air, azotic. See *Nitrogen gas.*

Air, fixed. See *Carbonic acid gas.*

Air, fluoric. See *Fluoric acid gas.*

Air, hepatic. See *Hydrogen gas, sulphuretted.*

Air, inflammable. See *Hydrogen gas.*

Air, marine. See *Muriatic acid gas.*

Air, nitrous. See *Nitrous gas.*

Air, phlogisticated. See *Nitrogen gas.*

Air, phosphoric. See *Hydrogen gas, phosphuretted.*

Air, sulphureous. See *Sulphurous acid gas.*

Air, vital. See *Oxygen gas.*

AISTHETE′RIUM. (From *αισθανομαι*, to perceive.) The sensorium commune, or common sensory, or seat, or origin of sensation. Cartesius and others say, it is the pineal gland; Willis says, it is where the nerves of the external senses are terminated, which is about the beginning of the medulla oblongata, (or top of the spinal marrow,) in the corpus striatum.

AI′TMAD. Antimony.

AIX LA CHAPE′LLE. Called Aken by the Germans. Thermæ Aquis-granensis. A town in the south of France, where there is a sulphureous water, the most striking feature of which, and what is almost peculiar to it, is the unusual quantity of sulphur it contains; the whole, however, is so far united to a gaseous basis, as to be entirely volatilized by heat; so that none is left in the residuum after evaporation. In colour it is pellucid, in smell sulphureous, and in taste saline, bitterish, and rather alkaline. The temperature of these waters varies considerably, according to the distance from the source and the spring itself. In the well of the hottest bath, it is, according to Lucas, 136°, Monet, 146°; at the fountain where it is drank, it is 112°. This thermal water is much resorted to on the Continent, for a variety of complaints. It is found essentially serviceable in the numerous symptoms of disorders in the stomach and biliary organs, that follow a life of high indulgence in the luxuries of the table; in nephritic cases, which produce pain in the loins, and thick mucous urine with difficult micturition. As the heating qualities of this water are as decided as in any of the mineral springs, it should be avoided in cases of a general inflammatory tendency, in hectic fever and ulceration of the lungs; and in a disposition to active hæmorrhagy. As a hot bath, this water is even more valuable and more extensively employed than as an internal remedy. The baths of Aix la Chapelle may be said to be more particularly medicated than any other that we are acquainted with. They possess both temperature of any degree that can be borne, and a strong impregnation with sulphur in its most active forms, and a quantity of alkali which is sufficient to give it a very soft soapy feel, and to render it more detergent than common water. From these circumstances these baths will be found of particular service in stiffness and rigidity of the joints and ligaments, which is left by the inflammation of gout and rheumatism, and in the debility of palsy, where the highest degree of heat which the skin can bear is required. The sulphureous ingredient renders it highly active in almost every cutaneous eruption, and in general in every foulness of the skin; and here the internal use of the water should attend that of the bath. These waters are also much employed in the distressing debility which follows a long course of mercury and excessive salivation. Aken water is one of the few natural springs, that are hot enough to be employed as a vapour bath, without the addition of artificial heat. It is employed in cases in which the hot bath is used; and is found to be a remarkably powerful auxiliary in curing some of the worst species of cutaneous disorders. With regard to the dose of this water to be begun with, or the degree of heat to bathe in, it is in all cases best to begin with small quantities and low degrees of heat, and gradually increase them, agreeably to the effects and constitution of the patient. The usual time of the year for drinking these waters, is from the beginning of May to the middle of June, or from the middle of August to the latter end of September.

Aizo′on. (From αει always, and ζω to live.) *Aizoum.* An evergreen aquatic plant, like the aloe, said to possess antiscorbutic virtues.

Aja′va. (Indian.) A seed used in the East Indies as a remedy for the colic.

AJUGA. (From α, priv. and ζυγον, a yoke.)

1. The name of a genus of plants in the Linnæan system.

2. The pharmacopœial name of the creeping bugloss. Called also *Consolida media. Bugula.* Upright bugloss. Middle consound. This plant, *Ajuga pyramidalis* of Linnæus: — *tetragono pyramidalis, villosa foliis radicalibus maximis,* possesses subadstringent and bitter qualities: and has been recommended in *phthisis, aphthæ,* and *cynanche.*

Ajuga pyramidalis. See *Ajuga.*

Ajura′rat. Lead.

A′KENSIDE, Mark, an English physician, born at Newcastle-upon-Tyne, in 1721; but more distinguished as a poet, especially for his "Pleasures of the Imagination." After studying at Edinburgh, and graduating at Leyden, he settled in practice; but though appointed physician to the Queen, as well as to St. Thomas's Hospital, he is said not to have been very successful. He died of a putrid fever, in his 49th year. He has left a Dissertation on Dysentery in Latin, admired for its elegance; and several small Tracts in the Philosophical, and London Medical Transactions.

Al. The Arabian article which signifies *the;* it is applied to a word by way of eminence, as the Greek ο is. The Easterns express the superlative by adding *God* thereto, as *the mountain of God,* for the highest mountain; and it is probable that *Al* relates to the word *Alla,* God: so *alchemy,* may be *the chemistry of God,* or the most exalted perfection of chemical science.

A′la. A wing. The arm-pit, so called because it answers to the pit under the wing of a bird.

Ala′bari. Lead.

A′lacab. Sal ammoniac.

Alæfo′rmis. Any thing like a wing.

A′læ au′ris. The upper part of the external ear.

A′læ nasi. Two cartilages of the nose which form the outer part of the nostrils.

A′læ vespertilio′num. That part of the ligaments of the womb, which lies between the tubes and the ovaria; so called from its resemblance to the wing of a bat.

A′læ inte′rnæ mino′res. See *Nymphæ.*

A′lafi. *Alafor. Alafort.* Alkaline.

Alai′a phthi′sis. (From αλαιος, blind, and φθισις, a wasting.) A consumption from a flux of humours from the head.

A'lamad. *Alamed.* Antimony.

Ala'mbic. Mercury.

Alandahla. (Arab. bitter.) The bitter apple, or colocynth.

Alanfu'ta. (Arab.) A vein between the chin and lower lip, which was formerly opened to prevent fœtid breath.

Alapou'li. See *Bilimbi.*

Ala're exte'rnum. A name of the external pterygoid muscle; so called because it takes its rise from the wing-like process of the sphenoid bone.

Ala'ria o'ssa. The wing-like processes of the sphenoid bone.

Ala'ris ve'na. The innermost of the three veins in the bend of the arm.

Alasalet. *Alaset.* Ammoniacum.

Alasi. *Alafor.* An alkaline salt.

Ala'strob. Lead.

A'latan. Litharge.

Alate'rnus. A species of rhamnus.

Ala'ti. Those who have prominent scapulæ like the wings of birds.

Alau'rat. Nitre.

Albadal. An Arabic name for the sesamoid bone of the first joint of the great toe.

Albage'nzi. *Albagiazi.* An Arabic name for the os sacrum.

Albagras nigra. So Avicenna names the lepra ichthyosis. Others call it lepra Græcorum.

Albame'ntum. (From *albus*, white.) The white of an egg.

Alba'num. Urinous salt.

Alba'ra. (Chald.) The white leprosy.

Albaras. Arsenic. A white pustule.

Alba'tio. (From *albus*, white.) *Albificatio.* The calcination or whitening of metals.

A'lberas. (Arab.) White pustules on the face: also staphisagria, because its juice was said to remove these pustules.

Albe'ston. Quick lime.

A'lbetad. Galbanum.

A'lbi sublima'ti. Muriated mercury.

ALBICA'NTIA CO'RPORA. (From *albico*, to grow white.) The glands of a white colour which are usually called Willis's glands, in the brain.

A'lbimec. Orpiment. See *Arsenic.*

Albi'num. See *Gnaphalium.*

ALBI'NUS, Be'rnard Sie'gfred, son of a physician, and professor at Leyden of the same name, was born near the end of the 17th century, and prosecuted his studies with so much zeal and success, that he was appointed, on the recommendation of Boerhaave, professor of anatomy and surgery, when only 20 years old. This office he filled for half a century, and acquired a greater reputation than any of his predecessors. He has left several valuable anatomical works; and particularly very accurate descriptions, and plates of the muscles and bones, which are still highly esteemed.

A'lbor. Urine.

A'lbora. A sort of itch; or rather of leprosy. Paracelsus says, it is a complication of the morphew, serpigo, and leprosy. When cicatrices appear in the face like the serpigo, and then turn to small blisters of the nature of the morphew, it is the albora. It terminates without ulceration, but by fetid evacuations in the mouth and nostrils; it is also seated in the root of the tongue.

Albo'rea. Quicksilver.

A'lbot. A crucible.

Albo'tai. Turpentine.

A'lbotar. Turpentine.

A'lbotat. White lead.

A'lbotim. Turpentine.

A'leotis. A cutaneous phlegmon or boil.

ALBUCA'SIS, an Arabian physician and surgeon, of considerable merit, who lived about the beginning of the twelfth century. He has copied much from preceding writers, but added also many original observations; and his works may be still perused with pleasure. He insisted on the necessity of a surgeon being skilled in anatomy, to enable him to operate with success, as well as acquainted with the materia medica, that he may apply his remedies with propriety. He appears to have extracted polypi from the nose, and performed the operation of bronchotomy. He is the first who left distinct descriptions and delineations of the instruments used in surgery, and of the manner of employing them.

Albugi'nea o'culi. (From *albus*, white.) See *Adnata tunica.*

Albugi'nea te'stis. (*Albuginea*; from *albus*, white; so called on account of its white colour.) *Tunica albuginea testis.* The innermost coat of the testicle. It is a strong, white, and dense membrane, immediately covering the body or substance of the testicle. On its outer surface it is smooth, but rough and uneven on the inner.

Albu'ginous humour. The aqueous humour of the eye.

Albu'go oculo'rum. A white opacity of the cornea of the eye. The Greeks named it *leucoma*; the Latins, *albugo*, *nebula*, and *nubecula*; some ancient writers have called it *pterygium*, *janua oculi*, *onyx*, *unguis*, and *ægides*. It is a variety of Cullen's *Caligo Corneæ.*

Albuhar. White lead.

A'lbum ba'lsamum. The balsam of copaiba.

A'lbum græ'cum. The white dung of dogs. It was formerly applied as a discutient, to the inside of the throat, in quinsies, being first mixed with honey: medicines of this kind have long since justly sunk into disuse.

A'lbum o'lus. Lamb's lettuce, or corn-sallad. The Valeriana locusta of Linnæus.

ALBU'MEN. *Albumine.* Coagulable lymph. Albumen is very abundant in the animal kingdom. It is the principal constituent part of the serum of the blood, and the lymphatic fluid. It forms the cheese in milk, and makes up the greater part of the white of eggs. It is composed of carbon, hydrogen, azot, and oxygen; and sometimes contains phosphorus, and somewhat of calcareous earth.

ALBU′MEN O′VI. *Albugo ovi. Albumen; albor ovi, ovi albus liquor, ovi candidum, albamentum, clareta.* The white of an egg.

A′LCAHEST. An Arabic word to express an universal dissolvent, which was pretended to by Paracelsus and Helmont. Some say that Paracelsus first used this word, and that it is derived from the German words *al* and *geest*, i. e. *all spirit:* and that Van Helmont borrowed the word, and applied it to his invention, which he called the universal dissolvent.

A′LCALI. (Arab.) See *Alkali.*

ALCALIZATION. The impregnating any spirituous fluid with an alkali.

ALCANNA. (Indian word.) See *Anchusa.*

A′LCAOL. The solvent for the preparation of the philosopher's stone.

A′LCEA. (From αλκη, strength.) The name of a genus of plants in the Linnæan system. Class, *Monadelphia.* Order, *Polyandria.* Hollyhock.

A′LCEA ÆGYPTI′ACA VILLO′SA. See *Hibiscus abelmoschus.*

A′LCEA I′NDICA. See *Hibiscus abelmoschus.*

A′LCEA RO′SEA. Common hollyhock. The flowers of this beautiful tree are said to possess adstringent and mucilaginous virtues. They are seldom used medicinally.

A′LCEBAR. See *Lignum Aloes.*

A′LCEBRIS VI′VUM. See *Sulphur vivum.*

A′LCHABRIC. Sulphur vivum.

A′LCHACHIL. Rosemary.

A′LCHARITH. Quicksilver.

A′LCHIEN. This word occurs in the Theatrum Chemicum, and seems to signify that power in nature by which all corruption and generation are effected.

ALCHEMI′LLA. (So called because it was celebrated by the old alchemists.)

1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria.* Order, *Monogynia.* Ladies' mantle.

2. The pharmacopœial name of the plant called ladies' mantle. *Alchemilla vulgaris; foliis lobatis* of Linnæus. It was formerly esteemed as a powerful adstringent in hæmorrhages, fluor albus, &c. given internally.

ALCHEMI′LLA VULGA′RIS. See *Alchemilla.*

ALCHIMELEC. (Heb.) The Egyptian melilot.

A′LCHEMY. *Alchemia. Alchimia. Alkima.* That branch of chemistry which relates to the transmutation of metals into gold; the forming a panacea or universal remedy; an alkahest, or universal menstruum; an universal ferment; and many other absurdities.

A′LCHIBRIC. Sulphur.

ALCHIMI′LLA. See *Alchemilla.*

A′LCHITRON. Oil of Juniper; also the name of a dentifrice of Messue.

A′LCHUTE. See *Morum.*

A′LCHYMY. Alchemy.

A′LCHLYS. A speck on the pupil of the eye, somewhat obscuring vision.

A′LCIMAD. Antimony.

A′LCOB. Sal-ammoniac, or muriat of ammonia.

ALCO′CALUM. (Perhaps Indian.) Artichoke, or cinara.

A′LCOFOL. Antimony.

A′LCOHOL. See *Alkohol.*

A′LCOLA. (Heb.) The aphthæ, or thrush. Paracelsus gives this name to tartar, or excrement of urine, whether it appears as sand, mucilage, &c.

ALCOLI′TA. Urine.

ALCO′NE. Brass.

A′LCOR. Æs ustum.

A′LCTE. It is the name of a plant mentioned by Hippocrates. Foesius thinks it is the elder.

ALCU′BRITH. Sulphur.

ALCYO′NIUM. Bastard sponge, a spongy plant-like substance, which is met with on the sea-shore: it is of different shapes and colours. It is difficult to say what the Greeks called by this name. Dioscorides speaks of five sorts of it. They are calcined with a little salt, as dentifrices, and are used to remove spots on the skin.

Alder-tree. See *Betula Alnus.*

Alder, berry-bearing. See *Rhamnus Frangula.*

ALDER WINE. When well fermented, and having a proper addition of raisins in its composition, is frequently a rich and strong liquor; it keeps better than many of the other made-wines, often for a number of years, and was formerly supposed to possess many medical virtues; but these experience does not seem to sanction: and the virtues of the alder, like those of many other simples formerly prized, have sunk into oblivion.

ALE. *Cerevisia. Liquor cereris. Vinum hordeaceum.* Barley wine. A fermented liquor made from malt and hops, and chiefly distinguished from beer, made from the same ingredients, by the quantity of hops used therein; which is greater in beer, and therefore renders the liquor more bitter, and fitter for keeping. Ale, when well fermented, is a wholesome beverage, and seems only to disagree with those subject to asthma, or any disorder of the respiration, or irregularity in the digestive organs. The old dispensatories enumerate several medicated ales, such as *cerevisia oxydorica,* for the eyes; *cerevisia antiarthritica,* against the gout; *cephalica, epileptica,* &c.

ALEARA. A cucurbit.

ALE′BRIA. (From *alo,* to nourish.) Nourishing foods, or medicines.

A′LEC. *Alech.* Vitriol.

ALE′CHARITH. Mercury.

ALEI′MMA. (From αλειφω, to anoint.) An ointment.

ALEI′ON. (’Αλείον, copious.) Hippocrates uses this word as an epithet for water.

Alei′pha. (From ἀλειφω, to anoint.) Any medicated oil.

Alelai′on. (From αλς, salt, and ελαιον, oil.) Oil beat up with salt, to apply to tumours. Galen frequently used it.

Ale′ma. (From α, priv. and λιμος, hunger.) Meat, food, or any thing that satisfies the appetite.

ALE′MBIC. (Some derive it from the Arabian particle *al*, and αμβιξ, from αμβαινω, to ascend. Avicenna declares it to be Arab.) Moorshead. A chemical utensil made of glass, metal, or earthen-ware, and adapted to receive volatile products from retorts. It consists of a body, to which is fitted a conical head, and out of this head descends laterally a beak to be inserted into the receiver.

Ale′mbroth. A Chaldee word, importing the key of art. Some explained it by *sal mercurii*, or *sal philosophorum & artis*; others say it is named *alembrot* and *sal fusionis*, or *sal fixionis*. *Alembroth desiccatum* is said to be the *sal tartari*; hence this word seems to signify alkaline salt, which opens the bodies of metals by destroying their sulphurs, and promoting their separation from the ores. From analogy, it is supposed to have the same effect in conquering obstructions and attenuating viscid fluids in the human body. A peculiar earth, probably containing a fixed alkali, found in the island of Cyprus, has also this appellation; and a solution of the corrosive sublimate, to which the muriat of ammonia has been added, is called sal alembroth.

Ale′mzadar. Crude sal ammoniac, or muriat of ammonia.

Ale′mzadat. Crude sal ammoniac, or muriat of ammonia.

Alepe′nsis. A species of ash-tree which produces manna.

A′les. (From αλς, salt.) The name of a compound salt.

Aleu′ron. (From αλεω, to grind.) Meal.

Alexander. See *Trallian.*

Alexanders, common. This plant, *Smyrnium olusatrum* of Linnæus, was formerly cultivated for salads. It is now superseded by celery.

Alexanders, round-leaved. *Smyrnium perfoliatum* of Linnæus. The blanched stalks of this species are far preferable to those of common alexanders, and are esteemed as stomachic and nervine.

Alexa′ndria. *Alexandrina.* The bay-tree, or laurel, of Alexandria.

Alexa′ndrium. *Emplastrum viride.* A plaster described by Celsus, made with wax, alum, &c.

Alexica′ca. (From αλεξω, to drive away, and κακον, evil.) *Alexicacum.* An antidote, or amulet, to resist poison.

Alexipha′rmics. (*Alexipharmica*, sc. *medicamenta*, from αλεξω, to expel, and φαρμακον, a poison.) *Antipharmica. Caco-alexiteria.* Medicines supposed to preserve the body against the power of poisons, or to correct or expel those taken. The antients attributed this property to some vegetables, and even waters distilled from them. The term, however, is now disused.

Alexipyre′ticum. (From αλεξω, to drive away, and πυρετος, fever.) A febrifuge. A remedy for fever.

Alexipy′retos. *Alexipyretum.* The same as alexipyreticum.

Ale′xir. An elixir.

Alexite′ria. Preservatives from contagion.

Alexite′rium. (From αλεξω, to expel, and τηρεω, to preserve.) A preservative medicine against poison, or contagion.

Alfa′cta. Distillation.

Alfa′tide. Muriat of ammonia.

Alfa′sra. *Alphesara.* Arabic terms for the vine.

A′lfadas. *Alfides.* Cerusse.

A′lfol. Muriat of ammonia.

A′lfusa. Tutty.

A′lgali. A catheter. Also nitre.

A′lgarah. See *Anchilops.*

A′lgaroth. (So called from Victorius Algaroth, a physician of Verona, and its inventor.) *Algarot, Algarothi. Mercurias vitæ. Pulvis Algarothi.* The antimonial part of the butter of antimony, separated from some of its acid by washing it in water. It is violently emetic in doses of two or three grains, and is preferred by many for making the emetic tartar.

Alge′do. (From αλγος, pain.) A violent pain about the anus, perinæum, testes, urethra, and bladder, arising from the sudden stoppage of a virulent gonorrhœa. A term very seldom used.

Alge′ma. (From αλγεω, to be in pain.) *Algemodes. Algematodes.* Uneasiness, pain of any kind.

Alge′riæ. *Algirie.* Lime.

A′lgeroth. See *Algaroth.*

A′lgibic. Sulphur vivum.

A′lgor. A sudden chillness or rigor. A term met with in Sauvage's and Sagar's Nosology.

Algosarel. The Arabian term for the Daucus sylvestris, or carrot.

Alguada. A white leprous eruption.

Alha′gi. (Arab.) A species of *Hedysarum.* The leaves are hot and pungent, the flowers purgative.

Alha′ndala. An Arabian name for colocynth, or bitter apple.

Alha′sef. (Arab.) *Alhasaf.* A sort of fœtid pustule, called also *Hydroa.*

A′lia squi′lla. (From αλιος, belonging to the sea, and σκιλλα, a shrimp.) A prawn.

A′lica. (From *alo*, to nourish. In general signification, a grain; a sort of food admired by the antients; it is not certain whether it is a grain or a preparation of some kind thereof.

A′lices. (From αλιζω, to sprinkle.) Little red spots in the skin, which precede the eruption of pustules in the small-pox.

Aliena′tio mentis. (From *alieno*, to estrange.) *Delirium.* Estrangement of the mind.

Alifo′rmes mu′sculi. Muscles so called from their supposed resemblance to wings. See *Pterygoideus.*

ALIMENTARY CANAL. Alimentary duct. A name given to the whole of those passages which the food passes through from the mouth to the anus. This duct may be said to be the true characteristic of an animal; there being no animal without it, and whatever has it, being properly ranged under the class of animals. Plants receive their nourishment by the numerous fibres of their roots, but have no common receptacle for digesting the food received, or for carrying off the excrements. But in all, even the lowest degree of animal life, we may observe a stomach, if not also intestines, even where we cannot perceive the least formation of any organs of the senses, unless that common one of feeling, as in oysters.

Alimentary duct. The alimentary canal. The thoracic duct is sometimes so called.

Alimos. Common liquorice.

A′limum. See *Arum.*

Alinde′sis. (Ἀλινδησις, from αλινδεμαι, to be turned about.) A bodily exercise, which seems to be rolling on the ground, or rather in the dust, after being anointed with oil. Hippocrates says it hath nearly the same effect as wrestling.

Alipæ′nos. (From α, neg. and λιπαινω, to be fat.) *Alipænum. Alipantos.* An external remedy, without fat or moisture.

Alipa′sma. (From αλειφω, to anoint.) An ointment rubbed upon the body, to prevent sweating.

Alipe. Remedies for wounds in the cheek, to prevent inflammation.

Alipow. A species of turbith, found near Mount Ceti, in Languedoc. It is a powerful purgative, used instead of senna, but is much more active.

Ali′ptæ. (From αλειφω, to anoint.) Servants who anointed the persons after bathing.

Alisanders. See *Smyrnium.*

ALI′SMA. (From αλς, the sea.) Water-plantain. The name of a genus of plants in the Linnæan system. Class. *Hexandria.* Order, *Polygynia.*

Ali′stelis. (From αλς, the sea.) Muriat of ammonia.

A′litt. *Alith.* Asafœtida.

Alkafi′al. Antimony.

A′lkahest. An imaginary universal menstruum, or solvent. See *Alcahest.*

A′lkahest Glaube′ri. Alkaline salts.

A′lkahat Glaube′ri. An alkali.

A′LKALI. (*Alcali*, in Arabic, signifies burnt; or from *al* and *kali*, i. e. the essence, or the whole of kali, the plant from which it was originally prepared, though now derived from plants of every kind.) *Alcali, alafi, alafor, alafort, calcadis.* A term given to substances which possess the following properties: They are incombustible, and soluble in water: they possess an acrid, urinous taste. They unite with another class of bodies called acids, and form new compounds, in which both the acid and alkaline properties are more or less lost. They render oils miscible with water. They change various blue vegetable pigments to green; red to violet, or blue; and yellow to brown. Blue pigments, that have been turned red with acids, are again restored by alkalis to their primitive colours. They attract water and carbonic acid from the atmosphere. They unite to sulphur by fusion, and by means of water. They exert a great solvent power on the cellular membrane and animal fibre. They also corrode woollen cloth, and, if sufficiently concentrated, convert it into a sort of saponaceous jelly.

There are only three kinds of alkalis at present known:

1. The mineral, called *soda*, in the new chemical nomenclature. See *Soda.*

2. The vegetable, called *potassa*, in the new chemical nomenclature. See *Potassa.*

3. *Ammonia*, or the caustic volatile alkali, is the third. See *Ammonia.*

To these, some chemists add barytes, and some other earths: which, agreeing with alkalis in some respects, are properly called alkaline earths.

Potassa and soda, not being converted to the state of vapour, but by a very intense heat, are termed fixed alkalis: but ammonia, existing in the gaseous form at common temperatures, is distinguished by the name of volatile alkali. The two former, when mixed with siliceous substances, and exposed to a strong heat, form a more or less perfect glass. They emit light on the affusion of the dense acids when freed from water.

ALKALESCENT. Slightly alkaline.

Alkali, caustic. An alkali is so called when deprived of the carbonic acid it usually contains, for it then becomes more caustic, and more violent in its action.

A′lkali fi′xum. Those alkalis are so called, that emit no characteristic smell, and cannot be volatilized, but with the greatest difficulty. Two kinds of fixed alkalis have only hitherto been made known, namely, potash and soda. See *Potassa* and *Soda.*

Alkali, fossile. See *Soda.*

Alkali, mineral. (So called because it forms the basis of marine salts.) See *Soda.*

Alkali, vegetable. (So called because it abounds in many vegetables.) See *Potassa.*

Alkali, volatile. (So called because it is volatile, in opposition to the other alkalis, which are fixed.) See *Ammonia.*

ALKALI′NA. A class of substances described by Cullen as comprehending the substances otherwise termed *antacida.* They consist of alkalis, and other substances which neutralize acids. The principal alkalines in use, are the carbonates and subcarbonates of soda and potash, the subcarbonate of ammonia, lime water, chalk, magnesia and its carbonate.

Alkalization. (*Alkalizatio, onis,* f.) Alkalization. The impregnating any thing with an alkaline salt, as spirit of wine, &c.

A'lkanet. (*Alkanah,* a reed, Arab.) Radix Anchusæ.

Alka'nna. See *Anchusa.*

Alkanna vera. See *Lawsonia.*

Alka'sa. *Alksoal.* A crucible.

Alka'nthum. Arsenic.

A'lkant. Quicksilver.

ALKEKE'NGI. (*Alkekengi,* Arab.) The winter-cherry. See *Physalis.*

Alke'rmes. A term borrowed from the Arabs, denoting a celebrated remedy, of the form and consistence of a confection, whereof the kermes is the basis. See *Kermes.*

Alkerva. (Arab.) Castor oil.

ALKOHOL. (An Arabian word, which signifies antimony: so called from the usage of the Eastern ladies to paint their eye-brows with antimony, reduced to a most subtle powder; whence it at last came to signify any thing exalted to its highest perfection.) *Alcohol. Alkol. Spiritus vinosus rectificatus. Spiritus vini rectificatus. Spiritus vini concentratus. Spiritus vini rectificatissimus.* Alkohol is highly rectified spirit of wine, freed from all those aqueous particles which are not essential to it, by duly performing rectification. In its purest state, it is quite colourless, and clear, of a strong and penetrating smell and taste; capable of being set on fire without a wick, and burning with a flame, without leaving a residue, and without smoke and soot. Alkohol is miscible with water in all proportions. It is not known to freeze in any degree of coldness. It is the direct menstruum or solvent of resins. It dissolves, also, the natural balsams. The resinous and various other parts of plants are also soluble in alkohol; hence it is made use of for extracting those parts, and for making the preparations called *elixirs, tinctures, essences,* &c. In England, alkohol is procured by distillation from molasses; in Scotland and Ireland, from an infusion of malt. This last, before its rectification, is termed *whiskey.* In the East-Indies, *arrack* is distilled from rice; in the West-Indies, *rum* from the sugar-cane; and in France and Spain, *brandy* from wine; all these afford alkohol by distillation. On the human solids, alkohol acts as a most violent corrugator and stimulus.

A'lkosor. Camphire.

A'lki plumbi. Supposed to be acetate of lead.

Alkymia. Powder of basilisk.

Allabor. Lead.

Allantoi'des membra'na. (*Allantoides;* from αλλας, a hog's pudding, and ειδος, likeness; because in some brutal animals, it is long and thick.) A membrane of the fœtus, peculiar to brutes, which contains the urine discharged from the bladder.

Alleluia. (Heb. *Praise the Lord.*) The acetosa, or wood-sorrel; so named from its many virtues. See *Oxalis.*

All-good. *English mercury.* The vulgar name for the *Chenopodium bonus Henricus* of Linnæus; a plant which may be boiled for spinach, and which is in no degree inferior to it. See *Chenopodium.*

All-heal. See *Heraclium* and *Stachys.*

ALLIA'RIA. (From *allium,* garlick; from its smell resembling garlick.) Jack-of-the-hedge. Sauce-alone, or stinking hedge-mustard. See *Erysimum.*

A'llicar. Vinegar.

Alli'coa. Petroleum.

Alligatu'ra. A ligature, or bandage.

Allio'ticum. (From αλλιοω, to alter, or vary.) An alterative medicine, consisting of various antiscorbutics. *Galen.*

ALLIUM. (From *oleo,* to smell, because it stinks; or from αλεω, to avoid, as being unpleasant to most people.) Garlick.

1. The name of a genus of plants in the Linnæan system. Class, *Hexandria.* Order *Monogynia.* Garlick. Four species of this genus are used medicinally.

2. The pharmacopœial name of garlick. See *Allium Sativum.*

A'llium cepa. The Onion. *Cepa. Allium:—scapo nudo infernè ventricoso longiore, foliis teretibus,* of Linnæus. Dr. Cullen says, onions are acrid and stimulating, and possess very little nutriment. With bilious constitutions they generally produce flatulency, thirst, head ache, and febrile symptoms: but where the temperament is phlegmatic, they are of infinite service, by stimulating the habit and promoting the natural secretions, particularly expectoration and urine. They are recommended in scorbutic cases, as possessing antiscorbutic properties. Externally, onions are employed in suppurating poultices, and suppression of urine in children is said to be relieved by applying them, roasted, to the pubes.

A'llium po'rrum. The Leek or Porret. *Porrum. Allium porrum* of Linnæus. Every part of this plant, but more particularly the root, abounds with a peculiar odour. The expressed juice possesses diuretic qualities, and is given in the cure of dropsical diseases, and calculous complaints.

A'llium sati'vum. Garlick. *Allium. Theriaca rusticorum. Allium:—caule planifolio bulbifero, bulbo composito, staminibus tricuspidatis,* of Linnæus. This species of garlick, according to Linnæus, grows spontaneously in Sicily; but, as it is much employed for culinary and medicinal purposes, it has been long very generally cultivated in gardens. Every part of the plant, but more especially the root, has a pungent acrimonious taste, and a peculiarly offensive strong smell. This odour is extremely penetrating and diffusive; for, on the root being taken into the stomach, the alliaceous scent impregnates the whole system, and is discoverable in the various excretions, as in the urine, perspiration, milk, &c. Garlick is generally allied to the onion, from which it seems only to differ in being more powerful in its effects, and in its active matter, being in a more fixed state. By stimulating the stomach, they both favour digestion, and, as a stimulus, are readily diffused over the system. They may, therefore, be considered as useful condiments with the food of phlegmatic people, or those whose circulation is languid, and secretions interrupted; but with those subject to inflammatory complaints, or where great irritability prevails, these roots, in their acrid state, may prove very hurtful. The medicinal uses of garlick are various; it has been long in estimation as an expectorant in pituitous asthmas, and other pulmonary affections, *unattended* with inflammation. In hot bilious constitutions, therefore, garlick is improper: for it frequently produces flatulence, head-ache, thirst, heat, and other inflammatory symptoms. A free use of it is said to promote the piles in habits disposed to this complaint. Its utility as a diuretic in dropsies is attested by unquestionable authorities; and its febrifuge power has not only been experienced in preventing the paroxysms of intermittents, but even in subduing the plague. Bergius says quartans have been cured by it; and he begins by giving one bulb, or clove, morning and evening, adding every day one more, till four or five cloves be taken at a dose; if the fever then vanishes, the dose is to be diminished, and it will be sufficient to take one, or two cloves, twice a-day, for some weeks. Another virtue of garlick is that of an anthelminthic. It has likewise been found of great advantage in scorbutic cases, and in calculous disorders, acting in these, not only as a diuretic, but, in several instances, manifesting a lithontriptic power. That the juice of alliaceous plants, in general, has considerable effects upon human calculi, is to be inferred from the experiments of Lobb; and we are abundantly warranted in asserting that a decoction of the beards of leeks, taken liberally, and its use preserved in for a length of time, has been found remarkably successful in calculous and gravelly complaints. The penetrating and diffusive acrimony of garlick, renders its external application useful in many disorders, as a rubefacient, and more especially as applied to the soles of the feet, to cause a revulsion from the head or breast, as was successfully practised and recommended by Sydenham. As soon as an inflammation appears, the garlick cataplasm should be removed, and one of bread and milk be applied, to obviate excessive pain. Garlick has also been variously employed externally, to tumours and cutaneous diseases; and, in certain cases of deafness, a clove, or small bulb of this root, wrapt in gauze or muslin, and introduced into the meatus auditorius, has been found an efficacious remedy. Garlick may be administered in different forms; swallowing the clove entire, after being dipped in oil, is recommended as the most effectual; where this cannot be done, cutting it into pieces without bruising it, and swallowing these may be found to answer equally well, producing thereby no uneasiness in the fauces. On being beaten up, and formed into pills, the active parts of this medicine soon evaporate: this Dr. Woodville, in his Medical Botany, notices, on the authority of Cullen, who thinks that Lewis has fallen into a gross error, in supposing dried garlick more active than fresh. The syrup and oxymel of garlick, which formerly had a place in the British Pharmacopœias, are now expunged. It may be necessary to notice that, by some, the cloves of garlick are bruised, and applied to the wrists, to cure agues, and to the bend of the arm, to cure the tooth-ache: when held in the hand, they are said to relieve hiccough; when beat with common oil into a poultice, they resolve sluggish humours; and, if laid on the navels of children, they are supposed to destroy worms in the intestines.

A'llium victoria'le. *Victorialis longa.* The root, which when dried loses its alliaceous smell and taste, is said to be efficacious in allaying the abdominal spasms of gravid females.

Allo'choos. (From αλλος, another, and χεω, to pour.) Hippocrates uses this word to mean delirious.

Alloeo'sis. (From αλλος, another.) Alteration in the state of a disease.

Alloeo'tica. (From αλλος, another.) Alteratives. Medicines which change the appearance of the disease.

Allogno'sis. (From αλλος, another, and γινωσκω, to know.) Delirium; perversion of the judgment; incapability of distinguishing persons.

Allo'phasis. (From αλλος, another, and φαω, to speak.) According to Hippocrates, a delirium, where the patient is not able to distinguish one thing from another.

Allotriopha'gia. (From αλλοτριας, foreign, and φαγω, to eat.) A synonym of *pica.* See *Pica.* In Vogel's Nosology it signifies the greedily eating unusual things for food.

ALLOY. By this word, chemists and artificers commonly understand any portion of base metal, or metallic mixture, which is added to lower the more valuable metals, particularly gold and silver; likewise all compounds of metals united by fusion into one seemingly homogeneous mass, unless mercury be present, when they are termed Amalgams.

Allspice. See *Myrtus Pimenta.*

A'lma. Water; and the first motion of a fœtus to free itself from its confinement.

Almabri. A stone-like amber.

A'lmagra. *Bolum cuprum.*

1. Red earth, or ochre, used by the antients as an astringent.

2. Rulandus says it is the same as *Lotio.*

3. In the Theatrum Chymicum, it is a name for the white sulphur of the alchemists.

Almara'nda. *Almakis.* Litharge.

Alma'nda catha'rtica. A plant growing on the shores of Cayenne and Surinam, used by the inhabitants as a remedy for the colic; supposed to be cathartic.

Alma'rcab. (Arab.) Litharge of silver.

Almarca'rida. Litharge of silver.

Alma'rgen. *Almarago.* Coral.

Almarkasi'ta. Mercury.

Alma'rtak. Powder of litharge.

Almata'tica. Copper.

Almeca'site. *Almechasite.* Copper.

Almeaile'tu. A word used by Avicenna, to express a preternatural heat less than that of fever, and which may continue after a fever.

Alme'ne. Sal lucidum, or sal gemmæ.

Almi'sa. Musk.

Almiza'dir. Verdigris, or muriat of ammonia.

Almiza'dar. Muriat of ammonia.

Almond, bitter. See *Amygdalus.*

Almond, common. See *Amygdalus.*

Almond, sweet. See *Amygdalus.*

Almonds of the ears. A popular name for the tonsils, which have been so called from their resemblance to an almond in shape. See *Tonsils.*

Almonds of the throat. A vulgar name for the tonsils.

Alnabati. In Avicenna and Serapion, this word means the *siliquadulcis,* a gentle laxative.

A'lnec. Stannum, or tin.

A'lneric. Sulphur vivum.

A'LNUS. (*Alno,* Ital.) The alder.

The pharmacopœial name of two plants, sometimes used in medicine, though rarely employed in the present practice.

1. *Alnus rotundifolia; glutinosa; viridis;* the common alder-tree. See *Betula.*

2. *Alnus nigra,* vel *frangula;* the black, or berry-bearing alder. See *Rhamnus Frangula.*

A'LOË. (From *ahlah,* a Hebrew word, signifying growing near the sea.) The Aloe.

A genus of plants of the Linnæan system. Class, *Hexandria.* Order, *Monogynia.*

Aloë Caballina. See *Aloës.*

Aloë Guinensis. See *Aloës.*

Aloë perfoliata. See *Aloës.*

Aloë Socotorina. See *Aloës.*

Aloë Zocotorina. See *Aloës.*

ALOES. (*Aloë, es,* f.) *Fel naturæ.* The inspissated juice of the aloe plant. Aloes are distinguished into three species, *socotorine, hepatic,* and *caballine;* of which the two first are directed for officinal use in our pharmacopœias.

The 1st. *Aloë Succotorina. Aloë Zoctorinia.* Succotorine aloes, is obtained from a variety of the *Aloë perfoliata* of Linnæus:—*foliis caulinis dentatis, amplexicaulibus vaginantibus, floribus corymbosis, cernuis, pedunculatis subcylindricis:* it is brought over wrapt in skins, from the Island of Socotora, in the Indian Ocean; it is of a bright surface and in some degree pellucid; in the lump, of a yellowish red colour, with a purplish cast; when reduced into powder, it is of a golden colour. It is hard and friable in very cold weather; but in summer it softens very easily betwixt the fingers. It is extremely bitter, and also accompanied with an aromatic flavour, but not so much as to cover its disagreeable taste. Its scent is rather agreeable, being somewhat similar to that of myrrh. Of late this sort has been very scarce, and its place in a great measure supplied by another variety, brought from the Cape of Good Hope; which is said to be obtained from the Aloë Spicata of Linnæus, by inspissating the expressed juice of the leaves, whence it is termed in the London Pharmacopœia Aloës Spicatæ Extractum.

2. *Aloë hepatica, vel Barbadensis:* the common or Barbadoes or hepatic aloes. This was thought to come from a variety of the *Aloë perfoliata* of Linnæus:—*floribus pedunculatis, cernuis corymbosis, subcylindricis, foliis spinosis, confertis, dentatis, vaginantibus, planis, maculatis:* but Dr. Smith has announced, that it will be shewn, in Sibthorp's Flora Græca, to be from a distinct species, the Aloë vulgaris, or true αλοη, of Dioscorides; and it is therefore termed in the London Pharmacopæia Aloës vulgaris Extractum. The best is brought from Barbadoes in large gourd-shells; an inferior sort in pots, and the worst in casks. It is darker coloured than the socotorine, and not so bright; it is also drier and more compact, though sometimes the sort in casks is soft and clammy. To the taste it is intensely bitter and nauseous, being almost wholly without that aroma which is observed in the socotorine. To the smell it is strong and disagreeable.

3. *Aloë caballina vel Guineensis;* Horse-aloes. This is easily distinguished from both the foregoing by its strong rank smell; in other respects it agrees pretty much with the hepatic, and is now not unfrequently sold in its place. Sometimes it is prepared so pure and bright as scarcely to be distinguishable by the eye, even from the socotorine, but its offensive smell betrays it; and if this also should be dissipated by art, its wanting the aromatic flavour of the finer aloes will be a sufficient criterion. This aloe is not admitted into the materia medica, and is employed chiefly by farriers.

The general nature of these three kinds is nearly the same. Their particular differences only consist in the different proportions of gum to their resin, and in their flavour. The smell and taste reside principally in the gum, as do the principal virtues of the aloes. Twelve ounces of Barbadoes aloes yields nearly 4 ounces of resin, and 8 of gummy extract. The same quantity of socotorine aloes yields 3 ounces of resin and 9 of gummy extract.

Aloes is a well known stimulating purgative, a property which it possesses not only when taken internally, but also by external application. The cathartic quality of aloes does not reside in the resinous part of the drug, but in the gum, for the pure resin has little or no purgative power. Its medium dose is from 5 to 15 grains, nor does a larger quantity operate more effectually. Its operation is exerted on the large intestines, principally on the rectum. In small doses long continued, it often produces much heat, and irritation, particularly about the anus, from which it sometimes occasions a bloody discharge; therefore, to those who were subject to piles, or of an hæmorrhagic diathesis, or even in a state of pregnancy, its exhibition has been productive of considerable mischief; but on the contrary, by those of a phlegmatic constitution, or those suffering from uterine obstructions, (for the stimulant action of aloes, it has been supposed, may be extended to the uterus), and in some cases of dyspepsia, palsy, gout, and worms, aloes may be employed as a laxative with peculiar advantage. In all diseases of the bilious tribe, aloes is the strongest purge, and the best preparations for this purpose are the pilula ex aloë cum myrrhâ, the tinctura aloës, or the extractum colocynthidis compositum. Its efficacy in jaundice is very considerable, as it proves a succedaneum to the bile, of which in that disease there is a defective supply to the intestine either in quantity or quality. Aloes therefore may be considered as injurious where inflammation or irritation exist in the bowels or neighbouring parts, in pregnancy, or in habits disposed to piles; but highly serviceable in all hypochondriac affections, cachectic habits, and persons labouring under oppression of the stomach caused by irregularity. Aromatics correct the offensive qualities of aloes the most perfectly. The canella alba answers tolerably, and without any inconvenience; but some rather prefer the essential oils for this purpose. Dr. Cullen says, "If any medicine be entitled to the appellation of a *stomach purge*, it is certainly aloes. It is remarkable with regard to it, that it operates almost to as good a purpose in a small as in a large dose; that one or two grains will produce one considerable dejection, and 20 grains will do no more, except it be that in the last dose the operation will be attended with gripes, &c. Its chief use is to render the peristaltic motion regular, and it is one of the best cures in habitual costiveness. There is a difficulty we meet with in the exhibition of purgatives, viz. that they will not act but in their full dose, and will not produce half their effect if given in half the dose. For this purpose we are chiefly confined to aloes. Neutral salts in half their dose will not have half their effect; although even from these, by large dilution, we may obtain this property; but besides them and our present medicine, I know no other which has any title to it, except sulphur. Aloes sometimes cannot be employed. It has the effect of stimulating the rectum more than other purges, and with justice has been accused of exciting hæmorrhoidal swellings, so that we ought to abstain from it in such cases, except when we want to promote them. Aloes has the effect of rarifying the blood and disposing to hæmorrhagy, and hence it is not recommended in uterine fluxes. Fœtid gums are of the same nature in producing hæmorrhagy, and perhaps this is the foundation of their emmenagogue power." Aloes is administered either simply in powders, which is too nauseous, or else in composition: — 1. With purgatives, as soap, scammony, colocynth, or rhubarb. 2. With aromatics, as canella, ginger, or essential oils. 3. With bitters, as gentian. 4. With emmenagogues, as iron, myrrh, wine, &c. It may be exhibited in pills as the most convenient form, or else dissolved in wine, or diluted alkohol. The officinal preparations of aloes are the following; — Pilulæ Aloës. Pilula Aloës Composita. Pilulæ Aloës cum Assafœtidâ. Pilula Aloes cum Colocynthide. Pilula Aloes cum Myrrh. Tinctura Aloës, Tinctura Aloes Ætherialis. Tinctura Aloes et Myrrh. Vinum Aloës. Extractum Aloës. Decoctum Aloës Compositum. Pulv. Aloës comp. Pulv. Aloës cum Canell. Pulv. Aloës cum Guaiac. Tinctura Aloës comp. Ext. Colocynth. comp. Tinctura Benzoin. comp. and some others.

Aloeda'ria. (From αλοη, the aloe.) Compound purging medicines, so called from having aloes as the chief ingredient.

Aloephangina. Medicines formed by a combination of aloes and aromatics.

A'loes See *Aloë*.

A'loes spica'tæ extra'ctum. See *Aloë*.

A'loes vulga'ris extra'ctum. See *Aloë*.

Aloetics. Medicines wherein aloes is the chief or fundamental ingredient.

Alogotro'phia. (From αλογος, disproportionate, and τρεφω, to nourish.) Unequal nourishment, as in the rickets.

A'lohar. (Arab.) *Alohoc.* Mercury.

A'loes li'gnum. See *Lignum Aloes.*

Alo'mba. (Arab.) *Alooc.* Plumbum, or lead.

Alo'peces. (From αλωπηξ, the fox.) The psoæ muscles are so called by Fallopius and Vesalius, because in the fox they are particularly strong.

Alopecia. (From αλωπηξ, a fox; because the fox is subject to a distemper that resembles it: or, as some say, because the fox's urine will occasion baldness.) *Athrix depilis. Phalacrotis.* Baldness, or the falling off of the hair; when on the sinciput, *calvities, calvitium.*

Alosa. (From αλισκω, to take; because it is a ravenous fish.) The Shad. See Clupea.

A'losat. *Alosohoc.* Quicksilver.

Alosa'nthi. (From αλς, salt, and ανθος, a flower.) *Alosanthum.* Flowers of salt.

Alphabetum chy'micum. Raymond Lully hath given the world this alphabet, but to what end is difficult to say:

A *significat Deum.*
B ——— *Mercurium.*
C ——— *Salis Petram.*
D ——— *Vitriolum.*
E ——— *Menstruale.*
F ——— *Lunam claram.*
G ——— *Mercurium nostrum.*
H ——— *Salem purum.*
I ——— *Compositum Lunæ.*
K ——— *Compositum Solis.*
L ——— *Terram compositi Lunæ.*
M ——— *Aquam compositi Lunæ.*
N ——— *Ærem compositi Lunæ.*
O ——— *Terram compositi Solis.*
P ——— *Aquam compositi Solis.*
Q ——— *Ærem compositi Solis.*
R ——— *Ignem compositi Solis.*
S ——— *Lapidem Album.*
T ——— *Medicinam corporis rubei.*
U ——— *Calorem fumi secreti.*
X ——— *Ignem siccum cineris.*
Y ——— *Calorem balnei.*
Z ——— *Separationem liquorum.*
Z ——— *Alembicum cum cucurbitâ.*

A'lphanic. *Alphenic.* An Arabian word (signifying tender) for barley-sugar, or sugar-candy.

A'lphita. (*Alphita*, the plural of ἀλφιτον, the meal of barley in general.) By Hippocrates this term is applied to barley-meal either toasted or fried. Galen says that κριμνα is coarse meal, αλευρον is fine meal, and αλφιτα is a middling sort.

Alphi'tidon. *Alphitidum.* It is when a bone is broken into small fragments like *Alphita*, i. e. bran.

Alpho'nsin. The name of an instrument for extracting balls. It is so called from the name of its inventor Alphonso Ferrier, a Neapolitan physician. It consists of three branches, which separate from each other by their elasticity, but are capable of being closed by means of a tube in which they are included.

A'lphus. (αλφος, from αλφαινω, to change; because it changes the colour of the skin.) *Vitiligo alba. Morphæa alba. Lepra maculosa alba.* A species of leprosy, called by the ancients *vitiligo*, and which they divided into *alphus, melas,* and *leuce.* It is produced by a peculiar miasma, which is endemial to Arabia. See *Lepra.*

A'lpini ba'lsamum. Balm of Gilead.

ALPI'NUS, Prosper, a Venetian, born in 1553, celebrated for his skill in medicine and botany. After graduating at Padua, he went to Egypt, and during three years carefully studied the plants of that country, and the modes of treating diseases there; of which he afterwards published a very learned account. He has left also some other less important works. He was appointed physician to the celebrated Andrew Doria; and subsequently botanical professor at Padua, which office he retained till his death in 1616.

A'lrachas. Lead.

Alra'tica. A word used by Albucasis, to signify a partial or a total imperforation of the vagina. It is an Arabic word.

Alsa'mach. An Arabic name for the great hole in the os petrosum.

A'LSINE. (From αλσος, a grove; so called because it grows in great abundance in woods and shady places.) The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Trigynia.* Chickweed.

A'lsine me'dia. *Morsus gallinæ centunculus.* The name for the plant, called chickweed, which, if boiled tender, may be eaten like spinach, and forms also an excellent emollient poultice.

ALSTON, Charles, born in Scotland in 1683, was early attached to the study of botany, and distinguished himself by opposing the sexual system of Linnæus. He afterwards studied under Boerhaave at Leyden; then returning to his native country, was materially instrumental, in conjunction with the celebrated Alexander Monro, in establishing the medical school at Edinburgh, where he was appointed professor of botany and materia medica. He died in 1760. His "Lectures on the Materia Medica," a posthumous work, abound in curious and useful facts, which will long preserve their reputation.

A'ltafor. Camphire.

A'LTERATIVES. (*Alterantia, sc. medicamenta:* from *altero*, to change.) Those remedies are so called, which are given with a view to re-establish the healthy functions of the animal œconomy, without producing any sensible evacuation.

ALTHÆ'A. (From αλθεω, to heal; so called from its supposed qualities in healing.) Marsh-mallow.

1. The name of a genus of plants of the Linnæan system. Class, *Monadelphia.* Order, *Polyandria.*

2. The pharmacopœial name of the marshmallow. See *Althæa Officinalis.*

Althæ'a officinalis. The systematic name of the marsh-mallow. *Althæa:— foliis simplicibus tomentosis.* The leaves and root are generally selected for use. The mucilaginous matter with which this plant abounds, is the medicinal part of the plant; it is commonly employed for its emollient and demulcent qualities in tickling coughs, hoarseness, and catarrhs, in dysentery, and difficulty and heat of urine. It relaxes the passages in nephritic complaints, in which last case a decoction is the best preparation. Two or three ounces of the fresh roots may be boiled in a sufficient quantity of water to a quart, to which one ounce of gum-arabic may be added. The following is given where it is required that large quantities should be used. An ounce of the dried roots is to be boiled in water enough to leave two or three pints to be poured off for use: if more of the root be used, the liquor will be disagreeably slimy. If sweetened, by adding a little more of the root of liquorice, it will be very palatable. The root had formerly a place in many of the compounds in the pharmacopœias, but now it is only directed in the form of syrup.

Altha′naca. *Althanacha.* Orpiment.

Althebe′gium. An Arabian name for a sort of swelling, such as is observed in cachectic and leuco-phlegmatic habits.

Althe′xis. (From αλθειν, to cure, or heal.) Hippocrates often uses this word to signify the cure of a distemper.

Altihit. So Avicenna calls the *Laserpitium* of the ancients.

A′lud. (Arab.) Aloes.

Aludels. Hollow spheres of stone, glass, or earthenware, with a short neck projecting at each end, by means of which one globe might be set upon the other. The uppermost has no opening at the top. They were used in former times for the sublimation of several substances.

Alum. See *Alumen.*

ALU′MEN. (*Alum.* Arab.) *Assos, azub, aseb, elanula. Sulphas aluminæ acidulus cum potassâ. Super-sulphas aluminæ et potassæ. Argilla vitriolata.* Alum.

A salt formed by the combination of the earth called *alumine*, or pure clay, with sulphuric acid, and a little potash, or ammonia.

The alum of commerce, and that presented for medicinal purposes, is afforded by ores which are dug out of the earth for this purpose, and manufactured by first decomposing the ore, then lixiviating it, evaporating the lixivium, and then crystallizing the alum, which affects the form of tetrahedral pyramids, applied to each other base to base; sometimes the angles are truncated.

The following kinds of alum are met with in the shops:

1. Ice or rock alum. *Alumen commune: alumen crystallinum, rupeum, factitium.* Common alum; fictitious alum; English alum. This is always in very large transparent masses, and derives its name from Rocca in Syria, now called Edessa, in which the earliest manufactory of this salt was established: or from the hardness and size of the masses. This species is not very pure.

2. Roman alum. *Alumen Romanum: alumen rubrum, rutilum, rochi Gallis.* Called roch alum by the French. This species, which is prepared in the territory of Civita-Vecchia, comes in lumps of the size of eggs, covered with a reddish efflorescence.

Alum, when first tasted, imparts a sweetness, but is soon felt to be strongly astringent; on account of which virtue it is of very extensive use in medicine and surgery.

Internally it is used as a powerful astringent in cases of passive hæmorrhages from the womb, intestines, nose, and sometimes lungs. In bleedings of an active nature, i. e. attended with fever, and a plethoric state of the system, it is highly improper. Dr. Percival recommends it in the *colica pictonum* and other chronic disorders of the bowels, attended with obstinate constipation. See Percival's Essays. The dose advised in these cases, is from 5 to 20 grains, to be repeated every four, eight, or twelve hours. When duly persisted in, this remedy proves gently laxative, and mitigates the pain.

Alum is also powerfully tonic, and is given with this view in the dose of 10 grains made into a bolus three times a day, in such cases as require powerful tonic and astringent remedies. Another mode of administering it, is in the form of whey made by boiling a drachm of powdered alum in a pint of milk, for a few minutes, and to be taken in the quantity of a tea-cup full three times a day. Dr. Cullen thinks it ought to be employed with other astringents in diarrhœas. In active hæmorrhagies, as was observed, it is not useful, though a powerful medicine in those which are passive. It should be given in small doses, and gradually increased. It has been tried in the diabetes without success; though, joined with nutmeg, it has been more successful in intermittents, given in a large dose, an hour or a little longer, before the approach of the paroxysm. In gargles, in relaxation of the uvula, and other swellings of the mucous membrane of the fauces, divested of acute inflammation, it has been used with advantage; also in every state of the cynanche tonsillaris. Externally alum is much employed by surgeons as a lotion for the eyes, and is said to be preferable to sulphate of zinc or superacetate of lead in the ophthalmia membranarum. From two to five grains dissolved in an ounce of rose water, forms a proper collyrium. It is also applied as a styptic to bleeding vessels, and to ulcers, where there is too copious a secretion of pus. It has proved successful in inflammation of the eyes, in the form of cataplasm, which is made by stirring or shaking a lump of alum in the whites of two eggs, till they form a coagulum, which is applied to the eye, between two pieces of thin linen rag. This substance is also employed in the form of injection in cases of gleet or fluor albus.

When deprived of its humidity, by placing it in an earthen pan over a gentle fire, till it ceases to bubble, it is termed burnt alum, *alumen exsiccatum*, and is sometimes employed by surgeons to destroy fungous flesh, and is a principal ingredient in most styptic powders. Alum is also applied to many purposes of life; in this country, bakers mix a quantity with the bread, to render it white; this mixture makes the bread better adapted for weak and relaxed bowels; but in opposite states of the alimentary canal, this practice is highly pernicious. The officinal preparations of alum are: Alumen exsiccatum. Solutio sulphat. cupri ammon. Edin. Liq. alum. comp. Lond. Pulv. sulph. alum. comp. E.

Alu'men ca'tinum. A name of potash.

Alu'men exsicca'tum. See *Alumen*.

Alu'men rutilum.
Alu'men commune.
Alu'men crystallinum.
Alu'men rupeum.
Alu'men factitium.
Alu'men romanum.
Alu'men rubrum.
Alu'men ustum.
See *Alumen*.

ALU'MINE. *Alumina.* Earth of alum. Pure clay.

Aluminous earth derives its name from alum, of which it forms the base. It constitutes the greater part of clay, which forms the lower strata of mountains and plains. It arrests the waters, and causes them to rise in springs to the surface of the earth. Alumina enters into the natural composition of the schistus, and all those stones and earths called argillaceous, such as *potter's-clay*, *fuller's-earth*, *lepidolite*, *mica*, *corundum*, &c. Hitherto it has not been found pure any where, except in the garden of the public schools at Halle in Germany.

Properties of pure Alumine. — Alumine is white, and soft to the touch. It is insipid, adheres to the tongue, and occasions a sense of dryness in the mouth. When moistened with a small quantity of water, it forms a tenaceous, ductile, kneadable paste. When heated to redness, it shrinks considerably in bulk, and at last becomes so hard as to strike fire with flint. After being ignited, it is no longer capable of being kneaded with water into a ductile mass. It recovers, however, this property by solution in an acid and precipitation. Alkalies dissolve it in the humid way, and form compounds decomposable by acids. It dissolves slowly in all acids. It possesses a powerful attraction for lime. The most intense heat of our furnaces is not able to melt it, but it becomes fusible when lime is added. Lavoisier has proved that it is capable of entering into a kind of fusion like paste, by the action of oxygen gas; it then cuts glass and resists the file. It absorbs water and carbonic acid from the atmosphere. By its mixture with water and silex it acquires great solidity. It does not unite with any combustible substance, but becomes fused into coloured frits with metallic oxids. Its specific gravity is 2. It is employed in a multitude of arts.

Method of obtaining pure alumine. — Take any quantity of alum of commerce, dissolve it in six parts of boiling distilled water, and add to this solution, when cold, liquid ammonia, till no further precipitate ensues. Then heat the whole nearly to the boiling point for a few minutes, and transfer it on a filter. In proportion as the fluid passes off, pour more water over the precipitate, until it passes tasteless. Let the precipitate obtained, while yet in a pasty state, be transferred into a glass or Wedgwood's bason, and add to it muriatic acid in small quantities at a time, until the whole is dissolved. Then evaporate the solution, till a drop of it, when suffered to cool on a plate of glass, yields minute crystals: on letting it now cool, crystals of alum will be deposited. Remove these crystals by decanting the fluid, and renew the evaporation, until, on further cooling, no more crystals are formed. Nothing now but pure alumine remains in the solution; the fluid may therefore be decomposed by adding to it gradually liquid ammonia till no further precipitate ensues. The precipitate thus obtained, when well washed and dried, is pure alumine.

The process recommended in general by systematic writers, for obtaining alumine differs from this; it consists in decomposing a solution of alum of commerce by an excess of carbonated alkali, washing the obtained precipitate, and exposing it to a sufficient heat to drive off the carbonic acid. This method however is imperfect, for if the alumine thus obtained be heated with charcoal, and a diluted acid is added to the mixture sulphureted hydrogen gas will be liberated. It adheres to the tongue, and emits a peculiar odour when breathed upon. Sure signs that it is not pure.

It must be obvious that alumine cannot be obtained absolutely pure in this manner. For alum is a triple compound, consisting of alumine, potash, and sulphuric acid in excess. When this excess of acid is saturated, by adding to the solution an alkali, or even pure alumine, a highly insoluble salt (sulphate of alumine) is produced, differing from alum only in the proportion of its base. When we therefore gradually add to a solution of alum, a carbonated alkali, the first effect of the alkali is, to saturate the excess of the sulphuric acid, and the precipitate consists principally of the salt which is insoluble in water. A further quantity of the alkali effects instantly a decomposition of part of the salt, which, in proportion as it takes place, becomes mixed with the alumine; and it is thus covered from the further action of the alkali. This being the case, it is obvious that no subsequent washing can do more than separate the sulphate of potash, and therefore the residuum, instead of being pure alumine, contains also a variable proportion of true sulphate of alumine; the sulphuric acid of which becoming decomposed on heating it in contact with charcoal, accounts for the sulphuretted hydrogen gas produced by the affusion of an acid. With the acids it is known to form more than twenty species of neutral salts. Of these only one is used in medicine and surgery, called *alum*, or *aluminous sulphate*. See *Alumen*.

Alu'minous waters. Waters' impregnated with particles of alum.

Alusar. Manna.

ALVEA'RIUM. (From *alveare*, a beehive.) That part of the meatus auditorius externus is so called, which contains the wax of the ear.

ALVE'OLI. (Plural of *alveolus*, a diminutive of *alveus*, a cavity.) *Botrion, bothrion; frena, mortariolum.* The sockets of the teeth.

A'LVEUS COMMU'NIS. The common duct, or communication of the ampullæ of the membranaceous semicircular canals in the internal ear, is so termed by Scarpa.

A'lveus ampulle'scens. Part of the duct conveying the chyle to the subclavian vein.

Alvidu'ca. (From *alvus*, the belly, and *duco*, to draw.) Purging medicines.

Alviflu'xus. (From *alvus*, and *fluo*, to flow.) A diarrhœa, or purging.

A'LVUS. (*Alvus*, i. f. and sometimes, m. *ab alluendo, quâ sordes alluuntur.*) The belly, stomach and entrails.

A'lyce. (From αλυω, to be anxious.) That anxiety which is attendant on low fevers.

Aly'pia. (From α, neg. and λυπη, pain.) A gentle purgation of the humours without pain.

Aly'pias. *Alypum.* A species of spurge, so called because it purges gently and without pain.

Aly'smus. (From αλυω, to be restless.) Restlessness.

Aly'ssum. (From α, neg and λυσσα, the bite of a mad dog: so called because it was foolishly thought to be a specific in the cure of the bite of a mad dog.) Mad-wort. See *Marrubium*.

Aly'ssum Gale'ni. See *marrubium verticillatum*.

Aly'ssum Pli'nii. See *Galium album*.

Aly'ssum verticilla'tum. The *marrubium verticillatum*.

Alze'mafor. Cinnabar.

A'lzum. *Aldum. Aldrum.* The name of the tree which produces gum bdellium according to some ancient authors.

A'ma. (αμα, together.) A word used in composition.

AMA'LGAM. (From αμα, and γαμειν, to marry.) A substance produced by mixing mercury with a metal, the two being thereby incorporated.

Amame'lis. (From αμα, and μηλεα, an apple.) The bastard medlar of Hippocrates.

Amani'tæ. (From α, priv. and μανια, madness; so called, because they are eatable and not poisonous, like some others.) A tribe of fungous productions, called mushrooms, truffles, and morells, and by the French, champignons.

AMA'RA. (*Amara*, sc. *medicamenta*; from *amarus*, bitter.) Bitters.

The principal bitters used medicinally are: the pure bitters, *gentiana lutea; humulus lupulus*; and *quassia amara*: styptic bitters, *cinchona officinalis; croton cascarilla; quassia simarouba*: and aromatic bitters, *artemisia absinthium; anthemis nobilis; hyssopus*. &c.

Ama'ra dul'cis. See *Solanum Dulcamara*.

Ama'racus. (From α, neg. and μαραινω, to decay; because it keeps its virtues a long time.) Marjoram.

A'maranth e'sculent. See *Amaranthus Oleraceus*.

AMARA'NTHUS. (From α, neg. and μαραινω, to decay.) The name of a genus of plants in the Linnæan system.

Amara'nthus olera'ceus. *Esculent Amaranth.* The leaves of this, and several other species are eaten in India the same as cabbage is here.

Amato'ria febris. (From *amo*, to love.) See *Chlorosis*.

Amato'ria venefi'cia. (From *amo*, to love, and *veneficium*, witchcraft.) Philters. Love powders.

Amato'rii. (*Amatorii*, sc *musculi.*) A term given to the muscles of the eye, by which that organ is moved in ogling.

Amatzqui'tl. (Indian.) See *Arbutus Unedo*.

AMAURO'SIS. (Αμαυρωσις: from αμαυροω, to darken or obscure.) *Gutta serena. Amblyopia.* A genus of disease in the class *locales*, and order *dysæsthesiæ* of Cullen. It arises generally from compression of the optic nerves; *amaurosis compressionis*; from debility, *amaurosis atonica*; from spasm, *amaurosis spasmodica*; or from poisons, *amaurosis venenata*.

This is a disease of the eye attended with a diminution or total loss of sight, without any visible injury to the organ, and arising from a paralytic affection of the retina and optic nerve.

The symptoms of gutta serena are noted for being very irregular. In many cases, the pupil is very much dilated, immoveable and of its natural black colour. Sometimes, however, in the most complete and incurable cases, the pupil is of its natural size, and the iris capable of free motion. In some cases, the pupil has a dull, glassy or horny appearance. Sometimes its colour is greenish, occasionally whitish and opake, so as to be liable to be mistaken for an incipient cataract. Richter mentions a degree of strabismus, as the only symptom, except the loss of sight, as invariably attendant on amaurosis.

The blindness produced by the gutta serena, is generally preceded by an imaginary appearance of numerous insects, or substances, like cobwebs, interposing themselves between objects and the eye. The origin of a cataract on the other hand, is usually attended with a simple cloudiness of vision.

Violent contusions of the head, apoplectic fits, flashes of lightning, frequent exposure to the rays of the sun, severe exercise, strong passions, drunkenness, and other causes of paralytic affections, are enumerated as producing this complaint. Sometimes tumours within the cranium, bony projections, &c. have been found compressing the optic nerves: but in many instances no morbid appearance could be traced, whence the defect has been concluded to exist in these.

The disorder is generally difficult to be removed: but is sometimes much benefited by general and local stimulants, persevered in for a considerable time. If there are marks of congestion in the head, local bleeding, active purging and other evacuations would be proper in the first instance. Blisters and issues behind the ear or neck should also be tried. Richter speaks of much success from the use of medicines acting steadily on the bowels, after premising an emetic. Mr. Ware observes, that in some cases the pupil is contracted, indicating probably, internal inflammation; and then the internal use of mercury, especially the oxymuriate, will be most beneficial. Electricity has been sometimes serviceable, taking the aura or sparks, or even gentle shocks; but galvanism is certainly preferable. Errhines are often useful, as the compound powder of asarabacca; Mr. Ware particularly recommends the hydrargyrus vitriolatus of the former London Pharmacopœia. Stimulants have been sometimes usefully applied to the eye itself, as the vapour of oil of turpentine, an infusion of capsicum, &c. Where the intention of a blister is to stimulate, it is best applied to the temple on the affected side.

Amber seed. See *Hibiscus abelmoschus.*

A'MBE. (Αμϐη, the edge of a rock; from αμϐαινω, to ascend.) An old chirurgical machine for reducing dislocations of the shoulder, and so called, because its extremity projects like the prominence of a rock. Its invention is imputed to Hippocrates. The ambe is the most ancient mechanical contrivance for the above purpose. but is not at present employed.

A'mbela. (Arab.) The cornered hazlenut, the bark of which is purgative.

AMBER. *Succinum.* A beautiful bituminous substance, of a yellow or brown colour, either transparent or opake, which takes a good polish, and, after a slight rubbing, becomes so electric, as to attract straws and small bodies; it was called ηλεκτρον (*electrum*) by the antients, and hence the word electricity. When powdered, it emits an agreeable smell. It is dug out of the earth at various depths, and often contains insects in high preservation; a circumstance which proves that it has been liquid. Amber is also found floating on the shores of the Baltic, and is met with in Italy, Sicily, Poland, Sweden, &c. From its colour or opacity it has been variously distinguished; thus white, orange, golden, cloudy amber, &c. An oil is obtained from it, which, as well as its other preparations is occasionally used in medicine against spasmodic diseases. See *Oleum Succini,* and *Succinic Acid.*

AMBERGRIS. (*Ambragrisea.*) A concrete, bituminous substance, of a soft and tenacious consistence, marked with black, and yellow spots, and of an agreeable and strong smell when heated or rubbed. It is found in very irregular masses, floating on the sea near the Molucca islands, Madagascar, Sumatra, on the coast of Coromandel, Brazil, America, China, and Japan. Several American fishermen assured Dr. Schwediaur, that they often found this substance, either among the excrements of the *Physeter macrocephalus*, a species of whale, or in its stomach, or in a vessel near the stomach. The medical qualities of ambergris are stomachic, cordial, and antispasmodic. It is very seldom used in this country.

Amblo'sis. (Αμϐλωσις: from αμϐλοω, to cause abortion.) A miscarriage.

Amblo'tica. (*Amblotica,* sc. *medicamenta,* αμϐλωτικα; from αμϐλοω, to cause abortion.) Medicines which were supposed to occasion abortion.

Amblyo'pia. (From αμϐλυς, dull, and ωψ, the eye.) Hippocrates means by this word, dimness of sight to which old people are subject. Paulus Actuarius, and the best modern writers, seem to think that amblyopia means the same thing as the incomplete amaurosis. See *Gutta serena* and *Amaurosis.*

Amblyo'smus. *Amblytes.* The same.

A'mbo. (Indian.) The mango.

A'mbon. (From σμϐαινω, to ascend.) Celsus uses this term to signify the margin or tip of the sockets in which the heads of the large bones are lodged.

A'mbone, The same as ambe.

A'mbra. Amber. Also an aromatic gum.

A'mbra cinera'cea. (From *cineraceus,* of the colour of ashes.) Ambergris and grey amber.

A'mbra gri'sea. Ambergris.

A'mbram. Amber.

Ambre'tte. See *Hibiscus abelmoschus.*

Ambulati'va. (From *ambulo,* to walk.)

A species of herpes; so called because it walks or creeps as it were about the body.

A'MBULO. (From αμβαλλω, to cast forth.) *Flatus Furiosus.* A periodical flatulent disease, caused, according to Michaelis, by vapours shooting through various parts of the body.

AMBU'STIO. (From *amburo*, to burn.) *Ambustum.* A burn or scald.

AME'LLA. The same as achmella.

AMENORRHŒA. (From α, priv. μην, a month, and ῥεω, to flow.) A partial or total obstruction of the menses in women from other causes than pregnancy and old age. That this excrementitious discharge should be regular as to quantity and quality, and that it should observe the monthly period, is essential to health. When it is obstructed, nature makes her efforts to obtain for it some other outlet. When these efforts of nature fail, the consequence may be, pyrexia, pulmonic diseases, spasmodic affections, hysteria, epilepsia, mania, apoplexia, chlorosis, according to the general habit and disposition of the patient. Dr. Cullen places this genus in the class *locales*, and order *epischeses.* His species are, 1. *Emansio mensium*; that is, when the menses do not appear so early as is usually expected. See *Chlorosis.* 2. *Suppressio mensium*, when, after the menses appearing and continuing as usual for some time, they cease without pregnancy occurring. 3. *Amenorrhœa difficilis, vel Menorrhagia difficilis*, when this flux is too small in quantity, and attended with great pain, &c.

The causes of a suppression of the menses appear mostly to operate by inducing a constriction of the extreme vessels; such as cold, fear, and other depressing passions, an indolent life, the abuse of acids, &c. It is sometimes symptomatic of other diseases, in which considerable debility occurs, as phthisis pulmonalis. When the discharge has been some time interrupted, particularly in persons previously healthy, hæmorrhages will often happen from other outlets, the nose, stomach, lungs, &c. even in some instances a periodical discharge of blood from an ulcer has occurred. The patient generally becomes obstinately costive, often dyspeptic; colicky pains, and various hysterical symptoms likewise are apt to attend. The means of chief efficacy in restoring the uterine function are those calculated to relax spasm, assisted sometimes by such as increase arterial action, particularly in protracted cases. The former will be employed with most probability of success, when symptoms of a menstrual effort appear. They are, especially the hip-bath, fomentations to the hypogastrium, sitting over a vessel of hot water, so that the vapour may be applied to the pudenda; with antispasmodic medicines, as the compound galbanum pill, castor, &c. but especially opium. If the patient be plethoric, venesection should be premised. In cases of long standing, the object will be to bring about a determination of blood to the uterus. This may be accomplished by emmenagogues, of which savine and the lytta are most to be depended upon; though the latter would be improper, if hematuria had occurred. Certain cathartics are also very useful, particularly aloes, which appear to operate especially on the rectum, and thus sympathetically influence the uterus. Electric shocks passed through the hypogastric region, may likewise contribute to the cure.

In cases of scanty and painful menstruation, the means pointed out above as calculated to take off constriction of the uterine vessels, should be resorted to; especially the hip-bath, and the free use of opium.

AME'NTIA. (From α, priv. and *mens* the mind.) Imbecillity of intellect, by which the relations of things are either not perceived, or not recollected. A disease in the class *neuroses*, and order *vesaniæ* of Cullen. When it originates at birth, it is called *amentia congenita*, natural stupidity; when from the infirmities of age, *amentia senilis*, dotage or childishness; and when from some accidental cause, *amentia acquisita.*

American balsam. See *Myroxylon Peruiferum.*

AMERICA'NUM TUBERO'SUM. The potatoe. An American tuberose root. See *Solanum.*

AMETHY'STA PHA'RMACA. (From α, neg. and μεθυ, wine.) Medicines which were said either to prevent or remove the effects of wine. *Galen.*

AMETHY'STUS. (From α, neg. and μεθυσκω, to be inebriated.) The amethyst. A precious stone, so called, because in former times, according to Plutarch, it was thought to prevent drunkenness. *Ruland. in Lex. Chem.*

AMI'CULUM. A little short cloak. It is the same as the amnios, but antiently meant a covering for the pubes of boys, when they exercised in the gymnasium. *Rhodius.*

A'MIDUM. See *Amylum.*

AMINÆ'UM. A wine produced in Aminæa, formerly a province of Italy; called also Salernum. Also a strong wine vinegar. Galen mentions Aminæum Neapolitanum, and Aminæum Siculum.

A'MMI. (Αμμι: from αμμος, sand, from its likeness to little gravel-stones.) 1. The name of a genus of plants in the Linnæan system. 2. The pharmacopæial name of the herb bishop's weed, of which there are two sorts, the *ammi verum* and *vulgare.*

A'MMI MA'JUS. The systematic name for the *ammi vulgare* of the shops. The seeds of this plant, *Ammi majus*, of Linnæus; — *foliis inferioribus pinnatis, lanceolatis, serratis; superioribus, multifidis, linearibus*, are less powerful than those of the *Sison* *ammi*, but were exhibited with the same views.

A'MMI VE'RUM. See *Sison Ammi.*

A'MMI VULGA'RE. See *Ammi majus.*

A'MMION. *Ammium.* Cinnabar.

AMMOCHO'SIA. (From αμμος, sand, and χεω, to pour.) A remedy for drying the body by sprinkling it with hot sand. *Oribasius.*

AMMO'NIA ACETA'TA. See *Liquor acetatis ammoniæ.*

AMMO'NIA MURIA'TA. See *Sal ammoniac.*

AMMO'NIA PRÆPARA'TA. See *Subcarbonas ammoniæ.*

AMMO'NIA. Ammonia-gas. The substance so called, is an aëriform or gaseous body.

Pure ammonia appears to be a compound of hydrogen and nitrogen, rendered gaseous by caloric. If a portion of it well dried be subjected to repeated electrical explosions, its bulk becomes gradually almost doubled, being resolved into hydrogen and nitrogen gases, of which the latter constitutes only one-fourth by measure of the result; and therefore the proportions by weight are about:

18 hydrogen
82 nitrogen

100

If some liquid ammonia be subjected to the galvanic influence in contact with mercury, a substance resembling an amalgam is formed: but whether this be a compound of ammonia and mercury, or consist of the latter united to some element of ammonia, is uncertain. Berzelius who made the discovery, considers the volatile alkali to be a compound of oxygen, and a metallic substance, which he calls ammonium.

Ammonia-gas has a strong and very pungent odour. It extinguishes flame, yet it increases the magnitude of the flame of a taper before extinction, producing a pale yellow colour round its edge. Animals cannot breathe it without death ensuing. It is lighter than atmospheric air, in the proportion of three to five. It tinges yellow vegetable colours brown, and blue ones green. It is rapidly absorbed by cold water; by ardent spirit, essential oils, ether, charcoal, sponge, bits of linen cloth, and all porous bodies.

When a piece of ice is brought in contact with this gas, it melts and absorbs the gas, while at the same time its temperature is increased. It has no effect upon oxygen gas while cold; but when made to pass with it through an ignited tube, it denotates and becomes decomposed. The same is the case with common air. It is also decomposed by phosphorus at high temperatures.

It does not explode when mixed with hydrogen gas. Nitrogen gas has no effect upon it. Atmospheric air does not combine with it at common temperatures, but only mixes with and dilutes it. When made to pass through ignited charcoal, it forms with it a substance called prussic acid. If brought into contact with acid gases, both gases lose their gaseous form, and become concrete. It has no sensible action on earths, or on the *salino terrene* substances. It combines readily with acids, and unites to sulphur, when both are in a state of vapour. It reduces oxides of metals to their metallic state, and is decomposed by them. It is also decomposed by oxigenated muriatic acid gas, &c.—When liquid ammonia is exposed to the temperature of 46 degrees below 0, it crystallizes, and when suddenly cooled down to 68 degrees below 0, it assumes a gelatinous appearance, and has scarcely any odour.

Methods of obtaining Ammonia.—1. Mix together equal quantities of muriate of ammonia and quick-lime, separately powdered; introduce them into a gas-bottle or retort, apply the heat of a lamp, and receive the gas over mercury.

Explanation.—Muriate of ammonia consists of muriatic acid and ammonia; on adding lime to it, a decomposition takes place, the muriatic acid quits the ammonia and unites to the lime, forming muriate of lime, which remains in the retort, and the ammonia flies off in the state of gas.

Remark.—In order to obtain the gas in a state of purity, it is essentially necessary that a considerable quantity of the gas first disengaged, be suffered to escape, on account of the common air contained in the distilling vessel, and in the interstices of the ingredients.

2. Ammonia may likewise be obtained by heating the liquid ammonia of the shops (liquor ammoniæ, *Pharm. Lond.*) in a retort placed in communication with the mercurial pneumatic trough.

In this process the ammonia contained in this liquid combines with caloric, assumes the form of ammonia-gas, and parts with the water to which it was united.

Remark.—The temperature of the fluid must not be carried so high as to cause the water to be converted into vapour, or, if this cannot well be avoided, a small vessel should be interposed between the retort and the receiver, which, when kept cool, may serve to condense the aqueous vapour which is formed, and cause the ammonia-gas to pass in a very pure and dry state.

Ammonia is likewise produced during the spontaneous decomposition of animal and vegetable substances; in these cases it did not pre-exist in them ready formed, but is generated by the union of the hydrogen and nitrogen contained in them.

In combination with water, this alkali forms a solution of, or liquid ammonia, which is called, in the London pharmacopœia, LIQUOR AMMONIÆ.

Take of muriate of ammonia, eight ounces.
Lime newly prepared, six ounces.
Water, four pints.

Pour on the lime a pint of the water; then cover the vessel, and set them by for an hour; then add the muriate of ammonia, and the remaining water previously made boiling hot, and cover the vessel again; strain the liquor when it has cooled; then distil from it twelve fluid ounces of the solution of ammonia. The specific gravity of this solution should be to that of distilled water, as 96 to 100.

Lime is capable of decomposing muriate of ammonia at a temperature much below that of boiling water; so that when the materials are mixed, a solution of ammonia and of muriate of lime is obtained. This being submitted to distillation, the ammonia passes over with a certain portion of the water, leaving behind the muriate of lime dissolved in the rest. The proportion of water directed seems, however, unnecessarily great, which obliges the operator to employlarger vessels than would otherwise suffice. But the process now directed is certainly much easier, more economical, and more uniform in its results, than that of the Pharmacopœia of 1809.

This preparation is colourless and transparent with a strong peculiar smell; it parts with the ammonia in the form of gas, if heated to 130 degrees, and requires to be kept, with a cautious exclusion of atmospherical air, with the carbonic acid of which it readily unites: on this latter account, the propriety of keeping it in small bottles instead of a large one, has been suggested.

This is the *aqua ammoniæ puræ* of the shops, and the *alkali volatile causticum*.

Water of ammonia is very rarely given internally, although it may be used in doses of ten or twenty drops, largely diluted, as a powerful stimulant in asphyxia and similar diseases. Externally, it is applied to the skin as a rubefacient, and in the form of gas to the nostrils, and to the eyes as a stimulant: in cases of torpor, paralysis, rheumatism, syncope, hysteria, and chronic ophthalmia.

The other preparations of ammonia in use are,

1. The sub-carbonate of ammonia. See *Ammoniæ subcarbonas*, and *ammoniæ subcarbonatis liquor*.
2. The acetate of ammonia. See *ammoniæ acetatis liquor*.
3. The muriate of ammonia. See *Sal-ammoniac*.
4. Ferrum ammoniatum.
5. Several tinctures and spirits, holding ammonia in solution.

AMMONI'ACUM. (Αμμονιακον: so called from *Ammonia*, whence it was brought.) *Gum-ammoniac.* A concrete gummy resinous juice, composed of little lumps, or tears, of a strong and somewhat ungrateful smell, and nauseous taste, followed by a bitterness. There has, hitherto, been no information had concerning the plant which affords this drug: but Wildenow considers it to be the *Heracleum gummiferum*, having raised that plant from the seeds, which are sometimes found in the drug. It is imported here from Turkey, and from the East-Indies. Gum-ammoniacum is principally employed as an expectorant, and is frequently prescribed in asthma and chronic catarrh. Its dose is from 10 to 30 grains. It is given in the form of pill or diffused in water, and is frequently combined with squill, or tartarised antimony. In large doses, it proves purgative. Externally, it is applied as a discutient, under the form of plaster, to white swellings of the knee, and to indolent tumours. The officinal preparations are Ammoniacum purificatum: Emplastrum ammoniaci: Empl. ammoniaci cum hydragyro; Mistura ammoniaci.

AMMONI'Æ ACETATIS LIQUOR. Solution of acetate of ammonia; formerly called *Aqua ammoniæ acetæ*. "Take of sub-carbonate of ammonia, two ounces; acetic acid, four pints. Add the acid to the salt, until bubbles of gas shall no longer arise, and mix." The effervescence is occasioned by the escape of carbonic acid gas, which the acetic acid expels, and neutralises the ammonia.

If the acid rather predominate, the solution is more grateful to the taste; and provided that acid be correctly prepared, the proportions here given will be found sufficient; where the acid cannot be depended on, it will be right to be regulated rather by the cessation of effervescence than by quantity.

This preparation was formerly known in the shops under the name of spirit of Mindererus. When assisted by a warm regimen, it proves an excellent and powerful sudorific; and, as it operates without quickening the circulation, or increasing the heat of the body, it is admissible in febrile and inflammatory diseases, in which the use of stimulating sudorifics are attended with danger. Its action may likewise be determined to the kidneys, by walking about in the cool air. The common dose is half an ounce, either by itself, or along with other medicines, adapted to the same intention.

Ammóniæ carbónas. See *Ammoniæ subcarbonas.*

Ammóniæ Liquor. See *Ammonia.*

Ammóniæ múrias. See *Sal-ammoniac.*

AMMO'NIÆ SUBCARBO'NAS. *Ammoniæ carbonas.* Subcarbonate of ammonia. This preparation was formerly called *ammonia præparata*, and *sal volatilis salis ammoniaci*, and *sal volatilis*. It is made thus:—take of muriate of ammonia, a pound; of prepared chalk, dried, a pound and a half. Reduce them separately to powder; then mix them together, and sublime in a heat gradually raised, till the retort becomes red. In this preparation a double decomposition takes place, the carbonic acid of the chalk uniting with the ammonia, and forming subcarbonate of ammonia, which is volatilised, while muriate of lime remains in the vessel.

This salt possesses nervine and stimulating powers, and is highly beneficial in the dose of from two to eight grains, in nervous affections, debilities, flatulency, and acidity from dyspepsia.

Ammo'niæ subcarbona'tis liquor. *Liquor ammoniæ carbonatis.* Solution of subcarbonate of ammonia. The *aqua ammoniæ* of the Pharm. Lond. 1787. "Take of subcarbonate of ammonia, four ounces; distilled water, a pint. Dissolve the subcarbonate of ammonia in the water, and filter the solution through paper." This preparation possesses the properties of ammonia in its action on the human body. See *Ammoniæ subcarbonas.*

Ammo'nion. (From *αμμος*, sand.) Aëtius uses this term to denote a collyrium of great virtue in many diseases of the eye, which was said to remove sand or gravel from the eyes.

AMMO'NIUM. Berzelius has given this name to a supposed metal which with oxygen he conceives to form the alkali called ammonia. See *Ammonia.*

Amne'sia. (From *α*, priv. and *μνησις*, memory.) *Amnestia.* Forgetfulness; mostly a symptomatic affection.

Amne'stia. See *Amnesia.*

A'MNIOS. *Amnion.* (From *αμνος*, a lamb, or lamb's skin.) The soft internal membrane which surrounds the fœtus. It is very thin and pellucid in the early stage of pregnancy, but acquires considerable thickness and strength in the latter months. The amnios contains a thin watery fluid, in which the fœtus is suspended. In the abortion of the early months, we find the quantity of this fluid very great, in proportion to the whole ovum, and the amnios forms a delicate and almost gelatinous substance, and is a provision for the regular presentation of the head of the child; for now, the fœtus being suspended in the fluid, and hanging by the umbilicus, and the head and upper part of the body greatly preponderating, it takes that position with the head presenting to the orifice of the womb, which is necessary to natural and safe labour, the fœtus being prevented from shifting, in the latter months by the closer embracing of the child with the uterus.

AMNIO'TIC A'CID. Vauquelin and Buniva have discovered a peculiar acid in the liquor of the amnios of the cow, to which they have given the name of amniotic acid.

It exists in the form of a white pulverulent powder. It is slightly acid to the taste, but sensibly reddens vegetable blues. It is difficulty soluble in cold, but readily soluble in boiling water, and in alcohol. When exposed to a strong heat, it exhales an odour of ammonia and of prussic acid. Assisted by heat, it decomposes carbonate of potash, soda, and ammonia. It produces no change in the solutions of silver, lead, or mercury, in nitric acid.

Amniotic acid may be obtained by evaporating the liquor of the amnios of the cow to a fourth part, and suffering it to cool; crystals of amniotic acid will be obtained in considerable quantity.

Whether this acid exists in the liquor of the amnios of other animals, is not yet known.

AMO'MUM. (From an Arabian word, signifying a pigeon, whose foot it was thought to resemble.) The name of a genus of plants in the Linnæan system. Class, *Monandria.* Order, *Monogynia.*

Amo'mum verum. True stone parsley. The fruit is about the size of a grape, of a strong and grateful aromatic taste, and penetrating smell. The seeds have been given as a carminative.

Amo'mum cardamo'mum. The former systematic name for the *cardamomum minus.* See *Elettaria cardamomum.*

Amo'mum gra'num paradisi. The systematic name of the plant which affords the grains of paradise. *Cardamomum majus. Meleguetta maniguetta. Cardamomum piperatium.* They are angular reddish brown seeds, smaller than pepper, and resembling very much the seeds of the cardamomum minus. They are extremely hot, and similar in virtue to pepper.

Amo'mum zingiber. The former systematic name of the plant which affords ginger. See *Zingiber Officinale.*

Amo'rge. See *Amurca.*

Ampelosa'gria. From *αμπελος*, a vine, and *αγριος*, wild.) See *Bryonia.*

Amphemeri'nos. (From *αμφι*, about, and *ημερα*, a day.) *Amphemerina.* A quotidian fever. A species of ague.

AMPHIARTHRO'SIS. (*Αμφιαρθρωσις*: from *αμφι*, both, and *αρθρωσις*, an articulation; so called from its partaking both of diarthrosis and synarthrosis.) A mixed species of connexion of bones, which admits of an obscure motion, as is observed in the metacarpal and metatarsal bones, and the vertebræ.

Amphibious. (From *αμφι*, *ambo*, and *βιος*, *vita.*) Animals are thus called, that live both on land and in the water. The *amphibious* animals, according to Linnæus, are a class whose heart is furnished with one ventricle and one auricle, in which respiration is in a considerable degree voluntary.

Amphiblestroi'des. (From *αμφιβληστρον*, a net, and *ειδος*, a resemblance.) The retina, or net-like coat of the eye.

Amphibra'nchia. (From *αμφι*, about, and *βραγχια*, the jaws.) The fauces or parts about the tonsils, according to Hippocrates and Foësius.

Amphicau'stis. (From αμφι, about, and καυςις, ripe corn, *pudendum muliebre.*) A sort of wild barley. Eustachius says it was also to express the private parts of a woman.

Amphideon. (From αμφι, on both sides, and δαιω to divide.) *Amphidæum. Amphidium.* The os tincæ, or mouth of the womb, which opens both ways, was so called by the antients.

Amphidiarthro'sis. The same as amphiarthrosis.

Amphimeri'na. (From αμφι, about, and ημερα a day.) An intermitting fever of the quotidian kind.

Amphime'trion. (From αμφι, about, and μητρα, the womb.) *Amphimetrium.* The parts about the womb. *Hippocrates.*

A'mphiplex. (From αμφν, about, and ϖλεκτω, to connect.) According to Rufus Ephesius, the part situated between the scrotum and anus, and which is connected with the thighs.

Amphipneu'ma. (From αμφι, about, and ϖνευμα, breath.) A difficulty of breathing. Dyspnœa. *Hippocrates.*

Amphi'polos. (From αμφι, about, and ϖολεω, to attend.) *Amphipolus.* One who attends the bed of a sick person, and administers to him. *Hippocrates.*

Amphismi'la. (From αμφι, on both sides, and σμιλη, an incision-knife.) A dissecting knife, with an edge on both sides. *Galen.*

AMPU'LLA. (αμβολλα, from αναβαλλω, to swell out.) A bottle.

1. All bellied vessels are so called in chemistry, as bolt-heads, receivers, cucurbits, &c.

2. In anatomy this term is applied by Scarpa to the dilated portions of the membranaceous semicircular canals, just within the vestibulum of the ear.

Ampulle'scens. (From *ampulla*, a bottle.) The most tumid part of Pecquet's duct is called alveus ampullescens.

Amputa'tio. (From *amputo*, to cut off.) *Ectome.* A surgical operation, which consists in the removal of a limb or viscus; thus we say a leg, a finger, the penis, &c. when cut off, are amputated; but when speaking of a tumour, or excrescence, it is said to be dissected out or removed.

Amule'tum. (From αμμα, a bond; because it was tied round the person's neck; or rather from αμυνω, to defend.) An amulet, or charm; by wearing which the person was supposed to be defended from the admission of all evil; in particular, an antidote against the plague.

Amu'rca. (From αμεργω, to press out.) *Amorge.* A small herb, whose expressed juice is used in dying. Also the sediment of the olive, after the oil has been pressed from it; recommended by Hippocrates and Galen as an application to ulcers.

Amu'tica. (From αμυττω, to scratch.) Medicines that, by vellicating or scratching, as it were, the bronchia, stimulate it to the discharge of whatever is to be thrown off the lungs.

A'myche. (From αμυσσω, to scratch.) A superficial laceration or exulceration of the skin: a slight wound. *Hippocrates.*—Scarification. *Galen.*

Amy'ctica. (From αμυσσω, to vellicate.) Medicines which stimulate and vellicate the skin, according to Cælius Aurelianus.

AMY'GDALA. (Αμυγδαλη, from αμυσσω, to lancinate; so called, because after the green husk is removed from the fruit, there appear upon the shell certain fissures, as it were lacerations.) The almond. See *Amygdalus.*

Amy'gdala dulcis. See *Amygdalus.*

Amy'gdala ama'ra. See *Amygdalus.*

Amy'gdalæ. The tonsils, so called from a supposed resemblance to almonds.

AMY'GDALUS. The name of a genus of plants in the Linnæan system. Class, *Icosandria.* Order, *Monogynia.* The almond-tree.

Amy'gdalus commu'nis. The pharmacopœial name of the common almond. *Amygdalus communis* of Linnæus:—*foliis serratis infimis glandulosis, floribus sessilibus geminis.*

The almond is a native of Barbary. The same tree produces either bitter or sweet. Sweet almonds are more in use as food than medicine; but they are said to be difficult of digestion, unless extremely well comminuted. Their medicinal qualities depend upon the oil which they contain in the farinaceous matter, and which they afford on expression, nearly in the proportion of half their weight. It is very similar to olive oil; perhaps rather purer, and is used for the same purposes. The oil thus obtained is more agreeable to the palate than most of the other expressed oils, and is therefore preferred for internal use, being generally employed with a view to obtund acrid juices, and to soften and relax the solids, in tickling coughs, hoarseness, costiveness, nephritic pains, &c. externally it is applied against tension and rigidity of particular parts. The milky solutions of almonds in watery liquors, usually called emulsions, possess, in a certain degree, the emollient qualities of the oil, and have this advantage over pure oil, that they may be given in acute or inflammatory disorders, without danger of the ill effects which the oil might sometimes produce by turning rancid. The officinal preparations of almonds, are the expressed oil, the confection, and the emulsion; to the latter, the addition of gum-arabic is sometimes directed, which renders it a still more useful demulcent in catarrhal affections, stranguries, &c.

Bitter almonds yield a large quantity of oil, perfectly similar to that obtained from sweet almonds, but the matter remaining after the expression of the oil, is more powerfully bitter than the almond in its entire state. Great part of the bitter matter dissolves by the assistance of heat, both in water and rectified spirit; and a part arises also with both menstrua in distillation. Bitter almonds have been long known to be poisonous to various brute animals; and some authors have alleged that they are also deleterious to the human species; but the facts recorded upon this point appear to want further proof. However, as the noxious quality seems to reside in that matter which gives it the bitterness and flavour, it is very probable, that when this is separated by distillation, and taken in a sufficiently concentrated state, it may prove a poison to man, as is the case with the common laurel, to which it appears extremely analogous. Bergius tells us, that bitter almonds, in the form of emulsion, cured obstinate intermittents, after the bark had failed. A simple water is distilled from bitter almonds, after the oil is pressed out, which possesses the same qualities, and in the same degree, as that drawn from cherry-stones. These afforded, formerly, the now exploded aqua cerasorum nigrorum, or black-cherry-water.

Amy'gdalus pe'rsica. The systematic name of the common peach-tree. The fruit is known to be grateful and wholesome, seldom disagreeing with the stomach, unless this organ is not in a healthy state, or the fruit has been eaten to excess, when effects similar to those of the other dulco-acid summer fruits may be produced. The flowers, including the calyx, as well as the corolla, are the parts of the persica used for medicinal purposes. These have an agreeable but weak smell, and a bitterish taste. Boulduc observes, "that when distilled, without addition, by the heat of a water bath, they yield one sixth their weight, or more, of a whitish liquid, which communicates to a considerable quantity of other liquids a flavour like that of the kernels of fruits. These flowers have a cathartic effect, and, especially to children, have been successfully given in the character of a vermifuge; for this purpose, an infusion of a dram of the flowers dried, or half an ounce in their recent state, is the requisite dose. The leaves of the persica are also found to possess an anthelmintic power, and from a great number of experiments appear to have been given with invariable success both to children and adults. However, as the leaves and flowers of the persica manifest, in some degree, the quality of those of the laurocerasus, they ought to be used with caution.

A'myla. (From *amylum*, starch.) Any sort of chemical fæcula, or highly pulverized residuum.

Amy'leon. *Amylion.* Starch.

A'MYLUM. (Αμυλον: from α, priv. and μυλη, a mill; because it was formerly made from wheat, without the assistance of a mill.) Starch. The fæcula of wheat, or starch of wheat. The white substance which subsides from the water that is mixed with wheaten flour. The starch-makers suffer it to remain in the water for a time after it has become acid, which makes it very white and soft to the touch, and scarcely sensible to the taste. As starch forms the greatest part of flour, it cannot be doubted but that it is the principal alimentary substance contained in our bread. In a medical point of view, it is to be considered as a demulcent; and, accordingly, it forms the principal ingredient of an officinal lozenge in catarrhs, and a mucilage prepared from it, often produces excellent effects, both taken by the mouth and in the form of clyster, in dysenteries and diarrhœa, from irritation of the intestines. Milk and starch, with the addition of suet finely shred, and incorporated by boiling, was the soup employed by Sir John Pringle, in dysenteries, where the mucous membrane of the intestines had been abraded. Externally, surgeons apply it as an absorbent in erysipelas.

AMY'RIS. (From α, intensive, and μυρον, ointment, or balm; so called from its use, or smell.) The name of a genus of plants in the Linnæan system, of which two species are used in medicine.

Amy'ris Elemifera. The systematic name of the plant from which it is supposed we obtain the resin called *gum-elemi.* The plant is described as *Amyris elemifera* of Linnæus: *foliis ternis quinato-pinnatisque subtus tomentosis.* Elemi is brought here from the Spanish West Indies: it is most esteemed when softish, somewhat transparent, of a pale whitish colour, inclining a little to green, and of a strong, though not unpleasant smell. It is only used in ointments and plasters, and is a powerful digestive.

Amy'ris opoba'lsamum. The systematic name of the plant from which the balsam of Mecca is obtained. *Balsamum genuinum antiquorum. Balsamelæon. Ægyptiacum balsamum. Balsamum Asiaticum. Balsamum Judaicum. Balsamum Syriacum. Balsamum e Meccâ. Balsamum Alpini. Oleum balsami. Opobalsamum. Xylobalsamum.* Balsam, or balm of Gilead. A resinous juice, obtained by making incisions into the bark of the *Amyris Gileadensis* of Linnæus—*foliis ternatis integerrimis, pedunculis unifloris lateralibus.* Class, *Octandria.* Order, *Monogynia.* The tree grows spontaneously, particularly near to Mecca, on the Asiatic side of the Red Sea. The juice of the fruit is termed *carpobalsamum* in the pharmacopœias, and that of the wood and branches *xylobalsamum.* The best sort is a spontaneous exudation from the tree, and is held in so high estimation by the Turks, that it is rarely, if ever, to be met with genuine among us. The medicinal virtues of the genuine balsam of Gilead, have been highly rated, undoubtedly with much exaggeration. The common balsam of Mecca is scarcely used; but its qualities seem to be very similar to those of the balsam of Tolu, with perhaps more acrimony. The dose is from 15 to 50 drops.

A'myum. (From α, priv. and μυς, muscle.) A limb so emaciated that the muscles scarcely appear.

ANA. ā, or āā. In medical prescriptions it means "of each." See *A.*

Ana'basis. (From αναβαινω, to ascend.) An ascension, augmentation, or increase of a disease, or paroxysm. It is usually meant of fevers. *Galen.* It also signifies equisetum.

Anaba'tica. (From αναβαινω, to ascend.) An epithet formerly applied to the synochus, or continual fever, when it increases in malignity.

Anabe'xis. (From αναβηττω, to cough up.) An expectoration of matter by coughing.

Anable'psis. (From ανα and βλεπω, to see again.) The recovery of sight after it has been lost.

Anablysis. (From ανα and βλυζω, to gush out again.) Ebullition or effervescence.

Ana'bole. (From αναβαλλω, to cast up.) The discharge of any thing by vomit; also dilatation, or extension. *Galen.*

Anabroche'sis. (From ανα and βροχεω, to resorb.) The reabsorption of matter.

Anabrochi'smos. (From αναβροχεω, to reabsorb.) *Anabrochismus.* The taking up and removing the hair on the eyelids, when they become troublesome. *Galen, Ægineta,* and others.

Anabro'sis. (From αναβροσκω, to devour.) A corrosion of the solid parts, by sharp and biting humours. *Galen.*

Anaca'rdium occidenta'le. (From ανα, without, and καρδια, a heart; without heart; because the pulp of the fruit, instead of having the seed inclosed, as is usually the case, has the nut growing out of the end of it.) The cashew-nut. The oil of this nut is an active caustic, and employed as such in its native country; but neither it, nor any part of the fruit, is used medicinally in this country.

Anaca'rdium orienta'le, Anacardium or Malacca bean. *See Avicennia.*

Anacatha'rsis. (From ανα, and καθαιρομαι, to purge up.) An expectoration of pus. It properly denotes a purgation by spitting, in which sense it stands contradistinguished from catharsis, or evacuation downwards. In this sense the word is used by Hippocrates and Galen. Blanchard denotes, by this word, medicines which operate upwards, as vomiting, &c.

Anacatha'rtica. (From ανακαθαιρομαι, to purge upwards. *Thoracia.* Medicines which promote expectoration, or vomits which act upwards.

Ana'chron. Mineral alkali.

Ana'clasis. (From ανακλαω, to bend back.) A reflection or recurvature of any of the members, according to Hippocrates.

Ana'clisis. (From ανακλενω, to recline.) A couch, or sick-bed. *Hippocrates.*

Anacœlia'smus. (From ανα, and κοιλια, the bowels.) A gentle purge, which was sometimes used to relieve the lungs.

Anaco'che. (From ανακωχεω, to retard.) Delay in the administration of medicines; also slowness in the progress of a disease. *Hippocrates.*

Anacolle'ma. (From ανα, and κολλαω, to glue together.) A collyrium made of agglutinant substances, and stuck on the forehead. *Galen.*

Anaconcholi'smos. (From ανακογχυλιζω, to sound as a shell.) A gargarism so called, because the noise made in the throat is like the sound of a shell. *Galen.*

Anacte'sis. (From ανακταομαι to recover.) Restoration of strength; recovery from sickness. *Hippocrates.*

Anacuphi'sma. (From ανακουφιζω, to lift up.) A kind of exercise mentioned by Hippocrates, which consists in lifting the body up and down, like our weigh jolt.

Anacyce'sis. (From ανακυκαω, to mix.) The commixture of substances, or medicines, by pouring one upon another.

Anacy'cleon. (From ανακυκλοω, to wander about.) *Anacycleus.* A mountebank, or wandering quack.

Anacyri'osis, (From ανα, and κυρος, authority.) By this word, Hippocrates means that gravity and authority which physicians should preserve among sick people and their attendants.

Anadiplo'sis. (From αναδιπλοω, to reduplicate.) A reduplication or frequent return of a paroxysm, or disease. *Galen.*

Ana'dosis. (From ανω, upwards, and διδωμι; to give.) A vomit, or the distribution of aliment all over the body; or digestion.

Ana'drome. (From ανω, upwards, and δρεμω, to run.) A pain which runs from the lower extremities to the upper parts of the body. *Hippocrates.*

Anæ'des. (From α, priv. and αιδως, shame.) Shameless. Hippocrates uses this word metaphorically for without restraint, copious; and applies it to water rushing into the aspera arteria.

ANÆSTHE'SIA. (Αναισθησια: from α, priv. and αισθανομαι, to feel.) Loss of the sense of touch. A genius of disease in the class *locales,* and order *dysæsthesiæ* of Cullen.

ANAGA'LLIS. (From αναγελαω, to laugh; because, by curing the spleen, it disposes persons to be cheerful.) 1. The name of a genus of plants in the Linnæan system one species of which was formerly supposed to possess medicinal properties.

2. The pharmacopœial name of the

Anagallis arvensis; foliis indivisis, caule procumbente, of Linnæus, a small and delicately formed plant, which does not appear to possess any particular properties.

Anaga′llis arve′nsis. The systematic name for the *anagallis* of the shops. See *Anagallis.*

Anagargali′ctum. (From ανα, and γαργαρεων, the throat.) A gargarism, or wash for the throat.

Anagargari′stum. The same.

Anagly′phe. (From αναγλυφω, to engrave.) A part of the fourth ventricle of the brain was formerly thus called, from its resemblance to a pen, or style.

Anagno′sis. (From αναγινωσκω, to know.) The persuasion, or certainty, by which medical men judge of a disease from its symptoms. *Hippocrates.*

Ana′graphe. (From αναγραφω, to write.) A prescription or receipt.

Anale′psia. (From ανα, and λαμβανω, to take again.) A species of epilepsy, which proceeds from a disorder of the stomach, and with which the patient is apt to be seized very often and suddenly.

Anale′ntia. A fictitious term used by Paracelsus for epilepsy.

Anale′psis. (From αναλαμβανω, to restore.) A recovery of strength after sickness. *Galen.*

ANALE′PTICA. (From αναλαμβανω, to recruit or recover.) *Analeptics.* Restorative medicines; medicines, or food, which recover the strength which has been lost by sickness.

Analo′sis. (From αναλισκω, to consume.) A consumption, or wasting.

ANA′LYSIS. (Αναλυσις: from αναλυω, to resolve.) The resolution by chemistry, of any matter into its primary and constituent parts. The processes and experiments which chemists have recourse to, are extremely numerous and diversified, yet they may be reduced to two species, which comprehend the whole art of chemistry. The first is, *analysis,* or decomposition; the second, *synthesis,* or composition. In *analysis,* the parts of which bodies are composed, are separated from each other: thus, if we reduce cinnabar, which is composed of sulphur and mercury, and exhibit these two bodies in a separate state, we say we have decomposed, or analysed cinnabar. But if, on the contrary, several bodies be mixed together, and a new substance be produced, the process is then termed chemical composition, or *synthesis:* thus, if by fusion and sublimation, we combine mercury with sulphur, and produce cinnabar, the operation is termed chemical composition, or composition by synthesis.

Anamne′sis. (From αναμιμνησκω, to remember.) Remembrance, or recollection of what has been done. *Galen.*

Anamne′stica. (From the same.) Remedies for bad memory.

ANA′NAS. Called by the Brazilians yayama. The egg-shaped pine-apple. See *Bromelia Ananas.*

Ana′nce. (From αναγκαζω, to compel.) Necessity. It is applied to any desperate operation. *Hippocrates.*

Anaphalanti′asis. (From αναφαλαντος, bald.) A thinness of hair upon the eyebrows. *Gorræus.*

Ana′phora. (From αναφερω, to bring up.) It is applied to a person who spits blood. *Gorræus.*

Anaphory′xis. (From αναφορυσσω, to grind down.) The reducing of any thing to dust, or a very fine powder.

ANAPHRODI′SIA. (From α, priv. and Αφροδισια, the feast of Venus.) Impotence. A genus of disease in the class *locales,* and order *dysorexiæ* of Cullen. It either arises from paralysis, *anaphrodisia paralytica;* or from gonorrhœa, *anaphrodisia gonorrhoica.*

Anaphro′meli. (From α, neg. αφρος, froth, and μελι, honey.) Clarified honey.

Anapla′sis. (From αναπλασσω, to restore again.) A restoration of flesh where it has been lost; also the reuniting a fractured bone. *Hippocrates.*

Anaplero′sis. (From αναπληροω, to fill again.) The restitution, or filling up of wasted parts. *Galen.*

Anaplero′tica. (From the same.) Medicines renewing flesh: incarnatives, or such medicines as fill up a wound so as to restore it to its original shape. *Galen.*

Anapleu′sis. (From αναπλευω, to float upon.) The rotting of a bone, so that it drops off, and lies upon the flesh; exfoliation, or separation of a bone. *Hippocrates, Ægineta,* &c.

Anapneu′sis. (From αναπνεω, to respire.) Respiration.

Ana′pnoe. The same.

Anapto′sis. (From ανάπιπτω, to fall back.) A relapse.

Ana′ptysis. The same as *Anacatharsis.*

Anarrhegni′mia. (From ανα, and ῥηγνυμι, to break again.) *Anarrhexis.* A fracture; the fresh opening of a wound.

Anarrhœ′a. (From ανα, upwards, and ῥεω, to flow.) A flux of humours from below upwards. *Schneider de Catarrho.*

Anarrho′pia. (From ανα, upwards, and ῥεπω, to creep.) The same. *Hippocrates.*

A′NAS DOME′STICA. (From νεω, to swim.) The tame duck. The flesh of this bird is difficult of digestion, and requires that warm and stimulating condiments be taken with it to enable the stomach to digest it.

ANASA′RCA. (From ανα, through, and σαρξ, flesh.) A species of dropsy from a serous humour, spread between the skin and flesh, or rather a general accumulation of lymph in the cellular system. Dr. Cullen ranks this genus of disease in the class *Cachexiæ,* and the order *Intumescentiæ.* He enumerates the following species, viz. 1. *Anasarca serosa*, as when the due discharge of serum is suppressed, &c. 2. *Anasarca oppilata*, as when the blood-vessels are considerably pressed, which happens to many pregnant women, &c. 3. *Anasarca exanthematica*, this happens after ulcers, various eruptive disorders, and particularly after the *erysipelas*. 4. *Anasarca anæmia*, happens when the blood is rendered extremely poor from considerable losses of it. 5. *Anasarca debilium*, as when feebleness is induced by long illness, &c.

This species of dropsy shews itself at first with a swelling of the feet and ankles towards the evening, which, for a time, disappears again in the morning. The tumefaction is soft and inelastic, and, when pressed upon by the finger, retains its mark for some time, the skin becoming much paler than usual. By degrees the swelling ascends upwards, and occupies the trunk of the body; and at last, even the face and eyelids appear full and bloated: the breathing then becomes difficult, the urine is small in quantity, high coloured, and deposits a reddish sediment; the belly is costive, the perspiration much obstructed, the countenance yellow, and a considerable degree of thirst, with emaciation of the whole body, prevails. To these symptoms succeed torpor, heaviness, a troublesome cough, and a slow fever. In some cases, the water oozes out, through the pores of the cuticle; in others, being too gross to pass by these, it raises the cuticle in small blisters; and sometimes the skin, not allowing the water to escape through it, is compressed and hardened, and is at the same time, so much distended as to give the tumour a considerable degree of firmness. For the causes of this disease, see *Hydrops*.

In those who have died of Anasarca, the whole of the cellular membrane has been distended with a fluid, mostly of a serous character. Various organic diseases have occurred; and the blood is said to be altered in consistence, according to the degree of the disease. In general a cure can be more readily effected when it arises from topical or general debility, than when occasioned by visceral obstruction; and in recent cases, than in those of long continuance. The skin becoming somewhat moist, with a diminution of thirst, and increased flow of urine, are very favourable. In some few cases the disease goes off by a spontaneous crisis by vomiting, purging, &c. The indications of treatment in anasarca are, 1. To evacuate the fluid already collected. 2. To prevent its returning again. The first object may be attained mechanically by an operation; or by the use of those means, which increase the action of the absorbents: the second by removing any exciting causes, which may still continue to operate; and at the same time endeavouring to invigorate the system. Where the quantity of fluid collected is such, as to disturb the more important functions, the best mode of relieving the patient is to make a few small incisions with a lancet, not too near each other, through the integuments on the fore and upper part of each thigh; the discharge may be assisted by pressure, and when a sufficient quantity has been evacuated, it is better to heal them by the first intention. In the use of issues or blisters, there is some risk of inducing gangrene, especially if applied to the legs: and the same has happened from scarifications with the cupping instrument. Absorption may be promoted by friction, and bandaging the parts, which will at the same time obviate farther effusion; but most powerfully by the use of different evacuating remedies, especially those which occasion a sudden considerable discharge of fluids. Emetics have been often employed with advantage; but it is necessary to guard against weakening the stomach by the frequent repetition of those which produce much nausea; and perhaps the benefit results not so much from the evacuation produced by the mouth, as from their promoting other excretions; antimonials in particular inducing perspiration, and squill increasing the flow of urine, &c.; for which purpose they may be more safely given in smaller doses: in very torpid habits mustard may claim the preference. Cathartics are of much greater and more general utility: where the bowels are not particularly irritable, the more drastic purgatives should be employed, and repeated as often as the strength will allow; giving for example, every second or third morning jalap, scammony, colocynth or gamboge, joined with calomel or the supertartrate of potash, and some aromatic, to obviate their griping. Elaterium is perhaps the most powerful, generally vomiting as well as purging the patient, but precarious in its strength, and therefore better given in divided doses, till a sufficient effect is produced. Diuretics are universally proper, and may be given in the intervals, where purgatives can be borne, otherwise constantly persevered in; but unfortunately the effects of most of them are uncertain. Saline substances in general appear to stimulate the kidneys, whether acid, alkaline, or neutral; but the acetate, and supertartrate of potash, are chiefly resorted to in dropsy. Dr. Ferriar, of Manchester, has made an important remark of the latter salt, that its diuretic power is much promoted by a previous operation on the bowels, which encourages the more liberal use of it; indeed, if much relied upon, a drachm or two should be given three times or oftener in the day. It is obviously, therefore, best adapted to those cases, in which the strength is not greatly impaired; and the same holds with the nauseating diuretics, squill colchicum and tobacco. The latter has been strongly recommended by Dr. Fowler of York, in the form of tincture; the colchicum as an oxymel by some German physicians; but the squill is most in use, though certainly very precarious if given alone. In languid and debilitated habits, we prefer the more stimulant diuretics, as juniper, horseradish, mustard, garlic, the spiritus ætheris nitrici, &c.; even the oil of turpentine, or the tinctura lyttæ, may be proper, where milder means have failed. Digitalis is often a very powerful remedy, from the utility of which in inflammatory diseases we might expect it to answer best in persons of great natural strength, and not much exhausted by the disorder; but Dr. Withering expressly states that its diuretic effects appear most certainly and beneficially, where the pulse is feeble or intermitting, the countenance pale, the skin cold, and the tumours readily pitting on pressure; which has been since confirmed by other practitioners: it should be begun with in small doses two or three times a day, and progressively increased till the desired operation on the kidneys ensues, unless alarming symptoms appear in the meantime. Opium and some other narcotics have been occasionally useful as diuretics in dropsy, but should be only regarded as adjuvants, from their uncertain effects. In the use of diuretics, a very important rule is, not to restrict the patient from drinking freely. This was formerly thought necessary on theoretical grounds; whereby the thirst was aggravated to a distressing degree, and the operation of remedies often prevented, especially on the kidneys. Sir Francis Milman first taught the impropriety of this practice, which is now generally abandoned: at least so long as the flow of urine is increased in proportion to the drink taken, it is considered proper to indulge the patient with it. Another evacuation, which it is very desirable to promote in anasarca, is that by the skin, but this is with difficulty accomplished: nauseating emetics are the most powerful means, but transient in their effect, and their frequent use cannot be borne. If a gentle diaphoresis can be excited, it is as much as we should expect; and perhaps on the whole most beneficial to the patient. For this purpose the compound powder of ipecacuanha, saline substances, and antimonials in small doses, assisted by tepid drink, and warmth applied to the surface, may be had recourse to. Sometimes much relief is obtained by promoting perspiration locally by means of the vapour bath. Mercury has been much employed in dropsy, and certainly appears often materially to promote the operation of other evacuants, particularly squill and digitalis; but its chief utility is where there are obstructions of the viscera, especially the liver, of which, however, ascites is usually the first result: its power of increasing absorption hardly appears, unless it is carried so far as to affect the mouth, when it is apt to weaken the system so much, as greatly to limit its use. The other indication of invigorating the constitution, and particularly the exhalant arteries, may be accomplished by tonic medicines, as the several vegetable bitters, chalybeates in those who are remarkably pale, and, if there be a languid circulation, stimulants may be joined with them: a similar modification will be proper in the diet, which should be always as nutritious as the patient can well digest; directing also in torpid habits pungent articles, as garlic, onions, mustard, horseradish, &c. to be freely taken, which will be farther useful by promoting the urine. Rhenish wine, or punch made with hollands and supertartrate of potash, may be allowed for the drink. Regular exercise, such as the patient can bear, (the limbs being properly supported, especially by a well-contrived laced stocking,) ought to be enjoined, or diligent friction of the skin, particularly of the affected parts, employed when the tumefaction is usually least, namely, in the morning. The cold bath duly regulated may also, when the patient is convalescent, materially contribute to obviate a relapse.

Anaspa'sis. (From *ανα*, and *σπαω*, to draw together.) Hippocrates uses this word to signify a contraction of the stomach.

Ana'ssytos. (From *ανα*, upwards, and *σευομαι*, to agitate.) *Anassytus.* Driven forcibly upwards. Hippocrates applies this epithet to air rushing violently upwards, as in hysteric fits.

Anasta'ltica. (From *αναϛελλω*, to contract.) Styptic or refrigerating medicines.

Ana'stasis. (From *αναϛημι*, to cause to rise.) A recovery from sickness; a restoration of health. It likewise signifies a migration of humours, when expelled from one place and obliged to remove to another. *Hippocrates.*

ANASTOMO'SIS. (From *ανα*, through, and *ϛομα*, a mouth.) The communication of vessels with one another.

Anastomo'tica. (From *ανα*, through, and *ϛομα*, the mouth.) Medicines which open the pores and mouths of the vessels, as cathartics, diuretics, deobstruents, and sudorifics.

Ana'tes. (From *nates*, the buttocks.) A disease of the anus. *Festus*, &c.

ANA'TOMY. (*Ανατομια*, or *ανατομη*: from *ανα*, and *τεμνω*, to cut up.) *Anerotomy.* The dissection of the human body, to expose the structure, situation, and uses of every part.

Anatomy, comparative. Zootomy. The dissection of brutes, fishes, polypi, plants, &c. to illustrate, or compare them with the structure and functions of the human body.

Anatre'sis. (From *ανα*, and *τιτραω*, to perforate.) A perforation like that which is made upon the skull by trepanning. *Galen.*

Anatri'be. (From *ανατριβω*, to rub.) Friction all over the body.

Anatri′psis. The same. *Moschion de Morb. Mulieb.* and *Galen.*

Ana′tris. *Antaris.* Mercury. *Ruland.*

Ana′tron. (Arab. A lake in Egypt, where it was produced.) Soda, or fixed mineral alkali.

Ana′trope. (From *ανατρεπω*, to subvert.) *Anatrophe. Anatropha.* A relaxation, or subversion of the stomach, with loss of appetite and nausea. Vomiting. Indigestion. *Galen.*

Ana′trum. Soda.

Anau′dia. (From *α*, priv. and *αυδη*, the speech.) Dumbness; privation of voice; catalepsia. *Hippocrates.*

Ana′xyris. (From *αναξυρις*, the sole.) The herb sorrel; so called because its leaf is shaped like the sole of the shoe.

A′ncha. (Arab. to press upon, as being the support of the body.) The thigh. *Avicenna, Forestius,* &c.

A′nchilops. (From *αγχι*, near, and *ωψ*, the eye.) A disease in the inward corner of the eye, called also Ægilops. An incipient fistula lachrymalis.

Anchora′lis proce′ssus. (*Anchoralis*; from *αγκων*, the elbow.) See *Coracoid process.*

Anchovy pear. This fruit, the produce of the *Grias cauliflora* of Linnæus, is eaten by the inhabitants of Jamaica, as a pleasant and refrigerant fruit.

ANCHU′SA. (From *αγχειν*, to strangle; from its supposed constringent quality; or, as others say, because it strangles serpents.) Alkanet.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

2. The name in some pharmacopœias for the alkanet root and bugloss.

Anchusa officinalis. The officinal bugloss. *Anchusa foliis lanceolatis strigosis, spicis secundis imbricatis, calycibus quinque partitis,* of Linnæus: it was formerly esteemed as a cordial in melancholic and hypochondriacal diseases. It is seldom used in modern practice, and then only as an aperient and refrigerant. In some pharmacopœias it is called *Buglossa. Buglossum angustifolium majus. Buglossum vulgare majus. Buglossum sativum.*

Anchusa tinctoria. The systematic name for the anchusa or alkanna of the pharmacopœias. This plant grows wild in France, but is cultivated in our gardens. The root is externally of a deep purple colour. To oil, wax, turpentine, and alkohol, it imparts a beautiful deep red colour, for which purpose it is used. Its medicinal properties are scarcely perceptible.

A′nchyle. See *Ancyle.*

Anchylomeri′sma. (From *αγχυλομαι*, to bend.) Sagar uses this term to express a concretion, or growing together of the soft parts.

ANCHYLO′SIS. (From *αγχυλομαι*, to bend.) A stiff joint.

It is divided into the *true* and *spurious*, according as the motion is entirely or but partly lost. This state may arise from various causes, as tumefaction of the ends of the bones, caries, fracture, dislocation, &c. also dropsy of the joint, fleshy excrescences, aneurisms, and other tumours. It may also be owing to the morbid contraction of the flexor muscles, induced by the limb being long kept in a particular position, as a relief to pain, after burns, mechanical injuries, &c. The rickets, white swellings, gout, rheumatism, palsy, from lead particularly, and some other disorders, often lay the foundation of anchylosis: and the joints are very apt to become stiff in advanced life. Where the joint is perfectly immoveable, little can be done for the patient; but in the spurious form of the complaint, we must first endeavour to remove any cause mechanically obstructing the motion of the joint, and then to get rid of the morbid contraction of the muscles. If inflammation exist, this must be first subdued by proper means. Where extraneous matters have been deposited, the absorbents must be excited to remove them: and where the parts are preternaturally rigid, emollient applications will be serviceable. Fomentations, gentle friction of the joint and of the muscles, which appear rigid, with the camphor liniment, &c. continued for half an hour or more two or three times a day; and frequent attempts to move the joint to a greater extent, especially by the patient exerting the proper muscles, not with violence, but steadily for some time, are the most successful means: but no rapid improvement is to be expected in general. Sometimes in obstinate cases, rubbing the part with warm brine occasionally, or applying stimulant plasters of ammoniacum, &c. may expedite the cure: and in some instances, particularly as following rheumatism, pumping cold water on the part every morning has proved remarkably beneficial. Where there is a great tendency to contraction of the muscles, it will be useful to obviate this by some mechanical contrivance. It is proper to bear in mind, where from the nature of the case, complete anchylosis cannot be prevented, that the patient may be much less inconvenienced by its being made to occur in a particular position; that is in the upper extremities generally a bent, but in the hip or knee an extended one.

A′nci. Those who have a distorted elbow.

Ancirome′le. See *Ancylomele.*

A′ncinar. Borax.

A′ncon. (From *αγκαζομαι*, to embrace; *απο τȣ αγκεισθαι ἑτερῳ οϛεῳ το οϛεον*: because the bones meeting and there uniting, are folded one into another.) The elbow.

ANCONE′US. (*Anconeus*, sc. *musculus;* from αγκων, the elbow.) *Anconeus minor* of Winslow. *Anconeus vel cubitalis Riolani* of Douglas. A small triangular muscle, situated on the back part of the elbow. It arises from the ridge, and from the external condyle of the humerus, by a thick, strong, and short tendon: from this it becomes fleshy, and, after running about three inches obliquely backwards, it is inserted by its oblique fleshy fibres into the back part or ridge of the ulna. Its use is to extend the fore-arm.

Ancone′us exte′rnus. See *Triceps extensor cubiti.*

Ancone′us inte′rnus. See *Triceps extensor cubiti.*

Ancone′us ma′jor. See *Triceps extensor cubiti.*

Ancone′us mi′nor. See *Anconeus.*

Anconoid process. *Processus anconoideus.* (From αγκων, the elbow.) A process of the cubit. See *Ulna.*

A′ncter. (Αγκτηϱ, a bond, or button.) A fibula, or button, by which the lips of wounds are held together. *Gorræus.*

Ancteria′smus. (From αγκτηϱ, a button.) The operation of closing the lips of wounds together by loops, or buttons. *Galen.*

Ancu′bitus. A disease of the eyes with a sensation of sand. *Joh. Anglic. Ros. Ang.*

A′ncyle. (From αγκυλος, crooked.) A species of contraction, called a stiff joint. *Galen.*

ANCYLOBLE′PHARON. (From αγκυλη, a hook, and βλεφαϱον, an eyelid.) A disease of the eye, by which the eyelids are closed together. *Aëtius.*

ANCYLOGLO′SSUM. (From αγκυλη, a hook, and γλωσσα, the tongue.) *Ancylion* of Ægineta. A contraction of the frænulum of the tongue. Tongue-tied.

Ancylome′le. (From αγκυλος, crooked, and μηλη, a probe.) A crooked probe, or a probe with a hook. *Galen, &c.*

Ancylo′sis. See *Anchylosis.*

Ancylo′tomus. (From αγκυλη, a hook, and τεμνω, to cut.) A crooked chirurgical knife, or bistoury. A knife for loosening the tongue. This instrument is no longer in use. *Ægineta, &c.*

A′ncyra. (Αγκυϱα, an anchor.) A chirurgical hook. Epicharmus uses this word for the membrum virile, according to Gorræus.

Ancyroi′des. (From αγκυϱα, an anchor, and ειδος, a likeness.) A process of the scapula was so called, from its likeness to the beak of an anchor. It is the coracoid process. See *Scapula.*

Ancyrome′le. See *Ancylomele.*

Andi′ra. A tree of Brazil, the fruit of which is bitter and astringent, and used as a vermifuge.

Andranato′mia. *Andranatome.* (From ανηϱ, a man, and τεμνω, to cut.) The dissection of the human body, particularly of the male. *M. Aur. Severinus, Zootome Democrit.*

Andrapodocape′lus. (From ανδϱοποδον, a slave, and καπηλος, a dealer.) A crimp. Galen calls by this name the person whose office it was to anoint and slightly to wipe the body, to cleanse the skin from foulness.

A′ndria. (From ανηϱ, a man.) An hermaphrodite. *Bonnet.*

Androcœte′sis. (From ανηϱ, a man, and κοιτεω, to cohabit with.) The venereal act; or the infamous act of sodomy. *Moschion, &c.*

Andro′gynus. (From ανηϱ, a man, and γυνη, a woman.) An effeminate person. *Hipp.* An hermaphrodite.

Andro′machus, of *Crete*, was physician to the Emperor Nero. He invented a composition, supposed to be an antidote against poison, called after him, Theriaca Andromachi, which he dedicated to that Emperor in a copy of Greek verses still preserved. This complicated preparation long retained its reputation, but is now deservedly abandoned.

Andro′nion. *Andronium.* A kind of plaster used by Ægineta for carbuncles, invented by Andron.

Andropogon Schænanthus, *Juncus odoratus. Fœnum camelorum. Juncus aromaticus.* The systematic name of the Camel-hay, or Sweet rush. The dried plant is imported into this country from Turkey and Arabia. It has an agreeable smell, and a warm, bitterish, not unpleasant taste. It was formerly employed as a stomachic and deobstruent.

Andro′tomia. *Androtome.* Human dissection, particularly of the male.

Andry, *Nicholas*, a physician, born at Lyons in 1658. He was made professor of medicine at Paris in 1701, and lived to the age of 84. Besides a Treatise on Worms, and other minor publications, and contributions in the Medical and Philosophical Journals, he was author of a work, still esteemed, called "Orthopedie," or the art of preventing and removing deformities in children; which he proposed to effect by regimen, exercise, and various mechanical contrivances.

Ane′bium. (From αναβαινω, to ascend.) The herb alkanet, so called from its quick growth.

Aneile′sis. (From ανειλεω, to roll up.) *Aneilema.* An involution of the guts, such as is caused by flatulence and gripes. *Hippocrates.*

Ane′mia. (From ανεμος, wind.) Flatulence.

ANE′MONE. (From ανεμος, wind; so named, because it does not open its flowers till blown upon by the wind.) The wind flower. The name of a genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Polygynia.*

Ane′mone hepa′tica. The systematic name for the *hepatica nobilis* of the pharmacopœias. *Herba trinitatis.* Hepatica, or herb trinity. This plant possesses mildly adstringent and corroborant virtues, with which intentions infusions of it have been drank as tea, or the powder of the dry leaves given, to the quantity of half a spoonful at a time.

Anemone meadow. See *Anemone pratensis.*

Ane′mone nemoro′sa. The systematic name of the *ranunculus albus* of the pharmacopœias. The bruised leaves and flowers are said to cure tinea capitis applied to the part. The inhabitants of Kamskatka, it is believed, poison their arrows with the root of this plant.

Ane′mone prate′nsis. The systematic name for the *Pulsatilla nigricans* of the pharmacopœias. This plant, *Anemone pedunculo involucrato, petalis apice reflexis, foliis bipinnatis,* of Linnæus: has been received into the Edinburgh pharmacopœia upon the authority of Baron Stoerck, who recommended it as an effectual remedy for most of the chronic diseases affecting the eye, particularly amaurosis, cataract, and opacity of the cornea, proceeding from various causes. He likewise found it of great service in venereal nodes, nocturnal pains, ulcers, caries, indurated glands, suppressed menses, serpiginous eruptions, melancholy and palsy. The plant, in its recent state, has scarcely any smell; but its taste is extremely acrid, and, when chewed, it corrodes the tongue and fauces.

Anence′phalus. (From *α*, priv. and *εγκεφαλος*, the brain.) A monster without brains. Foolish. *Galen de Hippocrate.*

A′neos. A loss of voice and reason.

Anepithy′mia. (From *α*, priv. and *επιθυμια*, desire.) Loss of appetite.

A′neric. *Anerit.* Sulphur vivum.

A′nesis. (From *ανιημι*, to relax.) A remission, or relaxation, of a disease, or symptom. *Aëtius,* &c.

Ane′sum. See *Anisum.*

ANE′THUM. (*Ανηθον*: from *ανευ*, afar, and *θεω*, to run; so called because its roots run out a great way.) Fennel, dill, anet.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.*

2. The pharmacopœial name of the common dill, or anet.

Ane′thum fœni′culum. The systematic name for the *fœniculum* of the shops. Sweet fennel, *Anethum fœniculum, fructibus ovatis* of Linnæus. The seeds and roots of this indigenous plant are directed by the colleges of London and Edinburgh. The seeds have an aromatic smell, and a warm sweetish taste, and contain a large proportion of essential oil. They are stomachic and carminative. The root has a sweet taste, but very little aromatic warmth, and is said to be pectoral and diuretic.

Ane′thum grave′olens. The systematic name for the *Anethum* of the shops. *Anethum fructibus compressis,* of Linnæus. This plant is a native of Spain, but cultivated in several parts of England. The seeds of dill are directed for use by the London and Edinburgh Pharmacopœias: they have a moderately warm, pungent taste, and an aromatic, but sickly smell. There is an essential oil, and a distilled water, prepared from them, which are given in flatulent colics and dyspepsia. They are also said to promote the secretion of milk.

Ane′tica. (From *ανιημι*, to relax.) Paregorics; medicines which assuage pain, according to Andr. Tiraquell.

ANEURI′SMA. (*-matis,* neut. *Ανευϱυσμα*, from *ανευϱυνω*, to dilate.) An aneurism. A preternatural tumour formed by the dilatation of an artery. A genus of disease ranked by Cullen in the class *locales,* and order *tumores.* There are three species of aneurism: 1. The *true aneurism, aneurisma verum,* which is known by the presence of a pulsating tumour. The artery either seems only enlarged at a small part of its tract, and the tumour has a determinate border, or it seems dilated for a considerable length, in which circumstance the swelling is oblong, and loses itself so gradually in the surrounding parts, that its margin cannot be exactly ascertained. The first, which is the most common, is termed *circumscribed true aneurism;* the last, the *diffused true aneurism.* The symptoms of the circumscribed true aneurism, take place as follows: the first thing the patient perceives, is an extraordinary throbbing in some particular situation, and, on paying a little more attention, he discovers there a small pulsating tumour, which entirely disappears when compressed, but returns again as soon as the pressure is removed. It is commonly unattended with pain or change in the colour of the skin. When once the tumour has originated, it continually grows larger, and at length attains a very considerable size. In proportion as it becomes larger, its pulsation becomes weaker, and, indeed, it is almost quite lost, when the disease has acquired much magnitude. The diminution of the pulsation has been ascribed to the coats of the artery losing their dilatable and elastic quality, in proportion as they are distended and indurated; and, consequently, the aneurismal sac being no longer capable of an alternate diastole and systole from the action of the heart. The fact is also imputed to the coagulated blood, deposited on the inner surface of the sac, particularly in large aneurisms, in which some of the blood is always interrupted in its motion. In true aneurisms, however, the blood does not coagulate so soon, nor so often as in false ones. Whenever such coagulated blood lodges in the sac, pressure can only produce a partial disappearance of the swelling. In proportion as the aneurismal sac grows larger, the communication into the artery beyond the tumour is lessened. Hence in this state, the pulse below the swelling becomes weak and small, and the limb frequently cold and œdematous. On dissection, the lower continuation of the artery is found preternaturally small, and contracted. The pressure of the tumour on the adjacent parts, also produces a variety of symptoms, ulcerations, caries, &c. Sometimes an accidental contusion, or concussion, may detach a piece of coagulum from the inner surface of the cyst, and the circulation through the sac be obstructed by it. The coagulum may possibly be impelled quite into the artery below, so as to induce important changes. The danger of an aneurism arrives when it is on the point of bursting, by which occurrence the patient usually bleeds to death; and this sometimes happens in a few seconds. The fatal event may generally be foreseen, as the part about to give way, becomes particularly tense, elevated, thin, soft, and of a dark purple colour. 2. The false or spurious aneurism, *aneurisma spurium*, is always owing to an aperture in the artery, from which the blood gushes into the cellular substance. It may arise from an artery being lacerated in violent exertions: but the most common occasional cause is a wound. This is particularly apt to occur at the bend of the arm, where the artery is exposed to be injured in attempting to bleed. When this happens, as soon as the puncture has been made, the blood gushes out with unusual force, of a bright scarlet colour, and in an irregular stream, corresponding to the pulsation of the artery. It flows out, however, in an even and less rapid stream when pressure is applied higher up than the wound. These last are the most decisive marks of the artery being opened; for blood often flows from a vein with great rapidity, and in a broken current, when the vessel is very turgid and situated immediately over the artery, which imparts its motion to it. The surgeon endeavours precipitately to stop the hæmorrhage by pressure; and he commonly occasions a *diffused false aneurism*. The external wound in the skin is closed, so that the blood cannot escape from it; but insinuates itself into the cellular substance. The swelling thus produced is uneven, often knotty, and extends upwards and downwards, along the tract of the vessel. The skin is also usually of a dark purple colour. Its size increases as long as the internal hæmorrhage continues, and, if this should proceed above a certain pitch, mortification of the limb ensues. 3. The *varicose aneurism, aneurisma varicosum*; this was first described by Dr. W. Hunter. It happens when the brachial artery is punctured in opening a vein: the blood then rushes into the vein, which becomes varicose. Aneurisms may happen in any part of the body, except the latter species, which can only take place where a vein runs over an artery. When an artery has been punctured, the tourniquet should be applied, so as to stop the flow of blood by compressing the vessel above; then the most likely plan of obviating the production of spurious aneurism appears to be applying a firm compress immediately over the wound, and securing it by a bandage, or in any other way, so as effectually to close the orifice, yet not prevent the circulation through other vessels; afterwards keeping the limb as quiet as possible, enjoining the antiphlogistic regimen, and examining daily that no extravasation has happened, which would require the compress being fixed more securely, previously applying the tourniquet, and pressing the effused blood as much as possible into the vessel. If there should be much coldness or swelling of the limb below, it will be proper to rub it frequently with some spirituous or other stimulant embrocation. It is only by trial that it can be certainly determined when the wound is closed; but always better not to discontinue the pressure prematurely. The same plan may answer, when the disease has already come on, if the blood can be entirely, or even mostly, pressed into the artery again; at any rate by determining the circulation on collateral branches it will give greater chance of success to a subsequent operation. There is another mode, stated to have sometimes succeeded even when there was much coagulated blood; namely making strong pressure over the whole limb, by a bandage applied uniformly, and moistened to make it sit closer, as well as to obviate inflammation; but this does not appear so good a plan, at least in slighter cases. If however the tumour be very large, and threatens to burst, or continues spreading, the operation should not be delayed. The tourniquet being applied, a free incision is to be made into the tumour, the extravasated blood removed, and the artery tied both above and below the wound, as near to it as may be safe; and if any branch be given off between, this must be also secured. It is better not to make the ligatures tighter, than may be necessary to stop the flow of blood; and to avoid including any nerve if possible. Sometimes where extensive suppuration or caries has occurred, or gangrene is to be apprehended, amputation will be necessary: but this must not be prematurely resolved upon, for often after several weeks the pulse has returned in the limb below. In the true aneurism, when small and recent, cold and astringent applications are sometimes useful; or making pressure on the tumour, or on the artery above, may succeed; otherwise an operation becomes necessary to save the patient's life; though unfortunately it oftener fails in this than in the spurious kind; gangrene ensuing, or hæmorrhage; this chiefly arises from the arteries being often extensively diseased, so that they are more likely to give way, and there is less vital power in the limb. A great improvement has been made in the mode of operating in these cases by Mr. John Hunter, and other modern surgeons, namely, instead of proceeding as already explained in the spurious aneurism, securing the artery some way above, and leaving the rest in a great measure to the powers of nature. It has been now proved by many instances, that when the current of the blood is thus interrupted, the tumour will cease to enlarge, and often be considerably diminished by absorption. There is reason for believing too, that the cures effected spontaneously, or by pressure, have been usually owing to the trunk above being obliterated. There are many obvious advantages in this mode of proceeding; it is more easy, sooner performed, and disorders the system less, particularly as you avoid having a large unhealthy sore to be healed; besides there is less probability of the vessel being diseased at some distance from the tumour. In the popliteal aneurism, for example, the artery may be secured rather below the middle of the thigh, where it is easily come at. The tourniquet therefore being applied, and the vessel exposed, a strong ligature is to be passed round it; or, which is perhaps preferable, two ligatures a little distant, subsequently cutting through the artery between them, when the two portions contract among the surrounding flesh. It is proper to avoid including the nerve or vein, but not unnecessarily detach the vessel from its attachments. For greater security one end of each ligature, after being tied, may be passed through the intercepted portion of artery, that they may not be forced off. Then the wound is to be closed by adhesive plaster, merely leaving the ends of the ligatures hanging out, which will after some time come away. However it must be remembered that hæmorrhage is liable to occur; when this happens, even three or four weeks after the operation; so that proper precautions are required, to check it as soon as possible; likewise the system should be lowered previously, and kept so during the cure. When a true aneurism changes into the spurious form, which is known by the tumour spreading, becoming harder, and with a less distinct pulsation, the operation becomes immediately necessary. When an aneurism is out of the reach of an operation, life may be prolonged by occasional bleeding, a spare diet, &c.; and when the tumour becomes apparent externally, carefully guarding it from injury. In the varicose aneurism an operation will be very seldom if ever required, the growth of the tumour being limited.

Aneuri′sma spu′rium. See *Aneurisma.*

Aneuri′sma varico′sum. See *Aneurisma.*

Aneuri′sma ve′rum. See *Aneurisma.*

Ane′xis. (From ανεχω, to project.) A swelling, or protuberance.

ANGEIOLO′GIA. (From αγγειον, a vessel, and λογος, a discourse.) A dissertation, or reasoning, upon the vessels of the body.

ANGEIO′TOMY. (From αγγειον, a vessel, and τεμνω, to cut.) The dissection of the blood-vessels of an animal body; also the opening of a vein, or an artery.

Angeioti′smus. (From αγγειον, a vessel, and τεμνω, to cut.) A skiful dissector of the vessels.

ANGE′LICA. (So called from its supposed angelic virtues.) Angelica. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.*

2. The pharmacopœial name of the garden-angelica.

Ange′lica archange′lica. The systematic name for the *angelica* of the shops. *Angelica foliorum impari lobato* of Linnæus. A plant, a native of Lapland, but cultivated in our gardens. The roots of angelica have a fragrant, agreeable smell, and a bitterish, pungent taste. The stalk, leaves, and seeds, which are also directed in the pharmacopœias, possess the same qualities, though in an inferior degree. Their virtues are aromatic and carminative. A sweetmeat is made, by the confectioners, of this root, which is extremely agreeable to the stomach, and is surpassed only by that ginger.

Angelica, garden. See *Angelica.*

Ange′lica sati′va. See *Angelica sylvestris.*

Ange′lica sylve′stris. *Angelica sativa.* Wild angelica. *Angelica foliis æqualibus ovato-lanceolatis serratis*, of Linnæus. This species of angelica possesses similar properties to the garden species, but in a much inferior degree. It is only used when the latter cannot be obtained. The seeds, powdered and put in the hair, kill lice.

Angelica, wild. See *Angelica sylvestris.*

Angeli′næ co′rtex. The tree from which this bark is procured is a native of Grenada. It has been recommended as an anthelmintic for children.

Angeloca′cos. Myrobalans, or purging Indian plums.

A′ngi. (From *angor*, anguish; because of their pain.) Buboes in the groin. *Fallopius de Morbo Gallico.*

Angiglo′ssus. (From αγκυλη, a hook, and γλωσσα, the tongue.) A person who stammers.

ANGI′NA. (From αγχω, to strangle; because it is often attended with a sense of strangulation.) A sore throat. See *Cynanche.*

Angi′na maligna. See *Cynanche maligna.*

Angi′na parotide′a. See *Cynanche parotidea.*

ANGI'NA PE'CTORIS. *Syncope anginosa* of Dr. Parry. An acute constrictory pain at the lower end of the sternum, inclining rather to the left side, and extending up into the left arm, accompanied with great anxiety. Violent palpitations of the heart, laborious breathings, and a sense of suffocation, are the characteristic symptoms of this disease. — It is found to attack men much more frequently than women, particularly those who have short necks, who are inclinable to corpulency, and who, at the same time, lead an inactive and sedentary life. Although it is sometimes met with in persons under the age of twenty, still it more frequently occurs in those who are between forty and fifty. In slight cases, and in the first stage of the disorder, the fit comes on by going up-hill, up-stairs, or by walking at a quick pace after a hearty meal; but as the disease advances, or becomes more violent, the paroxysms are apt to be excited by certain passions of the mind; by slow walking, by riding on horseback, or in a carriage; or by sneezing, coughing, speaking, or straining at stool. In some cases, they attack the patient from two to four in the morning, or whilst sitting or standing, without any previous exertion or obvious cause. On a sudden, he is seized with an acute pain in the breast, or rather at the extremity of the sternum, inclining to the left side, and extending up into the arm, as far as the insertion of the deltoid muscle, accompanied by a sense of suffocation, great anxiety, and an idea that its continuance, or increase, would certainly be fatal. In the first stage of the disease, the uneasy sensation at the end of the sternum, with the other unpleasant symptoms, which seemed to threaten a suspension of life by a perseverance in exertion, usually go off upon the person's standing still, or turning from the wind; but, in a more advanced stage, they do not so readily recede, and the paroxysms are much more violent. During the fit, the pulse sinks in a greater or less degree, and becomes irregular; the face and extremities are pale, and bathed in a cold sweat, and, for a while, the patient is perhaps deprived of the powers of sense and voluntary motion. The disease having recurred more or less frequently during the space of some years, a violent attack at last puts a sudden period to his existence. Angina pectoris is attended with a considerable degree of danger; and it usually happens that the person is carried off suddenly. It mostly depends upon an ossification of the coronary arteries, and then we can never expect to effect a radical cure. During the paroxysms, considerable relief is to be obtained from fomentations, and administering powerful antispasmodics, such as opium and æther combined together. The application of a blister to the breast is likewise attended sometimes with a good effect. As the painful sensation at the extremity of the sternum often admits of a temporary relief, from an evacuation of wind by the mouth, it may be proper to give frequent doses of carminatives, such as peppermint, carraway, or cinnamon water. Where these fail in the desired effect, a few drops of ol. anisi, on a little sugar, may be substituted.

With the view of preventing the recurrence of the disorder, the patient should carefully guard against passion, or other emotions of the mind: he should use a light, generous diet, avoiding every thing of a heating nature; and he should take care never to overload the stomach, or to use any kind of exercise immediately after eating. Besides these precautions, he should endeavour to counteract obesity, which has been considered as a predisposing cause; and this is to be effected most safely by a vegetable diet, moderate exercise at proper times, early rising, and keeping the body perfectly open. It has been observed that angina pectoris is a disease always attended with considerable danger, and, in most instances, has proved fatal under every mode of treatment. We are given, however, to understand, by Dr. Macbride, that of late, several cases of it have been treated with great success, and the disease radically removed, by inserting a large issue in each thigh. These, therefore, should never be neglected. In one case, with a view of correcting, or draining off the irritating fluid, he ordered, instead of issues, a mixture of lime-water with a little of the spirituous juniperi comp., and an alterative proportion of Huxham's antimonial wine, together with a plain, light, perspirable diet. From this course the patient was soon apparently mended; but it was not until after the insertion of a large issue in each thigh, that he was restored to perfect health.

Angi'na tonsilla'ris. See *Cynanche tonsillaris*.

Angi'na trache'alis. See *Cynanche trachealis*.

ANGIOLO'GIA. (From αγγειον, a vessel, and λογος, a discourse.) The doctrine of the vessels of the human body.

A'nglicus su'dor. (From *Anglia*, England, and *sudor*, sweat.) The sweating sickness. *Sennertus*.

Ango'lam. A very tall tree of Malabar, possessing vermifuge powers.

Ango'ne. (From αγχω, to strangle.) A nervous sort of quinsy, or hysteric suffocation, where the fauces are contracted and stopped up without inflammation.

A'ngor. Intense bodily pain. *Galen*.

A'ngos. (Αγγος, a vessel.) A vessel; a collection of humours.

ANGUSTU'RÆ CORTEX. Angustura bark. See *Cusparia*.

Anhela'tio. (From *anhelo*, to breathe with difficulty.) *Anhelitus*. Shortness of breathing.

Anice′ton. (From α, priv. and νικη, victory.) A name of a plaister invented by Crito, and so called because it was thought an infallible or invincible remedy for achores, or scald-head. It was composed of litharge, alum, and turpentine, and is described by Galen.

A′NIMA. The thinking principle.

A′nima a′loës. Refined aloes.

A′nima articulo′rum. Hermodactylus.

A′nima he′patis. Sal martis.

A′nima pulmo′num. The soul of the lungs. A name given to saffron, on account of its use in asthmas.

A′nima rhaba′rbari. The best rhubarb.

A′nima satu′rni. A preparation of lead.

A′nima ve′neris. A preparation of copper.

ANIMAL. An organized body endowed with life and voluntary motion.

Animal actions. *Actiones animales.* Those actions, or functions, are so termed, which are performed through the means of the mind. To this class belong the external and internal senses, the voluntary action of muscles, voice, speech, watching, and sleep.

Animal heat. Heat is essentially necessary to life. That of a man in health is about 98 of Fahrenheit. It appears to depend upon the decomposition of the air in the lungs. See *Respiration*.

Animal oil. Oleum animale. An empyreumatic oil, obtained from the bones of animals, recommended as an anodyne and antispasmodic.

A′nime gu′mmi. The substance which bears this name in the shops is a resin, the produce of the *Hymenæa courbaril* of Linnæus. It is seldom ordered in the practice of the present day, and is only to be met with in the collections of the curious.

A′nimi deli′quium. (From *animus*, the mind, and *delinquo*, to leave.) Fainting. See *Syncope*.

A′nimus. This word is to be distinguished from *anima*; the former expresses the faculty of reasoning, and the latter the being in which that faculty resides.

Anin′ga. A root which grows in the Antilles islands, and is used by sugar-bakers for refining their sugar.

Anisca′lptor. (From *anus*, the breech, and *scalpo*, to scratch.) The latissimus dorsi is so called, because it is the muscle chiefly instrumental in performing this office. *Bartholin.*

Aniso′tachys. (From ανισος, unequal, and ταχυς, quick.) A quick and unequal pulse. *Gorræus.*

ANI′SUM. (From α, neg. and ισος, equal.) Anise. See *Pimpinella*.

Ani′sum sine′nse. } See *Illicium*
Anis′um stellatum. } *Anisatum*.

Ani′sum vulgare. See *Pimpinella*.

Annue′ntes. (From *annuo*, to nod.) Some muscles of the head were formerly so called, because they perform the office of nodding, or bending the head downwards. *Cowper, &c.*

Annular. (*Annularis.*) Like a ring; thus, annular bone, &c.

Annular bone. *Circulus osseus.* A ring-like bone placed before the cavity of the tympanum in the fœtus.

Annular cartilage. See *Cartilago Cricoidea.*

Annula′ris di′gitus. The ring-finger. The one between the little and middle fingers.

Annula′ris proce′ssus. See *Pons varolii.*

A′NNULUS ABDO′MINIS. The abdominal ring. An oblong tendinous opening in each groin, through which the spermatic chord in men, and the round ligament of the uterus in women, pass. It is through this aperture that the abdominal viscera fall in that species of hernia, which is called bubonocele. See *Obliquus externus abdominis.*

A′no. (Ανω, upwards; in opposition to κατω, downwards.) Upwards.

Anocatha′rtica. (From ανω, upwards, and καθαιρω, to purge.) Emetics: medicines which purge upwards.

Anochei′lon. (From ανω, upwards, and χειλος, the lip.) The upper lip.

Ano′dia. (From α, neg. and οδος, the way.) Hippocrates uses this word for inaccuracy and irregularity in the description and treatment of a disease.

Ano′dyna. See *Anodynes.*

ANODYNES. (*Anodyna*, sc. *medicamenta.* From α, priv. and ωδυνη, pain.) Those medicines are so termed which ease pain and procure sleep. They are divided into three sorts; paregorics, or such as assuage pain; hypnotics, or such as relieve by procuring sleep; and narcotics, or such as ease the patient by stupifying him.

Ano′dynum minera′le. Sal prunella.

Ano′dynum martia′le. Ferrum ammoniatum precipitated from water by potash.

Anomalous. This term is often applied to those diseases whose symptoms do not appear with that regularity which is generally observed in diseases. A disease is also said to be anomalous, when the symptoms are so varied as not to bring it under the description of any known affection.

Ano′mphalos. (From α, priv. and ομφαλος, the navel.) *Anomphalus.* Without a navel.

Ano′nymus. (From α, priv. and ονομα, name.) Nameless; it was formerly applied to the cricoid muscle.

Ano′rchides. (From α, priv. and ορχις, the testicle.) Children are so termed which come into the world without testicles. This is a very common occurrence. The testicles of many male infants at the time of birth are within the abdomen. The time of their descent is very uncertain, and instances have occurred where they have not reached the scrotum at the age of ten or fifteen.

ANORE′XIA. (From *α*, priv. and *ορεξις*, appetite.) A want of appetite, without loathing of food. Cullen ranks this genus of disease in the class *locales*, and order *dysorexiæ*; he believes it to be generally symptomatic, but enumerates two species, viz. the *anorexia humoralis*, and the *anorexia atonica*. See *Dyspepsia*.

ANO′SMIA. (From *α*, neg. and *οζω*, to smell.) A loss of the sense of smelling. This genus of disease is arranged by Cullen in the order *locales*, and order *dysæthesiæ*. When it arises from a disease of the Schneiderian membrane, it is termed *anosmia organica*; and when from no manifest cause, *anosmia atonica*.

A′NSER DOME′STICUS. The tame goose. The flesh of this bird is somewhat similar to that of the duck, and requires the assistance of spirituous and stimulating substances, to enable the stomach to digest it. Both are very improper for weak stomachs.

ANSERI′NA. (From *anser*, a goose; so called, because geese eat it.) See *Potentilla*.

ANTACIDS. (*Antacida*, sc. *medicamenta*. From *αντι*, against, and *acidus*, acid.) Remedies which obviate acidity in the stomach. Their action is purely chemical, as they merely combine with the acid present, and neutralize it. They are only palliatives, the generation of acidity being to be prevented by restoring the tone of the stomach and its vessels. Dyspepsia and diarrhœa are the diseases in which they are employed. The principal antacids in use are the alkalies; e. g. Liquoris potassæ, gutt. xv. or from 5 to 15 gr. of subcarbonate of potash, or soda dissolved in water. The solution of soda, called double soda-water, or that of potash supersaturated with carbonic acid, is more frequently used, as being more pleasant. Ammonia has been recommended as preferable to every other antacid, from 10 to 20 drops of the liquor ammoniæ in a cupful of water. The liquor calcis, or lime water, is likewise used to correct acidity, two or three ounces being taken occasionally. Creta præparata alone, or with the addition of a small quantity of any aromatic — chelæ cancrorum præparatæ; magnesia also and its carbonate, are used for the same purpose.

Antagonist muscles. Counteracting muscles, or those muscles which have opposite functions. Such are the flexor and extensor of any limb, the one of which contracts it, the other stretches it out; and also the abductors and adductors. Solitary muscles are those without any antagonist, as the heart, &c.

Anta′lgica. (From *αντι*, against, and *αλγος*, pain.) Anodynes. Remedies which relieve pain.

Anta′lkalines. (From *αντι*, against, and *alkali*, an alkali.) Medicines which possess the power of neutralizing alkalis. All the acids are of this class.

Antaphrodisi′aca. (From *αντι*, against, and *Αφροδιτη*, Venus.) Anti-venereals, or medicines which extinguish amorous desires. *Wedel. Amen. Med.*

Antaphrodi′tica. The same.

Antapo′dosis. (From *ανταποδιδωμι*, to reciprocate.) A vicissitude, or return of the paroxysm of fevers. *Hippocrates.* Called by Galen *epidosis*.

Antaris. Mercury.

Antarthri′tica. (From *αντι*, against, and *αρθριτις*, the gout.) Medicines which relieve or repel the gout.

Antasthma′tica. (From *αντι*, against, and *ασθμα*, an asthma.) Remedies against asthma.

Antatro′phica. (From *αντι*, against, and *ατροφια*, a consumption.) Medicines which relieve consumption.

Anteche′sis. (From *ἀντεχομαι*, to resist.) A violent stoppage in the bowels, which resists all efforts to remove it. *Hippocrates.*

Antela′bium. (From *ante*, before, and *labium*, a lip.) The extremity of the lip.

Ante′mbasis. (From *αντι*, mutually, and *εμβαινω*, to enter.) A coalescence, or union of bone. *Galen.*

Anteme′tica. (From *αντι*, against, and *εμεω*, to vomit.) Medicines which stop or prevent vomiting.

Antenea′smus. (From *αντι*, against, and *τεινεσμος*, implacable.) That species of madness in which the patient endeavours to destroy himself.

Antephia′ltica. (From *αντι*, against, and *εφιαλτης*, the night-mare.) Medicines which prevent the night-mare.

Antepile′ptica. (From *αντι*, against, and *επιληψις*, the epilepsy.) Remedies against the epilepsy, and other convulsive disorders.

ANTE′RIOR AU′RIS. One of the common muscles of the ear, situated before the external ear. It arises thin and membranous, near the posterior part of the *zygoma*, and is inserted into a small eminence on the back of the helix, opposite to the concha, which it draws a little forwards and upwards.

ANTERIOR INTERCOSTAL NERVE. *Splanchnic nerve.* A branch of the great intercostal that is given off in the thorax.

Ante′rior ma′llei. See *Laxator tympani*.

Anthe′lix. See *Antihelix*.

Anthe′lmia. (From *αντι*, against, and *ελμινς*, a worm.) The herb Indian pink, or worm-grass, so called, because it was thought of great virtue in expelling worms. See *Spigelia Marilandica*.

ANTHELMINTICS. (*Anthelmintica*, sc. *medicamenta*; from αντι, against, and ελμινς, a worm.) Medicines which procure the evacuation of worms from the stomach and intestines. The greater number of them act mechanically, dislodging the worms, by the sharpness or roughness of their particles, or by their cathartic operation. Some seem to have no other qualities than those of powerful bitters, by which they either prove noxious to these animals, or remove that debility of the digestive organs, by which the food is not properly assimilated, or the secreted fluids poured into the intestines are not properly prepared; circumstances from which it has been supposed the generation of worms may arise. The principal medicines belonging to this class, are: Calomel, gamboge, Geoffræa inermis, tanacetum, polypodium filix mas, spigelia Marilandica, artemisia santonica, olea Europæa, stannum pulverisatum, ferri limaturæ, and dolichos pruriens: which see under their respective heads.

A′NTHEMIS. (*Anthemis, midis*; fœm. From ανθεω, *floreo*; because it bears an abundance of flowers.) Chamomile.

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*. Order, *Polygamia superflua*.

2. The name in the last London Pharmacopœia for chamomile. See *Anthemis nobilis*.

A′NTHEMIS CO′TULA. (*Cotula*, a dim. of *cos*, a whetstone; so called from its leaves resembling a whetstone.) The systematic name for the plant called *Cotula fœtida* in the pharmacopœias. *Chamæmelum fœtidum*. Mayweed. Stinking camomile. This plant, *Anthemis cotula*, of Linnæus: — *receptaculis conicis paleis setaceis, seminibus nudis*, has a very disagreeable smell; the leaves, a strong, acrid, bitterish taste; the flowers, however, are almost insipid. It is said to have been useful in hysterical affections, but is very seldom employed.

A′NTHEMIS NO′BILIS. The systematic name for the *chamæmelum* of the shops. *Chamæmelum nobile*. *Chamomilla romana*. *Euanthemon* of Galen. *Anthemis* of the last London pharmacopœia. Common chamomile. *Anthemis foliis pinnato-compositis linearibus acutis subvillosis*, of Linnæus. Both the leaves and flowers of this indigenuous plant have a strong though not ungrateful smell, and a very bitter, nauseous taste: but the latter are the bitterer, and considerably more aromatic. They possess tonic and stomachic qualities, and are much employed to restore tone to the stomach and intestines, and as a pleasant and cheap bitter. They have been long successfully used for the cure of intermittents, as well as of fevers of the irregular nervous kind, accompanied with visceral obstructions. The flowers have been found useful in hysterical affections, flatulent or spasmodic colics, and dysentery; but, from their laxative quality, Dr. Cullen tells us they proved hurtful in diarrhœas. A simple infusion is frequently taken to excite vomiting, or for promoting the operation of emetics. Externally they are used in the *decoctum pro fomento*, and are an ingredient in the *decoctum malvæ compositum*.

A′NTHEMIS PYRE′THRUM. The plant from which we obtain the pyrethrum of the pharmacopæias. *Buphthalmum creticum*. *Bellis montana putescens acris*. *Dentaria*. *Herba salivaris*. *Pes alexandrinus*. Spanish Chamomile. Pellitory of Spain. *Anthemis caulibus simplicibus unifloris decumbentibus, foliis pinnato-multifidis*, of Linnæus. This root, though cultivated in this country, is generally imported from Spain. Its taste is hot and acrid, its acrimony residing in a resinous principle. The antient Romans, it is said, employed the root of this plant as a pickle. In its recent state, it is not so pungent as when dried, and yet, if applied to the skin, it produces inflammation. Its qualities are stimulant; but it is never used, except as a masticatory, for relieving toothaches, rheumatic affections of the face, and paralysis of the tongue, in which it affords relief by stimulating the excretory ducts of the salival glands.

ANTHERA. (From ανθος, a flower.)

1. A compound medicine used by the antients; so called from its florid colour. *Galen*. *Ægineta*.

2. The male part of the fructification of plants.

ANTHOPHY′LLI. (From ανθος, a flower, and φυλλον, a leaf; so called from the fragrance of the flowers and the beauty of the leaves.) Cloves are so termed when they have been suffered to grow to maturity. *G. Bauhin Pin.*

A′NTHORA. (*Quasi antithora*, αντιθορα: from αντι, against, and θορα, monkshood; so called because it is said to counteract the effects of the thora or monkshood.) A species of Wolfsbane. See *Aconitum*.

A′NTHOS FLO′RES. The flowers of the *rosmarinus* are so termed in some pharmacopœias.

ANTHRA′CIA. See *Anthrax*.

A′NTHRAX. (From ανθϱαξ, a burning coal.) *Anthracia*. *Anthrocosia*. *Anthrocoma*. *Carbunculus*. An hard and circumscribed inflammatory tubercle like a boil, which sometimes forms on the cheek, neck, or back, and in a few days becomes highly gangrenous. It then discharges an extremely fœtid sanies from under the black core, which, like a burning coal, continues destroying the surrounding parts. It is supposed to arise from a peculiar miasma, is most common in warm climates, and often attends the plague.

ANTHRACO′SIS O′CULI. A red, livid,

burning, sloughy, very painful tumour, occurring on the eyelids. *Ægineta.*

Anthropogra'phia. (From ανθρωπος, a man, and γραφω, to write.) Description of man's structure.

ANTHROPOLO'GIA. (From ανθρωπος, a man, and λογος, a discourse.) The description of man.

Anthypno'tica. (From αντι, against, and υπνος, sleep.) Medicines which prevent sleep or drowsiness.

Anthypochondri'aca. (From αντι, against, and ὑποχονδρια, the hypochondria.) Medicines adapted to cure low-spiritedness or disorders of the hypochondria.

Anthyste'rica. (From αντι, against, and υστερα, the womb.) Uterines or medicines which relieve the hysteric passion. *Blancard.*

A'NTI. (Αντι, against.) There are many names compounded with this word, as *antiasthmatics, antihysterics, antidysenterics,* &c. which signify medicines against the asthma, hysterics, dysentery, &c.

Anti'ades. (From αντιαω, to meet.) The tonsils are so called, because they answer one another. The mumps. *Nic. Piso.*

Antia'gra. (From αντιας, a tonsil, and αγρα, a prey.) *Antiagri.* A tumour of the tonsils. *Ulpian, Roland,* &c.

Antiarthri'tica. See *Antarthritica.*

Anticache'ctica. (From αντι, against, and καχεξια, a chachexy.) Medicines against a cachexy, or bad habit of body.

Antica'rdium. (From αντι, against, or opposite, and καρδια, the heart.) The hollow at the bottom of the breast, commonly called scrobiculus cordis, or pit of the stomach.

Anticatarrha'lia. (From αντι, against, and καταῤῥος, a catarrh.) Medicines which relieve a catarrh.

Anticauso'tica. (From αντι, against, and καυσος, a burning fever.) Remedies against burning fevers. We read, in Corp. Pharm. of Junken, of a *syrupus anticausoticus.*

A'nticheir. (From αντι, against, and χειρ, the hand.) The thumb. *Galen.*

Anticne'mion. (From αντι, against, or opposite, and κνημη, the calf of the leg.) That part of the tibia which is bare of flesh, and opposite the calf of the leg. The shin-bone. *Galen.*

Antico'lica. (From αντι, against, and κωλικη, the colic.) Remedies against the colic.

Antidia'stole. (From αντι, against, and διαστελλω, to distinguish.) An exact and accurate distinction of one disease, or symptom, from another.

Antidi'nica. (From αντι, against, and δινος, circumgyration.) Medicines against a vertigo, or giddiness. *Blancard.*

Antidota'rium. (From αντιδοτος, an antidote.) A term used by former writers, for what we now call a dispensatory; a place where antidotes are prescribed and prepared. There are antidotaries extant of several authors, as those of *Nicholaus, Mesue, Myrepsus,* &c

ANTI'DOTUS. (From αντι, against, and διδωμι, to give.) A preservative against sickness. A remedy. *Galen.*

Antidysente'rica. (From αντι, against, and δυσεντερια, a flux.) Medicines against a dysentery, or flux.

Antifebri'lia. (From αντι, against, and *febris,* a fever.) A febrifuge, a remedy against fever.

Antihe'ctica. (From αντι, against, and εκτικος, a hectic fever.) Remedies against a hectic fever.

Antihe'cticum Pote'rii. *Antimonium diaphoreticum Joviale.* A medicine invented by Poterius, formerly extolled as effectual in hectic fevers, but now disregarded. It is an oxyd of tin and chalybeated regulus of antimony, in consequence of their deflagration with nitre.

ANTIHE'LIX. (From αντι, against, and ελιξ, the helix.) The inner circle of the auricle, so called from its opposition to the outer circuit called the helix.

Antihelmin'tica. See *Anthelmintics.*

Antihyster'ica. (From αντι, against, and ὑστερικα, hysterics.) Medicines which prevent or relieve hysterics.

Antile'psis. (From αντιλαμβανω, to take hold off.) The securing of bandages, or ligatures from slipping. *Hippocrates.*

Antilo'bium. (From αντι, opposite, and λοβος, the bottom of the ear.) The tragus, or that part of the ear which is opposite the lobe.

Antiloi'mica. (From αντι, against, and λοιμος, the plague.) Remedies or preventives against the plague.

Anti'lopus. The antelope. An African beast resembling a deer, whose hoofs and horns were formerly given in hysteric and epileptic cases.

Antily'ssus. (From αντι, against, and λυσσα, the bite of a mad dog.) A medicine or remedy against the bite of a mad dog.

Antimonial powder. See *Antimonialis pulvis.*

Antimonia'le. (From *antimonium.*) An antimonial, or composition in which antimony is a chief ingredient. A preparation of antimony.

Antimonia'lis pu'lvis. Antimonial powder. "Take of sulphuret of antimony, powdered, a pound; hartshorn shavings, two pounds." Mix and throw them into a broad iron pot heated to a white heat, and stir the mixture constantly until it acquires an ash colour. Having taken it out, reduce it to powder, and put it into a coated crucible, upon which another inverted crucible, having a small hole in its bottom, is to be luted. Then raise the fire by degrees to a white heat, and keep it so for two hours. Reduce the residuary mass to a very fine powder. The dose is from five to ten grains. It is in high esteem as a febrifuge, sudorific, and antispasmodic. The diseases in which it is mostly exhibited are, most species of asthenic and exanthematous fevers, acute rheumatism, gout, diseases arising from obstructed perspiration, dysuria, nervous affections, and spasms.

This preparation was introduced into the former London Pharmacopœia as a substitute for a medicine of extensive celebrity, Dr. James's powder; to which, however, the present form more nearly assimilates in its dose, and it is more manageable in its administration, by the reduction of the proportion of antimony to one half.

Antimo′nii O′xydum. *Oxyd of Antimony.* This preparation is now directed to be made by dissolving an ounce of tartarized antimony, and two drams of subcarbonate of ammonia, separately in distilled water, mixing the solutions and boiling, till the oxyd of antimony is precipitated, which is to be washed with water, and dried. This must not be confounded with the old calcined or diaphoretic antimony, being a much more active preparation. See *Antimony.*

In its effects, it will be found to agree pretty much with the antimonium tartarisatum; but it is very little employed.

Antimo′nii tartarizati liquor. Solution of tartarized antimony. *Vinum antimonii tartarizati* of the Pharm. Lond. 1787. "Take of tartarized antimony, one scruple; boiling distilled water, four fluid ounces; wine, six fluid ounces." Dissolve the tartarized antimony in the boiling distilled water, then add the wine. Half an ounce of the solution contains one grain of the salt. This preparation may be given in all cases where the tartar emetic is indicated.

Antimo′nii sulphure′tum præcipita′tum. *Sulphur antimonii præcipitatum.* Precipitated sulphuret of antimony. This preparation of antimony appears to have rendered that called Kermes mineral unnecessary. It is made thus:—

Take of sulphuret of antimony, in powder, two pounds; — of the solution of potash, four pints: — of distilled water, three pints.

Mix and boil the mixture over a slow fire for three hours stirring it well, and occasionally adding distilled water, so that the same measure may be preserved. Strain the solution forthwith through a double linen cloth; and while it is yet hot, drop in, gradually, as much sulphuric acid as may be required to precipitate the powder; then wash away the sulphate of potash, by hot water; dry the precipitated sulphuret of antimony, and reduce it to powder. In this process part of the water is decomposed, and its oxygen unites partly with the antimony; the oxyd of antimony as well as the potash combine with sulphur and hydrogen, forming hydrosulphuret of antimony and hydroguretted sulphuret of potash: if the solution be allowed to cool, the former of these partly precipitates, constituting the kermes mineral; but the addition of the sulphuric acid throws down the whole of it at once, mixed with some sulphur, furnished by the decomposition of the hydroguretted sulphuret of potash.

As an alterative and sudorific, it is in high estimation, and given in diseases of the skin and glands; and joined with calomel, it is one of the most powerful and penetrating alteratives we are in possession of.

ANTIMO′NIUM. See *Antimony.*

Antimo′nium calcina′tum. The volatile oxyd of antimony.

Antimo′nium diaphore′ticum. An old name for the volatile oxyd of antimony.

Antimo′nium tartariza′tum. *Tartarus emeticus. Tartarum emeticum. Tartarus antimonialis. Tartris antimonii cum potassâ. Tartarum stibiatum.* Tartar emetic is obtained by boiling the fusible oxyd of antimony with supertartrate of potash; the excess of tartaric acid dissolves the oxyd, and a triple salt is obtained by crystallization. The London Pharmacopœia directs thus:

Take of powdered sulphuret of antimony two ounces, nitrate of potash an ounce, supertartrate of potash two ounces, sulphuric acid two ounces by weight, distilled water a pint and a half; mix the acid with half a pint of the water in a suitable glass vessel, and heat them in a sand bath. When they are moderately heated, add gradually the nitre and sulphuret previously mixed; then boil, till the moisture is consumed. Wash the residuum with distilled water, till it is without flavour, and mix it, still moist with the supertartrate of potash, and throw them into a pint of distilled water: finally boil the liquor away sufficiently, and set it aside to crystallize. In the first part of this process, when nitre and sulphuret of antimony are boiled in dilute sulphuric acid, this gradually decomposes the nitre, and the nitric acid, as it is liberated oxidizes the antimony; the oxide of antimony, united probably to a small portion of sulphuric acid, appears in the form of a white powder: and it is by boiling this with the supertartrate of potash, which renders the oxide of antimony soluble, that the antimonium tartarizatum, or tartrate of antimony and potash, is formed. A solution of this salt in dilute wine is ordered in the pharmacopæia. See *Antimonii Tartarizati Liquor.*

Tartar emetic is the most useful of all the antimonial preparations. Its action is not dependent on the state of the stomach, and, being soluble in water, its dose is easily managed, while it also operates more speedily.

In doses of from one to three, four, or five grains, it generally acts powerfully as an emetic, and is employed whenever we wish to obtain the effects which result from full vomiting. As patients are differently affected by this medicine, the safest mode of exhibiting it is: ℞. *Antimonii tartarizati,* gr. iii. *Aquæ distillatæ,* ℥iv. Misce et cola.

Dosis ℥ss. omni horæ quadrante, donec supervenerit vomitus.

For children, emetic tartar is not so safe an emetic as ipecacuanha powder: when great debility of the system is present, even a small dose has been known to prove fatal to children. Sometimes it proves cathartic.

In smaller doses it excites nausea, and proves a powerful diaphoretic and expectorant. As an emetic it is chiefly given in the beginning of fevers and febrile diseases; when great debility is present, and in the advanced stages of typhoid fever its use is improper and even sometimes fatal. As a diaphoretic, it is given in small doses, of from an eighth to a quarter of a grain; and as an expectorant, in doses still smaller. Emetic tartar in small doses, combined with calomel, has been found a powerful yet safe alterative in obstinate eruptions of the skin. ℞. *Antimonii tartarizati*, gr. iv. *Hydrargyri submuriatis*, gr. xvi. *Confectionis Rosæ gallicæ*, q. s. Divide in pil. xxiv. Capiat i. mane nocteque ex thea sassafras.

In the form of powder, or dissolved in water, it is applied by a pencil to warts and obstinate ulcers: it is also given in the form of clyster, with a view to produce irritation in soporose diseases, apoplexy, ileus, and hernia incarcerata. The powder mixed with any fluid, and rubbed on the scrobiculus cordis, excites vomiting. Another property which tartar emetic has, when rubbed on the skin, is that of producing a crop of pustules very like to the small-pox, and with this view it is used against rheumatic pains, white, and other obstinate swellings. The best antidote against the bad effects of too large a quantity of this and other antimonial preparations, is a decoction of the bark of cinchona: in defect of which, tea and other astringents may be used.

Antimo'nium vitrifactum. Glass of antimony. An oxid of antimony, with a little sulphuret.

ANTIMONY. (*Antimonium*, i. n. Αντιμονιον. The origin of this word is very obscure. The most received etymology is, from αντι, against, and μονος, a monk; because Valentine, by an injudicious administration of it, poisoned his brother monks.) *Antimonium Stibium.* A metal found *native*, but very rarely; it has, in that state, a metallic lustre, and is found in masses of different shapes; its colour is white, between those of tin and silver. It generally contains a small portion of arsenic. It is likewise met with in the state of an oxyd, *antimonial ochre*. The most abundant ore of it is that in which it is combined with sulphur, *the grey ore of antimony*, or *sulphuret of antimony*. The colour of this ore is blueish, or steel-grey, of a metallic lustre, and often extremely beautifully variegated. Its texture is either compact, foliated, or striated. The striated is found both crystallized, massive, and disseminated: there are many varieties of this ore.

Properties of Antimony. — Antimony is a metal of a greyish white, having a slight blueish shade, and very brilliant. Its texture is lamellated, and exhibits plates crossing each other in every direction. Its surface is covered with herbarizations and foliage. Its specific gravity is, 6.702. It is sufficiently hard to scratch all the soft metals. It is very brittle, easily broken, and pulverizable. It fuses at 810° Fahr. It can be volatilized, and burns by a strong heat. When perfectly fused, and suffered to cool gradually, it crystallizes in octahedra. It unites with sulphur and phosporus. It decomposes water strongly at a red heat. It is soluble in alkaline sulphurets. Sulphuric acid, boiled upon antimony, is feebly decomposed. Nitric acid dissolves it in the cold. Muriatic acid scarcely acts upon it. The oxigenated muriatic acid gas inflames it, and the liquid acid dissolves it with facility. Arsenic acid dissolves it by heat with difficulty. It unites, by fusion, with gold, and renders it pale and brittle. Platina, silver, lead, bismuth, nickel, copper, arsenic, iron, cobalt, tin, and zinc, unite with antimony by fusion, and form with it compounds, more or less brittle. Mercury does not alloy with it easily unless very pure. We are little acquainted with the action of alkalies upon it. Nitrate of potash is decomposed by it. It fulminates by percussion with oxigenated muriate of potash. Antimony forms at least two definite compounds with oxygen One may be obtained by the action of muriatic acid, adding water to the solution, which precipitates the oxide in union with a little acid, which may be separated by boiling for some time in a solution of subcarbonate of potash; it is of a dull brownish white colour, fusible at a moderate red heat, but hardly volatilized without access of air, which carries the oxidizement farther. The other oxide is formed by the combustion of the metal, subliming as a fine white powder, which requires a much higher temperature for its fusion than the preceding. It is very important to distinguish these two compounds; the former, or fusible oxide, combines most readily with acids, and possesses much greater activity as a medicine, than the volatile oxide; indeed it appears to be the basis of all those antimonial preparations, on which any reliance can be placed.

Methods of obtaining antimony. — 1. To obtain antimony, heat 32 parts of filings of iron to redness, and project on them, by degrees, 100 parts of antimony; when the whole is in fusion, throw on it, by degrees, 20 parts of nitrate of potash, and after a few minutes quiet fusion, pour it into an iron melting cone, previously heated and greased.

2. It may also be obtained by melting eight parts of the ore mixed with six of nitrate of potash, and three of supertartrate of potash, gradually projected into a red-hot crucible, and fused.

To obtain perfectly pure antimony, Margraaf melted some pounds of the sulphuret in a luted crucible, and thus scorified any metals it might contain. Of the antimony thus purified, which lay at the bottom, he took sixteen ounces, which he oxidized cautiously, first with a slow, and afterwards with a strong heat, until it ceased to smell of sulphur, and acquired a greyish-white colour. Of this grey powder he took four ounces, mixed them with six drachms of supertartrate of potash, and three of charcoal, and kept them in fusion in a well covered and luted crucible, for one hour, and thus obtained a metallic button that weighed one ounce, seven drachms, and twenty grains.

The metal, thus obtained, he mixed with half its weight of desiccated subcarbonate of soda, and covered the mixture with the same quantity of the subcarbonate. He then melted it in a well covered and luted crucible, in a very strong heat, for half an hour, and thus obtained a button which weighed one ounce, six drachms, and seven grains, much whiter and more beautiful than the former. This he again treated with one and a half ounce of subcarbonate of soda, and obtained a button, weighing one ounce, five drachms, and six grains. This button was still purer than the foregoing. Repeating these fusions with equal weights of subcarbonate of soda three times more, and an hour and a half each time, he at last obtained a button so pure as to amalgamate with mercury with ease, very hard, and in some degree malleable; the scoriæ formed in the last fusion were transparent, which indicated that they contained no sulphur, and hence it is the obstinate adherence of the sulphur that renders the purification of this metal so difficult.

The preparations of antimony formerly in use were very many: those now directed to be kept are: —

1. Sulphuretum antimonii.
2. Oxydum antimonii.
3. Sulphuretum antimonii præcipitatum.
4. Antimonium tartarizatum.
5. Pulvis antimonialis.
6. Liquor antimonii tartarizati.

Anti′moris. (From αντι, against, and μορος, death, or disease.) A medicine to prolong life.

Antinephri′tica. (From αντι, against, and νεφριτις, a disease of the kidneys.) Remedies against disorders of the kidneys. *Blancard.*

Antiodonta′lgicus. An insect described by Germi in a small work published at Florence 1794, so called from its property of allaying the tooth-ache. It is a kind of curculio found on a species of thistle, carduus spinosissimus. If twelve or fifteen of these insects in the state of larvæ, or when come to perfection, be bruised and rubbed slowly between the fore-finger and thumb until they have lost their moisture; and if the painful tooth where it is hollow, be touched with that finger, the pain ceases sometimes instantaneously. A piece of shamoy leather will answer the same purpose with the finger. If the gums are inflamed, the remedy is of no avail. Other insects possess the property of curing the tooth-ache; such as the scarabeus ferrugineus of Fabricius; the coccinella septempunctata, or lady-bird; the chrysomela populi, and the chrysomela sanguinolenta. This property belongs to several kinds of the coleoptera.

Antiparaly′tica. (From αντι, against, and παραλυσις, the palsy.) Medicines against the palsy.

Antipathei′a. (From αντι, against, and παθος, an affection.) Antipathy. An aversion to particular objects.

Antiperista′ltic. (From αντι, against, and περιστελλω, to contract.) Whatsoever obstructs the peristaltic motion of the intestines.

Antiperi′stasis. (From αντι, against, and περιστημι, to press.) A compression on all sides. *Theophrastus de igne.*

Antipha′rmaca. (From αντι, against, and φαρμακον, a poison.) The same as alexipharmaca. Remedies or preservatives against poison. *Dioscorides.*

ANTIPHLOGI′STICA. (From αντι, against, and φλεγω, to burn.) Antiphlogistics. A term applied to those medicines, plans of diet, and other circumstances, which tend to oppose inflammation, or which, in other words, weaken the system by diminishing the activity of the vital power.

Antiphthi′sica. (From αντι, against, and φθισις, consumption.) Remedies against a consumption.

Anti′phthora. (From αντι, against, and φθορα, corruption.) A species of wolfsbane which resists corruption.

Antiphy′sica. (From αντι, against, and φυσαω, to blow.) Carminatives or remedies against wind.

Antipleuri′tica. (From αντι, against, and πλευριτις, pleurisy.) Remedies against a pleurisy.

Antipoda′grica. (From αντι, against, and ποδαγρα, the gout.) Medicines which relieve or remove the gout.

Antipra′xia. (From αντι, against, and πρασσω, to work.) A contrariety of functions and temperaments in divers parts. Contrariety of symptoms.

Antipyre′tica. (From αντι, against, and πυρετος, fever.) *Antifebrile.* Remedies against a fever.

Antiquartana′ria. (From αντι, against, and *quartana*, a quartan fever.) Remedies against quartan agues.

Antiqua'rticum. The same as Antiquartanaria.

ANTIRRHI'NUM. (Αντιῤῥινον: from αντι, against, and ῥις, the nose; so called because it represents the nose of a calf.) Snap-dragon, or calf's-snout. The name of a genus of plants in the Linnæan system. Class, *Didynamia*. Order, *Angiospermia*.

Antirrhi'num lina'ria. The systematic name for the *linaria* of the pharmacopœias. *Osyris. Urinaria.* Common toad-flax. *Antirrhinum foliis lanceolatis linearibus confertis, caule erecto, spicis terminalibus sessilibus, floribus imbricatis*, of Linnæus. A perennial indigenous plant, common in barren pastures, hedges, and the sides of roads, flowering from July to September. The leaves have a bitterish and somewhat saline taste, and when rubbed between the fingers, have a faint smell, resembling that of elder. They are said to be diuretic and cathartic, and in both characters to act powerfully, especially in the first; hence the name *urinalis*. They have been recommended in dropsies and other disorders requiring powerful evacuations. The linaria has also been used as a resolvent in jaundice, and such diseases as were supposed to arise from visceral obstructions. But the plant has been chiefly valued for its effects when externally applied, especially in hæmorrhoidal affections, for which both the leaves and flowers have been employed in various forms of ointment, fomentation, and poultice. Dr. Wolph first invented an ointment of this plant for the piles. The Landgrave of Hesse, to whom he was physician, constantly interrogated him, to discover its composition; but Wolph obstinately refused, till the prince promised to give him a fat ox annually for the discovery: hence, to the following verse, which was made to distinguish the linaria from the escula, viz.

"*Esula lactescit, sine lacte linaria crescit,*"

The hereditary Marshal of Hesse, added,

"*Esula nil nobis, sed dat linaria taurum.*"

Antirrhi'num elatine. The systematic name of the plant we call fluellen, or female speedwell. *Elatine* of the shops. The leaves of this plant have a roughish bitter taste, but no smell. It was formerly much used against scurvy and old ulcerations, but now wholly forgotten.

Antisco'lica. (From αντι, against, and σκωληξ, a worm.) Remedies against worms. Anthelmintics.

ANTISCORBU'TICS. (*Antiscorbutica*, sc. *medicamenta*; from αντι, against, and *scorbutus*, the scurvy.) Medicines which cure the scurvy.

ANTISEPTICS. (*Antiseptica*, sc. *medicamenta*; from αντι, against, and σηπω, to putrefy.) Those medicines which possess a power of preventing animal substances from passing into a state of putrefaction, and of obviating putrefaction when already begun. This class of medicines comprehends four orders.

1. *Tonic antiseptics*, as cinchona, *cuspariæ cortex*, chamæmelum, &c. which are suited for every condition of body, and are, in general, preferable to other antiseptics, for those with relaxed habits.

2. *Refrigerating antiseptics*, as acids, which are principally adapted for the young, vigorous, and plethoric.

3. *Stimulating antiseptics*, as wine and alkohol, best adapted for the old and debilitated.

4. *Antispasmodic antiseptics*, as camphora and asafœtida, which are to be selected for irritable and hysterical habits.

Anti'spasis. (From αντι, against, and σπαω, to draw.) A revulsion. The turning the course of the humours, whilst they are actually in motion. *Galen*.

ANTISPASMODICS. (*Antispasmodica*, sc. *medicamenta*; from αντι, against, and σπασμος, a spasm.) Medicines which possess the power of allaying, or removing, inordinate motions in the system, particularly those involuntary contractions which take place in muscles, naturally subject to the command of the will. Spasm may arise from various causes. One of the most frequent is a strong irritation, continually applied; such as dentition, or worms. In these cases, narcotics prove useful, by diminishing irritability and sensibility. Sometimes spasm arises from mere debility; and the obvious means of removing this is by the use of tonics. Both narcotics and tonics, therefore, are occasionally useful as antispasmodics, such as opium, camphor, and ether, in the one class, and zinc, mercury, and Peruvian bark, in the other. But there are farther, several other substances, which cannot be with propriety referred to either of these classes; and to these, the title of antispasmodics is more exclusively appropriated. The principal antispasmodics, properly so called, are moschus, castoreum, oleum animale empyreumaticum, petroleum, ammonia, asafœtida, sagapenum, galbanum, valeriana, crocus, melaleuca leucadendron.

The narcotics, used as antispasmodics, are ether, opium, camphor.

Tonics, used as antispasmodics, are cuprum, zincum, hydrargyrum, cinchona.

Anti'thenar. (From αντι, against, and θεναρ, the palm of the hand.) A muscle of the foot. See *Adductor pollicis pedis*.

Antitra'gicus. *Antitragus*. (*Antitragicus*, sc. *musculus*.) One of the proper muscles of the ear, whose use is to turn up the tip of the antitragus a little outwards, and to depress the extremity of the antihelix towards it.

Antitra'gus. (*Antitragus*, i, m. from

αντι, and τραγος, the tragus.) An eminence of the outer ear, opposite to the tragus.

Antivene'rea. (From αντι, against, and *venereus*, venereal.) Medicines against the lues venerea.

Anto'nii Sa'ncti i'gnis. (So called because St. Anthony was supposed to cure it miraculously. In the Roman Missal, St. Anthony is implored as being the preserver from all sorts of fire.) St. Anthony's fire. See *Erysipelas*.

Antophy'llon. (From αντι, against, and φυλλον, a leaf; so called because its leaves are opposite.) The male caryophyllus.

A'NTRUM OF HIGHMORE. (From the name of an anatomist, who gave the first accurate description of it.) *Antrum Highmorianum*. *Antrum genæ*. *Sinus maxillaris pituitarius*. *Antrum maxillæ superioris*. Maxillary sinus. A large cavity in the middle of each superior maxillary bone, between the eye and the roof of the mouth, lined by the mucous membrane of the nose.

One or both antra are liable to several morbid affections. Sometimes their membranous lining inflames, and secretes pus. At other times, in consequence of inflammation, or other causes, various excrescences and fungi are produced in them. Their bony parietes are occasionally affected with exostosis, or caries. Extraneous bodies may be lodged in them, and it is even asserted that insects may be generated in them, and cause, for many years, afflicting pains. Abscesses in the antrum are by far the most common. Violent blows on the cheek, inflammatory affections of the adjacent parts, and especially of the pituitary membrane lining the nostrils, exposure to cold and damp, and, above all things, bad teeth, may induce inflammation and suppuration in the antrum. The first symptom is a pain, at first imagined to be a tooth-ache, particularly if there should be a carious tooth at this part of the jaw. This pain, however, extends more into the nose than that usually does which arises from a decayed tooth; it also affects, more or less, the eye, the orbit, and the situation of the frontal sinuses. But even such symptoms are insufficient to characterise the disease, the nature of which is not unequivocally evinced, till a much later period. The complaint is, in general, of much longer duration than one entirely dependent on a caries of the tooth, and its violence increases more and more, until at last a hard tumour becomes perceptible below the cheek-bone. The swelling by degrees extends over the whole cheek; but it afterwards rises to a point, and forms a very circumscribed hardness, which may be felt above the back-grinders. This symptom is accompanied by redness, and sometimes by inflammation and suppuration of the external parts. It is not uncommon also, for the outward abscess to communicate with that within the antrum. The circumscribed elevation of the tumour, however, does not occur in all cases. There are instances in which the matter makes its way towards the palate, causing the bones of the part to swell, and at length rendering them carious, unless timely assistance be given. There are other cases, in which the matter escapes between the fangs and sockets of the teeth. Lastly, there are other examples, in which matter, formed in the antrum, makes its exit at the nostril of the same side, when the patient is lying with his head on the opposite one, in a low position. If this mode of evacuation should be frequently repeated, it prevents the tumour both from pointing externally, and bursting, as it would do if the purulent matter could find no other vent. This evacuation of the pus from the nostril is not very common. The method of cure consists in extracting one of the dentes molares from the affected side; and then perforating through the socket into the bony cavity. A mild injection may afterwards be employed to cleanse the sinus occasionally. [Cyclopædia.]

A'ntrum buccino'sum. The cochlea of the ear.

A'ntrum pylo'ri. The great concavity of the stomach approaching the pylorus.

A'ntrum maxilla're. See *Antrum of Highmore*.

Ants, acid of. See *Formic acid*.

Anty'lion. (From *Antyllus*, its inventor.) An astringent application, recommended by Paulus Ægineta.

A'NUS. (*Anus*, *i*, masc. *quasi onus*; as carrying the burden of the bowels.)

1. The fundament; the lower extremity of the great intestine, named the rectum, is so called; and its office is to form an outlet for the fæces. The anus is furnished with muscles which are peculiar to it, viz. the *sphincter*, which forms a broad circular band of fibres, and keeps it habitually closed, and the *levatores ani*, which serve to dilate and draw it up to its natural situation, after the expulsion of the fæces. It is also surrounded, as well as the whole of the neighbouring intestine, with muscular fibres, and a very loose sort of cellular substance. The anus is subject to various diseases, especially piles, ulceration, abscesses, excrescences, prolapsus; and imperforation in new-born infants.

2. The term *anus* is also applied to a small opening of the third ventricle of the brain, which leads into the fourth.

Anus, artificial. An accidental opening in the parietes of the abdomen, to which opening some part of the intestinal canal leads, and through which the fæces are either wholly or in part discharged. When a strangulated hernia occurs, in which the intestine is simply pinched, and this event is unknown; when it has not been relieved b the usual means; or when the necessary operation has not been practised in time;

the protruded part becomes gangrenous, and the fæces escape. But if the patient should be at last operated upon, his fæces are discharged through the wound, and the intestines are more easily emptied. In both cases, the excrement continues to be discharged from the artificial opening. In this way an artificial anus is formed, through which the excrement is evacuated during life.

Any′drion. (From α, priv. and υδωρ, water; so called, because they who eat of it become thirsty.) A species of nightshade, according to Blancard.

Anypeu′thynus. (From α, neg. and υπευθυνος, blamable.) Hippocrates, in his Precepts, uses this word to signify an accidental event, which cannot be charged on the physician, and for which he is not accountable.

AO′RTA. (From αηρ, air, and τηρεω, to keep; so called because the antients supposed that only air was contained in it.) The great artery of the body, which arises from the left ventricle of the heart, forms a curvature in the chest, and descends into the abdomen. See *Artery*.

Apalachi′ne ga′llis. (From απαλακω, to repel; because it is supposed to repel infection.) See *Ilex Cassine.*

Apari′ne. (From ρινη, a file; because its bark is rough, and rasps like a file.) Goose-grass. See *Galium Aparine.*

Aparthro′sis. (From απο and αρθρον, a joint.) Articulation.

Ape′lla. (From α, priv. and *pellis*, skin.) Shortness of the prepuce. Galen gives this name to all whose prepuce, either through disease, section, or otherwise, will not cover the glans.

Ape′psia. (*Apepsia, æ*, f. απεψια: from α, priv. and πεπτω, to digest.) Indigestion. See *Dyspepsia.*

Ape′riens palpebra′rum re′ctus. See *Levator palpebræ superioris.*

APERIENTS. (*Aperientia*, sc. *medicamenta;* from *aperio*, to open.) Laxatives. Medicines which gently open the bowels.

Aperi′status. (From α, neg. and περιστημι, to surround.) *Aperistaton.* An epithet used by Galen, of an ulcer which is not dangerous, nor surrounded by inflammation.

Aperi′staton. See *Aperistatus.*

Ape′rtor o′culi. See *Levator palpebræ superioris.*

Apeuthy′smenus. (From απο and ευθυς, straight.) A name formerly given to the intestinum rectum, or straight gut.

A′PEX. The extremity of a part; as the apex of the tongue, apex of the nose, &c.

Aphani′smus. (From αφανιζω, to remove from the sight.) The removal, or gradual decay, of a disorder.

Aphæ′resis. (From αφαιρεω, to remove.) This term was formerly much used in the schools of surgery, to signify that part of the art which consists in taking off any diseased or preternatural part of the body.

Aphepse′ma. (From απο, and εψω, to boil.) A decoction.

A′phesis. (From αφιημι, to remit.) The remission or termination of a disorder.

Aphiste′sis. (From αφιστημι, to draw from.) An abscess.

A′phodos. (From απο, and οδος, departure.) Excrement. The dejection of the body.

APHO′NIA. (Αφωνια: from α, priv. and φωνη, the voice.) A suppression of the voice, without either syncope or coma. A genus of disease in the class *locales*, and order *dyscinesiæ* of Cullen.

When it takes place from a tumour of the fauces, or about the glottis, it is termed *aphonia gutturalis;*

When from a disease of the trachea, *aphonia trachealis;*

And when from a paralysis, or want of nervous energy, *aphonia atonica.*

A′PHORISM. (*Aphorismus;* from αφοριζω, to distinguish.) A maxim, or principle, comprehended in a short sentence.

Aphrodi′sia. (From Αφροδιτη, Venus.) An immoderate desire of venery.

APHRODISIACS. (*Aphrodisiaca*, sc. *medicamenta*, αφροδισιακα; from αφροδισια, venery.) Medicines which excite a desire for venery.

Aphrodisia′sticon. (From αφρος, froth.) A troch so called by Galen, because it was given in dysenteries, where the stools were frothy.

Aphrodi′sius mo′rbus. (From Αφροδιτη, Venus.) The venereal disease.

A′phtha. See *Aphthæ.*

A′PHTHÆ. (Αφθαι: from απτω, to inflame.) The thrush. Frog, or sore mouth. *Aphtha lactucimen* of Sauvages. *Ulcera serpentia oris*, or spreading ulcers in the mouth, of Celsus. *Pustula oris. Alcola. Vesiculæ gingivarum. Acacos. Aphtha infantum.* It is ranked by Cullen in the class *Pyrexiæ*, order *Exanthemata.* A disease to which children are very subject. It appears in small white ulcers upon the tongue, gums, and around the mouth and palate, resembling small particles of curdled milk. When the disease is mild, it is confined to these parts; but when it is violent and of long standing, it is apt to extend through the whole course of the alimentary canal, from the mouth down to the anus; and so to excite severe purgings, flatulencies, and other disagreeable symptoms. The disease, when recent and confined to the mouth, may in general be easily removed; but when of long standing, and extending down to the stomach and intestines, it very frequently proves fatal.

The thrush sometimes occurs as a chronic disease, both in warm climates and in those Northern countries where the cold is combined with a considerable degree of moisture, or where the soil is of a very marshy nature. It may, in some cases, be considered as an idiopatic affection; but it is more usually symptomatic. It shews itself, at first, by an uneasy sensation, or burning heat in the stomach, which comes on by slow degrees, and increases gradually in violence. After some time, small pimples, of about the size of a pin's head, shew themselves on the tip and edges of the tongue; and these, at length, spread over the whole inside of the mouth, and occasion such a tenderness and rawness, that the patient cannot take any food of a solid nature; neither can he receive any vinous or spirituous liquor into his mouth, without great pungency and pain being excited; little febrile heat attends, but there is a dry skin, pale countenance, small pulse, and cold extremities. These symptoms will probably continue for some weeks, the general health being sometimes better and sometimes worse, and then the patient will be attacked with acid eructations, or severe purging, which greatly exhausts its strength, and produces considerable emaciation of the whole body. After a little time, these symptoms cease, and he again enjoys better health; but, sooner or later, the acrid matter shews itself once more in the mouth, with greater virulence than before, and makes frequent translations to the stomach and intestines, and so from these to the mouth again, until, at last, the patient is reduced to a perfect skeleton. Elderly people, and persons with a shattered constitution, are most liable to its attacks. The treatment of the thrush in children is generally to be begun by the exhibition of a gentle emetic: then clear the bowels, if confined, by rhubarb and magnesia, castor oil, or other mild aperient; or sometimes in gross torpid habits by a dose of calomel. In general the prevalence of acid in the primæ viæ appears to lead to the complaint; whence antacid remedies prove beneficial in its progress: when the patient is costive giving the preference to magnesia; when relaxed, to chalk, which may be sometimes joined with aromatics, the mild vegetable astringents, or even a little opium, if the diarrhœa be urgent. Where the child is very weak, and the aphthæ of a dark colour, the decoction of bark or other tonic must be had recourse to. The separation of the sloughs and healing of the ulcers may be promoted by washing the mouth occasionally with the honey of borax, diluted with two or three parts of rose water; or where they are of a dark colour, by the decoction of bark acidulated with sulphuric acid. The diet should be light and nutritious, especially where there is much debility. As the complaint is subsiding, particular attention is required to obviate the bowels becoming confined. In the chronic aphthæ affecting grown persons, pretty much the same plan of treatment is to be pursued: besides which the compound powder of ipecacuanha and other diaphoretics, assisted by the occasional use of the warm bath, wearing flannel next the skin, particularly in a damp cold climate, &c. appear to be beneficial.

A'pis melli'fica. The systematic name of the honey-bee. See *Bee*.

A'PIUM. (*Apium, i, n.* From ηπιος, *Doricè* απιος, mild; or from *apes*, bees; because they are fond of it.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Digynia*.

2. The pharmacopœial name of the herb small-age.

A'pium grave'olens. The systematic name for the *apium* of the pharmacopœias. *Apium, foliolis caulinis, cuneiformibus, umbellis, sessilibus*, of Linnæus. The root, seeds, and fresh plant, are aperient and carminative.

A'pium petroseli'num. The systematic name for the *petroselinum* of the pharmacopœias. *Petroselinum vulgare. Apium hortense.* Common parsley. *Apium foliis caulinis linearibus, involucellis minutis* of Linnæus. Both the roots and seeds of this plant were formerly directed by the London College for medicinal use, and the root is still retained in the Edinburgh pharmacopœia: the former have a sweetish taste, accompanied with a slight warmth or flavour, somewhat resembling that of carrot; the latter are in taste warmer and more aromatic than any other part of the plant, and manifest considerable bitterness. The roots are said to be aperient and diuretic, and have been employed in nephritic pains and obstructions of urine. The seeds possess aromatic and carminative powers, but are seldom prescribed.

Apneu'stia. (From α, and πνεω, to breathe.) A defect or difficulty of respiration, such as happens in a cold, &c. *Foësius.*

Apnœ'a. The same. *Galen.*

Apocapni'smus. (From απο, and καπνος, smoke.) A fumigation.

Apocatha'rsis. (From απο, and καθαιρω, to purge.) An evacuation of humours; a discharge downward; but sometimes applied, with little discrimination, to vomiting.

Apocaulize'sis. (From αποκαυλιζω, to break transversely.) A transverse fracture. *Hippocrates.*

APOCENO'SIS. (From απο, and κενοω, to evacuate.) A superabundant flux of blood, or other fluid, without pyrexia. The name of an order in the class *locales* of Cullen.

Apo'cope. (From απο, and κοπτω, to cut from.) Abscission, or the removal of a part by cutting it off.

Apo'crisis. (From απο, and κρινω, to secrete from.) A secretion of suberabundant humours. *Hippocrates.*

Apocru'stinum. *Apocrusticon.* (From

αποκρουω, to repel.) An astringent or repellent medicine. *Galen.*

Apocru′sticon. See *Apocrustinum.*

Apocye′sis. (From απο, and κυω, to bring forth.) Parturition, or the bringing forth of a child. *Galen.*

Apodacry′tica. (From απο, and δακρυ, a tear.) Medicines which, by exciting tears, remove superfluous humours from the eyes, as onions, &c. *Pliny.*

Apogeu′sia. See *Ageustia.*

Apogeu′sis. See *Ageustia.*

Apoginome′sis. (From απογινομαι, to be absent.) The remission or absence of a disease. *Hippocrates.*

Apoglauco′sis. (From απο, and γλαυκος, sky-coloured; so called because of its blueish appearance.) Glaucoma. A cataract of the eye. *Dioscorides.*

Apo′gonum. (From απο, and γινομαι, to beget.) A living fœtus in the womb. *Hippocrates.*

Apole′psis. (From απο, and λαμβανω, to take from.) An interception, suppression, or retention of urine, or any other natural evacuation. *Hippocrates.*

Apolino′sis. (From απο, and λινον, flax.) The method of curing a fistula, according to Ægineta, by the application of raw flax.

Apo′lysis. (From απο, and λυω, to release.) The solution or termination of a disease. The removal of a bandage. *Erotianus.*

Apoma′gma. (From απο, and ματτω, to cleanse from.) Any thing used to cleanse and wipe away filth from sores, as sponge, &c. *Hippocrates.*

Apomathe′ma. (From απο, neg. and μανθανω, to learn.) Hippocrates expresses, by this term, a forgetfulness of all that has been learnt.

Apo′meli. (From απο, from, and μελι, honey.) An oxymel, or decoction, made with honey.

APONEURO′SIS. (From απο, and νευρον, a nerve; from an erroneous supposition of the antients, that it was formed by the expansion of a nerve.) A tendinous expansion. See *Muscle.*

Apo′nia. (From α, priv. and ϖονος, pain.) Freedom from pain.

Aponitro′sis. (From απο, and νιτρον, nitre.) The sprinkling an ulcer over with nitre.

Apopalle′sis. (From αποπαλλω, to throw off hastily.) An abortion, or premature expulsion of a fœtus. *Hippocrates.*

Apopeda′sis. (From απο, and ϖηδαω, to jump from.) A luxation.

Apophlegma′sia. (From απο, and φλεγμα, phlegm.) A discharge of phlegm, or mucus.

Apophlegma′tica. (From απο, and φλεγμα, phlegm.) *Apophlegmatizantia. Apophlegmatizonta.* Medicines which excite the secretion of mucus from the mouth and nose. Masticatories. Errhines.

Apophra′xis. (From απο, and φρασσω, to interrupt.) A suppression of the menstrual discharge.

Apophtha′rma. (From απο, and φθειρω, to corrupt.) A medicine to procure abortion.

Apo′phthora. (From αποφθειρω, to be abortive.) An abortion.

Apophy′ades. The ramifications of the veins and arteries. *Hippocrates.*

Apo′phyas. (From αποφυω, to proceed from.) Any thing which grows or adheres to another, as a wart to the finger.

APO′PHYSIS. (From αποφυω, to proceed from.) *Appendix. Probole. Ecphysis. Processus. Productio. Projectura. Protuberantia.* A process, projection, or protuberance, of a bone beyond a plain surface; as the nasal apophysis of the frontal bone, &c.

Apophthe′gma. (From αποφθεγγομαι, to speak eloquently.) A short maxim, or axiom; a rule.

Apople′cta. A name formerly applied to the internal jugular vein; so called because in apoplexies, it appears full and turgid. *Bartholin.*

Apople′ctica. (From αποπληξια, an apoplexy.) Medicines against an apoplexy.

APOPLE′XIA. (From απο, and ϖλησσω, to strike or knock down; because persons, when seized with this disease, fall down suddenly.) Apoplexy. A sudden abolition, in some degree of the powers of sense and motion, the patient lying in a sleep-like state; the action of the heart remaining, as well as the respiration, often with a stertorous noise. Cullen arranges it in the class *neuroses,* and order *comata.*

1. When it takes place from a congestion of blood, it is termed *apoplexia sanguinea.*

2. When there is an abundance of serum, as in persons of a cold temperament, *apoplexia serosa.*

3. If it arise from water in the ventricles of the brain, it is called *apoplexia hydrocephalica.* See *Hydrocephalus.*

4. If from a wound, *apoplexia traumatica.*

5. If from poisons, *apoplexia venenata.*

6. If from the action of suffocating exhalations, *apoplexia suffocata.*

7. If from passions of the mind, *apoplexia mentalis.*

8. And when it is joined with catalepsy, *apoplexia cataleptica.*

Apoplexy makes its attack chiefly at an advanced period of life; and most usually on those who are of a corpulent habit, with a short neck, and large head; and who lead an inactive life, make use of a full diet, or drink to excess. The immediate cause of apoplexy, is a compression of the brain, produced either by an accumulation of blood in the vessels of the head, and distending them to such a degree, as to compress the medullary portion of the brain; or by an effusion of blood from the red vessels, or of serum from the exhalants; which fluids are accumulated in such a quantity as to occasion compression. These states, of over-distension and of effusion, may be brought on by whatever increases the afflux and impetus of the blood in the arteries of the head; such as violent fits of passion, great exertions of muscular strength, severe exercise, excess in venery, stooping down for any length of time, wearing any thing too tight about the neck, overloading the stomach, long exposure to excessive cold, or a vertical sun, the sudden suppression of any long-accustomed evacuation, the application of the fumes of certain narcotic and metallic substances, such as opium, alkohol, charcoal, mercury, &c. and by blows, wounds, and other external injuries: in short, apoplexy may be produced by whatever determines too great a flow of blood to the brain, or prevents its free return from that organ.

The young, and those of a full plethoric habit, are most liable to attacks of the sanguineous apoplexy; and those of a phlegmatic constitution, or who are much advanced in life, to the serous. Apoplexy is sometimes preceded by head-ache, giddiness, dimness of sight, loss of memory, faltering of the tongue in speaking, numbness in the extremities, drowsiness, stupor, and night-mare, all denoting an affection of the brain; but it more usually happens that, without much previous indisposition, the person falls down suddenly, the countenance becomes florid, the face appears swelled and puffed up, the vessels of the head, particularly of the neck and temples, seem turgid and distended with blood; the eyes are prominent and fixed, the breathing is difficult and performed with a snorting noise, and the pulse is strong and full. Although the whole body is affected with the loss of sense and motion, it nevertheless takes place often more upon one side than the other, which is called hemiplegia, and in this case, the side least affected with palsy is somewhat convulsed.

In forming an opinion as to the event, we must be guided by the violence of the symptoms. If the fit is of long duration, the respiration laborious and stertorous, and the person much advanced in years, the disease, in all probability, will terminate fatally. In some cases, it goes off entirely; but it more frequently leaves a state of mental imbecility behind it, or terminates in a hemiplegia, or in death. Even when an attack is recovered from, it most frequently returns again, after a short period of time, and in the end proves fatal. In dissections of apoplexy, blood is often found effused on the surface and in the cavities of the brain; and in other instances, a turgidity and distention of the blood-vessels are to be observed. In some cases, tumours have been found attached to different parts of the substance of the brain, and in others, no traces of any real affection of it could be observed.

On an attack of sanguineous apoplexy, all compression should be removed from the neck, the patient laid with his head a good deal raised, and a free admission of cool air allowed. Then blood should be taken freely from the arm or the temporal artery, or the jugular vein; which it may be sometimes necessary to repeat, if the symptoms continue, and the patient is still plethoric; or if blood can less be spared, cupping or leeches may lessen the congestion in the brain. The next object should be thoroughly to evacuate the bowels by some active purgative, as calomel joined with jalap, or with extract of colocynth, or followed by infusion of senna and some neutral salt, with a little tartarized antimony or tincture of jalap repeated every two hours till it operates; or a draught of tincture of senna and wine of aloes, where the bowels are very torpid, may answer the purpose. Stimulant glysters will also be proper, particularly if the patient cannot swallow, as common salt and syrup of buckthorn with a proper quantity of gruel, infusion of senna or infusion of colocynth; or a turpentine glyster in elderly torpid habits. Cold should then be applied assiduously to the scalp, the hair being previously shaved, and a blister to the back of the neck; and diaphoretic medicines may be exhibited, avoiding however those which contain opium. Sinapisms to the feet may also be useful, particularly if these are cold. If under these means, the sensibility does not gradually return, some of the gentle diffusible stimulants will be proper, as ammonia, mustard, æther, camphor, &c.: and at this period, a blister to the scalp may come in aid. By some practitioners emetics are recommended, but their use is hazardous, especially if sufficient evacuations be not premised: and the same may be observed of sternutatories. In the serous form of the disease, general bleeding is inadmissible, and even the local abstraction of blood should be very sparingly made; the bowels should be kept open, especially by aloetic or mercurial formulæ, but not procuring profuse discharges; and the other secretions maintained, especially by the use of the diffusible stimulants already mentioned; blisters to the head, and errhines may be here also useful. When apoplectic symptoms have been occasioned by opium, or other narcotic, the timely discharge of this by an active emetic will be the most important measure; but in a plethoric habit, bleeding should be premised: subsequently various stimulants may be employed, as ammonia, vinegar, &c. endeavouring to procure a determination to the surface, and rousing the patient from his torpid state. The prevention of the sanguineous form of the disease will be best attempted by abstemiousness, regular moderate exercise, and keeping up the evacuations; an issue or seton may also be useful; but under urgent circumstances, bleeding, especially topical, must be resorted to. In leucophlegmatic habits, a more nutritious diet will be proper.

Apopni′xis. (From αποπνιγω, to suffocate.) A suffocation. *Moschion.*

Apopsophe′sis. (From απο, and ψοφεω, to emit wind.) The emission of wind by the anus or uterus, according to Hippocrates.

Apopsy′chia. (From απο, from, and ψυχη, the mind.) The highest degree of deliquium, or fainting, according to Galen.

Apo′ptosis. (From αποπιπτω, to fall down.) A prolapsus, or falling down of any part through relaxation. *Erotian.*

Apore′xis. (From απο, and ορεγω, to stretch out.) A play with balls, in the gymnastic exercises.

Apo′ria. (From α, priv. and ϖορος, a duct.) Restlessness, uneasiness, occasioned by the interruption of perspiration, or any stoppage of the natural secretions.

Aporrhi′psis. (From αποῤῥιπτω, to cast off.) Hippocrates uses this word to signify that kind of insanity where the patient tears off his clothes, and casts them from him.

Aposceparni′smus. (From απο, from, and σκεπαρνιζω, to strike with a hatchet.) *Deasciatio.* A species of fracture, when part of a bone is chipped of. *Gorræus.*

Aposcha′sis. *Aposchasmus.* (From απο, and σχαζω, to scarify.) A scarification. Venesection. *Hippocrates.*

Aposi′tia. *Apositios.* (From απο, from, and σιτος, food.) A loathing of food. *Galen.*

Apospa′sma. (From αποσπαω, to tear off.) A violent, irregular fracture of a tendon, ligament, &c. *Galen.*

Aposphaceli′sis. (From απο, and σφακελος, a mortification.) Hippocrates uses this word to denote a mortification of the flesh in wounds, or fractures, caused by too tight a bandage.

Apo′stasis. (From απο, and ιϛημι, to recede from.)

1. An abscess, or collection of matter.

2. The coming away of a fragment of bone, by fracture.

3. When a distemper passes away by some outlet, Hippocrates calls it an *apostasis by excretion.*

4. When the morbific matter, by its own weight, falls and settles on any part, an *apostasis by settlement.*

5. When one disease turns to another, an *apostasis by metastasis.*

Aposta′xis. (From αποϛαζω, to distil from.) Hippocrates uses this word to express the defluxion or distillation of any humour, or fluid: as blood from the nose.

APOSTE′MA. (From αφιϛημι, to recede.) The term given by the antients to abscesses in general. See *Abscess.*

Apostema′tiai. Those who, from an inward abscess, void pus downwards, are thus called by Aretæus.

Aposteri′gma. (From αποϛηριζω, fulcio.) Galen uses this word to denote a rest of a diseased part, a cushion.

Apostolo′rum ungue′ntum. (From αποστολος, an apostle.) *Dodecapharmacum.* The apostles' ointment; so called because it has twelve ingredients in it, exclusive of the oil and vinegar.

Apo′strophe. (From απο and ϛρεφω, to turn from.) Thus Paulus Ægineta expresses an aversion for food.

Aposyringe′sis. (From απο and συριγξ, a fistula.) The degeneracy of a sore into a fistula. *Hippocrates.*

Aposy′rma. (From απο and συρω, to rub off.) An abrasion or desquamation of the bones or skin. *Hippocrates.*

Apotaneu′sis. (From απο and τεινω, to extend.) An extension, or elongation, of any member or substance.

Apotelme′sis. (From απο and τελμα, a bog.) An expurgation of filth, or fæces.

Apothe′ca. (Αποθηκη: from αποτιθημι, to reposit.) A shop, or vessel, where medicines are sold, or deposited.

APOTHECA′RIUS. (From απο, and τιθημι, *pono,* to put; so called from his employ being to prepare, and keep in readiness, the various articles in the *Materia Medica,* and to compound them for the physician's use; or from αποθηκη, a shop.) An apothecary. In every European country, except Great Britain, the *apothecary* is the same as, in England, we name the *druggist* and *chemist.*

Apotherapei′a. (From απο and ϑεραπευω, to cure.) A perfect cure, according to Hippocrates.

Apotherapeu′tica. (From αποϑεραπευω, to heal.) Therapeutics; that part of medicine which teaches the art of curing disorders.

Apothe′rmum. (From απο and ϑερμη, heat.) An acrimonious pickle, with mustard, vinegar, and oil. *Galen.*

Apo′thesis. (From απο and τιθημι, to replace.) The reduction of a dislocated bone, according to Hippocrates.

Apothli′mma. (From απο and ϑλιϐω, to press from.) The dregs or expressed juice of a plant.

Apothrau′sis. (From απο and ϑραυω, to break.) Apocope. The taking away the splinters of a broken bone.

Apo′tocus. (From απο and τικτω, to bring forth.) Abortive; premature. *Hippocrates.*

Apotre′psis. (From απο and τρεπω, to turn from.) A resolution or reversion of a suppurating tumour.

Apotropæ′a. (From αποτρεπω, to avert.) An amulet, or charm, to avert diseases. *Foësius.*

A′pozem. *Apozema.* (From απο and ζεω, to boil.) A decoction.

Apozeu′xis. (From ἀπο and ζευγνυμι, to separate.) The separation or removal of morbid parts. *Hippocrates.*

Apo′zymos. (From απο and ζυμη, ferment.) Fermented.

APPARA′TUS. (From *appareo,* to appear, or be ready at hand.) This term is applied to the instruments and the preparation and arrangement of every thing necessary in the performance of any operation surgical or chemical.

Appara′tus, chemical. See *Chemical apparatus.*

Appara′tus, pneumatic. See *Pneumatic apparatus.*

Appara′tus mi′nor. See *Lithotomy.*

Appara′tus ma′jor. See *Lithotomy.*

Appara′tus a′ltus. See *Lithotomy.*

Appendi′cula cæ′ci vermifo′rmis. A vermicular process, about four inches in length, and the size of a goose-quill, which hangs to the intestinum cæcum of the human body.

Appendi′culæ epiplo′icæ. *Appendices coli adiposæ.* The small appendices of the colon and rectum, which are filled with adipose substance. See *Omentum.*

Apple, thorn. See *Datura.*

Apple. See *Pyrus.*

Apricot. See *Prunus armeniaca.*

APYRE′XIA. (From α, priv. and πυρεξια, a fever.) Apyrexy. Without fever. The intermission of feverish heat.

A′QUA. See *Water.*

A′qua a′eris fi′xi. Water impregnated with fixed air. This is liquid carbonic acid, or water impregnated with carbonic acid; it sparkles in the glass, has a pleasant acidulous taste, and forms an excellent beverage. It diminishes thirst, lessens the morbid heat of the body, and acts as a powerful diuretic. It is also an excellent remedy in increasing irritability of the stomach, as in advanced pregnancy, and it is one of the best anti-emetics which we possess.

A′qua alu′minis compo′sita. Compound solution of alum, formerly called aqua aluminosa bateana. See *Liquor aluminis compositus.*

A′qua ammo′niæ aceta′tæ. See *Ammoniæ acetatis liquor.*

A′qua ammo′niæ pu′ræ. See *Ammonia.*

A′qua ane′thi. See *Anethum.*

A′qua ca′lcis. See *Calcis liquor.*

A′qua cœle′stis. A preparation of cuprum.

A′qua ca′rui. See *Carum.*

A′qua cinnamo′mi. See *Laurus cinnamomum.*

A′qua cu′pri ammonia′ti. See *Cupri ammoniati liquor.*

A′qua cu′pri vitriola′ti compo′sita. This preparation of the Edinburgh Pharmacopœia, is used externally, to stop hæmorrhages of the nose, and other parts. It is made thus:

℞. *Cupri vitriolati, Aluminis, sing.* ℥ss. *Aquæ puræ,* ℥iv. *Acidi vitriolici,* ʒij.

Boil the salts in water until they are dissolved; then filter the liquor, and add the acid.

A′qua distilla′ta. Distilled water. This is made by distilling water in clean vessels, until about two-thirds have come over. In nature, no water is found perfectly pure. Spring or river water always contains a portion of saline matter, principally sulphate of lime: and, from this impregnation, is unfit for a number of pharmaceutic preparations. By distillation, a perfectly pure water is obtained. The London College directs ten gallons of common water; of which, first distil four pints, which are to be thrown away; then distil four gallons. This distilled water is to kept in glass vessels. See *Water.*

A′qua fœni′culi. See *Anethum fœniculum.*

A′qua fo′rtis. See *Nitric acid.*

A′qua ka′li præpara′ti. See *Potassæ subcarbonatis liquor.*

A′qua ka′li pu′ri. See *Potassæ liquor.*

A′qua litha′rgyri aceta′ti. See *Plumbi subacetatis liquor.*

A′qua litha′rgyri aceta′ti compo′sita. See *Plumbi subacetatis liquor dilutus.*

A′qua me′nthæ piperi′tæ. See *Mentha piperita.*

A′qua me′nthæ sati′væ. See *Mentha viridis.*

A′qua me′nthæ vir′idis. See *Mentha viridis.*

A′qua pime′ntæ. See *Myrtus Pimenta.*

A′qua pule′gii. See *Mentha Pulegium.*

A′qua re′gia. *Aqua regalis.* The acid now called the nitro-muriatic, was formerly called aqua regalis, because it was, at that time, the only acid that was known to be able to dissolve gold. See *Nitro-muriatic acid.*

A′qua ro′sæ. See *Rosa centifolia.*

A′qua sty′ptica. A name formerly given to a combination of powerful astringents, viz. sulphate of copper, sulphate of alum, and sulphuric acid. It has been applied topically to check hæmorrhage, and, largely diluted with water, as a wash in purulent ophthalmia. See *Aqua cupri vitriolati composita.*

A′qua zi′nci vitriola′ti cum ca′mphora. Otherwise named *Aqua vitriolica camphorata.* It was made by dissolving half an ounce of sulphate of zinc in a quart of boiling water, adding half an ounce of camphorated spirit, and filtering. This, when properly diluted, is an useful collyrium for inflammations of the eyes, in which there is a weakness of the parts. Externally it is applied by surgeons to scorbutic and phagedenic ulcerations.

A′quæ distilla′tæ. Distilled waters. These are made by introducing vegetables, as mint, penny-royal, &c. into a still with water; and drawing off as much as is found to possess the properties of the plants. The London College orders the waters to be distilled from dried herbs, because fresh are not ready at all times of the year. Whenever the fresh are used, the weights are to be increased. But whether the fresh or dried herbs are employed, the operator may vary the weight according to the season in which they have been produced and collected. Herbs and seeds, kept beyond the space of a year, are improper for the distillation of waters. To every gallon of these waters, five ounces, by measure, of proof spirit are to be added.

A′quæ minera′les. See *Mineral waters.*

A′quæ stillati′tiæ si′mplices. Simple distilled waters.

A′quæ stillati′tiæ spirituo′sæ. Spirituous distilled waters, now called only spiritus, as spiritus pulegii.

Aquæduct of Fallopius. A canal in the petrous portion of the temporal bone, first accurately described by Fallopius.

Aquatic nut. See *Trapa natans.*

Aqueous humour of the eye. The very limpid watery fluid, which fills both chambers of the eye. See *Eye.*

Aque′tta. The name of a liquid poison, made use of by the Roman women, under the Pontificate of Alexander VII. It was prepared, and sold in drops, by Tophania, or Toffania, an infamous woman who resided at Palermo, and afterwards at Naples. From her, these drops obtained the name of *Aqua Toffania, Aqua della Toffana,* and also *Aqua di Napoli.* This poison is said, by some, to be a composition of arsenic, and by others of opium and cantharides.

Aquifo′lium. (From *acus,* a needle, and *folium,* a leaf; so called on account of its prickly leaf. See *Ilex.*

A′quila. A chemical name formerly used for sal-ammoniac, mercurius præcipitatus, arsenic, sulphur, and the philosopher's stone.

A′quila a′lba. One of the names given to calomel by the antients. See *Submurias hydrargyri.*

A′quila a′lba philosopho′rum. *Aqua alba ganymedis.* Sublimed sal-ammoniac.

A′quila cœle′stis. A panacea, or cure for all diseases; a preparation of mercury.

A′quila ve′neris. A preparation of the antients, made with verdigrise and sublimed sal-ammoniac.

A′quila, among the antients, had many other epithets joined with it, as rubra, salutifera, volans, &c.

A′quilæ ve′næ. (From *aquila,* an eagle.) Branches of the jugular veins, which are particularly prominent in the eagle.

A′quilæ li′gnum. Eagle-wood. It is generally sold for the agallochum.

AQUILE′GIA. (From *aqua,* water, and *lego,* to gather; so called from the shape of its leaves, which retain water.) The herb columbine.

1. The name of a genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Pentagynia.*

2. The name, in the Pharmacopœias, for the columbine. See *Aquilegia vulgaris.*

Aquile′gia vulga′ris. The systematic name of the columbine. The seeds, flowers, and the whole plant, have been used medicinally, the first in exanthematous diseases, the latter chiefly as an antiscorbutic. Though retained in several foreign pharmacopœias, their utility seems to be not allowed in this country.

Aquu′la. (Diminutive of *aqua.*) A small quantity of very fine and limpid water. This term is applied to the pellucid water, which distends the capsule of the crystalline lens, and the lens itself. Paulus Ægineta uses it to denote a tumour consisting of a fatty substance under the skin of the eyelid.

Arabic gum. See *Acaciæ gummi.*

A′racalan. Amulets.

A′raca mi′ri. (Indian.) A shrub growing in the Brazils, whose roots are diuretic and antidysenteric.

Ara′chne. (From *arag,* Heb. to weave; or from *αϱαχνη,* a spider.) The spider.

ARACHNOID MEMBRANE. (From *αραχνη,* a spider, and *ειδος,* likeness; so named from its resemblance to a spider's web.) A thin membrane of the brain, without vessels and nerves, situated between the dura and pia mater, and surrounding the cerebrum, cerebellum, medulla oblongata, and medulla spinalis. The term is also applied by some writers to the tunic of the crystalline lens and vitreous humour of the eye.

Arack. (Indian.) An Indian spirituous liquor, prepared in many ways, often from rice; sometimes from sugar, fermented with the juice of cocoa-nuts; frequently from toddy, the juice which flows from the cocoa-nut tree by incision, and from other substances.

A′rados. (From *αϱαδεω,* to be turbulent.) Hippocrates uses this term to signify a commotion in the stomach, occasioned by the fermentation of its contents.

Aræo′tica. (From *αϱαιοω,* to rarefy.) Things which rarefy the fluids of the body.

Ara′lia. (From *ara,* a bank in the sea; so called because it grows upon banks, near the sea.) The berry-bearing angelica. Of the several species of this tree, the roots of the nudicaulis, or naked-stalked, were brought over from North America, where it grows, and sold here for sarsaparilla.

Ara′nea. (From *αϱαω,* to knit together.) The spider.

ARA′NTIUS, Ju′lius Cæsar, a celebrated anatomist and physician, born at Bologna, about the year 1530. After studying under Vesalius, and others, he graduated and became professor there, and died in 1589. In his first work, "On the Human Fœtus," he described the foramen ovale, and ductus arteriosus; and corrected several errors in the anatomy of the gravid uterus, which had been generally derived from the examination of brutes. He afterwards shewed that the blood, after birth, could only pass from the right to the left side of the heart through the vessels of the lungs, thus preparing for the discovery of the circulation by Harvey. A Treatise on Tumours, and a Commentary on Part of Hippocrates, were also written by him.

A′RBOR VI′TÆ. The tree of life.

1. The cortical substance of the cerebellum is so disposed, that, when cut traversely, it appears ramified like a tree, from which circumstance it is termed *arbor vitæ*.

2. The name of a tree formerly in high estimation in medicine. See *Thuya occidentalis*.

ARBUTHNOT, John, a physician, born in Scotland soon after the Restoration, celebrated for his wit and learning. He graduated at Aberdeen, and settling in this metropolis, had the good fortune to be at Epsom, when Prince George of Denmark was taken ill there; whom, having restored to health, he was appointed physician to Queen Anne, but never got into very extensive practice. His chief medical publications were "On the Choice of Aliments," and "On the Effects of Air upon Human Bodies." He died in 1735.

A′RBUTUS. The name of a genus of plants in the Linnæan system. Class, *Decandria*. Order, *Monogynia*. The strawberry tree.

A′rbutus une′do. *Amatzquitl. Unedo papyracea.* A decoction of the bark of the root of this plant is commended in fevers.

A′rbutus u′va u′rsi. The systematic name for the officinal trailing arbutus. Bear's berry, bear's whortle-berry, bear's whorts, or bear's bilberries, called also *vaccaria-vaccinia*. *Arbutus canlibus procumbentibus, foliis integerrimis* of Linnæus. This plant, though employed by the antients in several diseases, requiring adstringent medicines, had almost entirely fallen into disuse until the middle of the present century, when it first drew the attention of physicians, as a useful remedy in calculous and nephritic complaints, which diseases it appears to relieve by its adstringent qualities.

A′rca arcano′rum. The mercury of the philosophers.

A′rca co′rdis. The pericardium.

ARCA′NUM. (A secret.) A medicine whose preparation, or efficacy, is kept from the world, to enhance its value. With the chemists, it is a thing secret and incorporeal; it can only be known by experience, for it is the virtue of every thing, which operates a thousand times more than the thing itself.

Arca′num catho′licum. Bezoar, plantain, and colchicum.

Arca′num du′plex. *Arcanum duplicatum.* A name formerly given to the combination of potash and sulphuric acid, more commonly called vitriolated tartar, and now sulphate of potash.

Arca′num ta′rtari. The acetate of potash.

Arce′uthos. Juniper.

Archæ′us. The universal archæus, or principle of Van Helmont, was the active principle of the material world; it means good health also.

A′rche. (From αρχη, the beginning.) The earliest stage of a disease.

Arche′nda. (Arab.) A powder made of the leaves of the ligustrum, to check the fœtid odour of the feet. Detergent.

Archeo′stis. White briony.

Archima′gia. (From αρχη, the chief, and *maga*, Arab. meditation.) Chemistry, as being the chief of sciences.

Archi′tholus. (From αρχη, the chief, and ϑολος, a chamber.) The sudatorium, or principal room of the antient baths.

A′rchos. (From αρχος, an arch.) The anus; so called from its shape.

Archopto′ma. (From αρχος, the anus, and ϖιπτω, to fall down.) A bearing down of the rectum, or prolapsus ani.

Arcta′tio. (From *arcto*, to make narrow.) *Arctitudo*. Narrowness.

1. A constipation of the intestines, from inflammation.

2. A preternatural straitness of the pudendum muliebre.

A′RCTIUM. (From αρκτος, a bear; so called from its roughness.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*. Order, *Polygamia æqualis*. The burdock.

A′rctium la′ppa. (*Lappa*; απο τȣ λαϐειν, from its seizing the garments of passengers.) The herb clot bur, or burdock. The systematic name for the *bardana*. *Arctium. Betonica. Britannica. Ilaphis.* The plant so called in the pharmacopœias, is *Arctium lappa*: —*foliis cordatis, inermibus, petiolatis*, of Linnæus. It grows wild in uncultivated grounds. The seeds have a bitterish subacrid taste: they are recommended as very efficacious diuretics, given either in the form of emulsion, or in powder, to the quantity of a drachm. The roots taste sweetish, with a slight austerity and bitterness: they are esteemed aperient, diuretic, and sudorific; and are said to act without irritation, so as to be safely ventured upon in acute disorders. Decoctions of them have of late been used, in rheumatic, gouty, venereal, and other disorders; and are preferred by some to those of sarsaparilla. Two ounces of the roots are to be boiled in three pints of water, to a quart; to this, two drachms of sulphate of potash have been usually added. Of this decoction, a pint should be taken every day in scorbutic and rheumatic cases, and when intended as a diuretic, in a shorter period.

Arctu′ra. (From *arcto*, to straiten.) An inflammation of the finger, or toe, from a curvature of the nail. *Linnæus.*

Arcua′lia. (From *arcus*, a bow.) *Arcualis.* The sutura coronalis is so named, from its bow-like shape; and, for the same reason, the bones of the sinciput are called arcualia ossia. *Bartholin.*

Arcua′tio. (From *arcus*, a bow.) A gibbosity of the fore-parts, with a curvation of the sternum of the tibia, or dorsal vertebræ. *Avicenna.*

A′rculæ. (A dim. of *arca*, a chest.) The orbits or sockets of the eyes.

A′rdas. (From αϱδυω, to defile.) Filth, excrement, or refuse. *Hippocrates.*

Ardent Spirit. See *Alkohol.*

A′rdor febri′lis. Feverish heat.

A′rdor uri′næ. *Dysuria.* Scalding of the urine. Difficulty and pain in making water, attended with a sense of heat in the urethra. It is a symptom of gonorrhœa, and some other affections.

A′rdor ventri′culi. Heartburn.

A′rea. An empty space. That kind of baldness where the crown of the head is left naked, like the tonsure of a monk.

Are′ca i′ndica. An inferior kind of nutmeg.

Are′gon. (From αϱηγω, to help.) A resolvent ointment; so called from its valuable qualities.

Arema′ros. Cinnabar.

Are′na. Sand, or gravel.

Arena′mel. (From *arena*, sand; so called because it was said to be procured from sandy places.) *Arenamen.* Bole-armenic.

Arena′tio. (From *arena*, sand.) Saburration, or the sprinkling of hot sand upon the bodies of patients. *Andr. Baccius de Therm.*

Are′ntes. (From *areo*, to dry up.) A sort of antient cupping-glasses, used without scarifying.

ARE′OLA. (A dim. of *area*, a void space.) A small brown circle, which surrounds the nipples of females. During and after pregnancy, it becomes considerably larger.

Aretænoi′des. See *Arytænoides.*

ARETÆ′US, of Cappadocia, a physician, who practised at Rome, but at what period is uncertain, though the most probable opinion places him between the reigns of Vespasian and Adrian. Eight books of his remain "On the Causes, Signs, and Method of treating acute and chronic Diseases," written in the Greek language, and admired for their pure style, and luminous descriptions, as well as the judicious practice generally recommended. He was partial to the use of hellebore and other drastic medicines; and appears to have been among the first to recommend cantharides for blistering the skin.

A′rete. (Αϱετη, virtue.) Hippocrates uses this word to mean corporeal or mental vigour.

Are′us. A pessary, invented by Ægineta.

A′rfar. *Arsag.* Arsenic. *Ruland*, &c.

A′rgal. Argol. Crude tartar, in the state in which it is taken from the inside of wine-vessels, is known in the shops by this name.

Argasy′llis. (From αϱγος, a serpent; which it is said to resemble.) The plant which was supposed to produce gum ammoniac.

A′rgema. (From αϱγος, white.) *Argemon.* A small white ulcer of the globe of the eye. *Erotianus. Galen*, &c.

Arge′nti ni′tras. *Causticum lunare. Argentum nitratum.* Nitrate of silver. "Take of silver an ounce; nitric acid, a fluid-ounce; distilled water, two fluid-ounces. Mix the nitric acid and water, and dissolve the silver therein on a sand bath; then increase the heat gradually that the nitrate of silver may be dried. Melt the salt in a crucible over a slow fire until the water being evaporated, it shall cease to boil; then pour it quickly into moulds of convenient shape." Its virtues are corrosive and astringent. Internally it is exhibited in very small quantities, in epilepsy; and externally it is employed to destroy fungous excrescences, callous ulcers, fistulas, &c. In the latter disease it is employed as an injection; from two grains to three being dissolved in an ounce of distilled water.

ARGE′NTUM. Silver. See *Silver.*

Arge′ntum nitra′tum. See *Nitras argenti.*

Arge′ntum vi′vum. It was formerly, by some, called argentum mobile, and argentum fusum. See *Mercury.*

A′rges. (From αϱγος, white.) A serpent, with a whitish skin, deemed by Hippocrates exceedingly venomous.

Argi′lla. (From αϱγος, white.) White clay; argil; potters' earth.

Argi′lla vitriola′ta. Alum.

Argyri′tis. (From αϱγυϱος, silver.) Litharge, or spume of silver. A kind of earth was formerly so named, which is taken from silver mines, and is bespangled with many particles of silver.

Argyro′come. (From αϱγυϱος, silver, and κομη, hair.) A sort of cudweed, or gnaphalium, was so named from its white silvery floscules.

Argyroli′banos. The white-olibanum.

Argyro′phora. An antidote, in the composition of which there is silver.

Argyrotrophe′ma. (From αϱγος, white, and τϱοφημα, food.) A white cooling food, made with milk. Milk diet. *Galen.*

Arheumati′stos. (From *α*, neg. and *ῥευματιζω*, to be afflicted with rheums.) Not being afflicted with gouty rheums.

Aricy′mon. (From *αρι*, and *κυω*, to be quickly impregnated.) A woman who conceives quickly and often.

Aristalthæ′a. (From *αριϛος*, best, and *αλθαια*, the althæa.) Althæa, or common marsh-mallow.

ARISTOLO′CHIA. (From *αριστος*, good, and *λοχια*, or *λοχεια*, parturition; so called because it was supposed to be of sovereign use in disorders incident to child-birth.) 1. The name of a genus of plants in the Linnæan system. Class, *Gynandria*. Order, *Hexandria*. Birthwort.

2. The pharmacopœial name of the long-rooted birthwort. See *Aristolochia longa*.

Aristolo′chia anguici′da. Snake-killing birthwort. *Aristolochia:—foliis cordatis, acuminatis; caule volubili, fruticoso; pedunculis solitariis; stipulis cordatis*, of Linnæus. The juice of the root of this plant has the property of so stupifying serpents, that they may be handled with impunity. One or two drops are sufficient; and if more be dropt into the mouth, they become convulsed. So ungrateful is the smell of the root to those reptiles, that it is said they immediately turn from it. The juice is also esteemed as a preventive against the effects usually produced by the bite of venomous serpents.

Aristolo′chia clemati′tis. (*Clematitis*, from *κλημα*, a tendril; from its climbing up trees, or any thing it can fasten upon with its tendrils.) *Aristolochia tenuis*. The systematic name of the *Aristolochia vulgaris* of some pharmacopœias. An extract is ordered by the Wirtemberg Pharmacopœia, and the plant is retained in that of Edinburgh. It is esteemed as possessing antipodagric virtues.

Aristolo′chia faba′cea. See *Fumaria bulbosa*.

Aristolo′chia lo′nga. The systematic name for the aristolochia of our pharmacopœias. *Aristolochia foliis cordatis, petiolatis, integerrimis, obtusiusculis; caule infirmo, floribus solitariis.* The root of this plant only is in use; it possesses a somewhat aromatic smell, and a warm bitterish taste, accompanied with a slight degree of pungency. The virtues ascribed to this root by the antients were very considerable; and it was frequently employed in various diseases, but particularly in promoting the discharge of the *lochia*; hence its name. It is now very rarely used, except in gouty affections, as an aromatic stimulant.

Aristolo′chia rotu′nda. The root of this species of birthwort, *Aristolochia foliis cordatis, subsessilibus, obtusis; caule infirmo; floribus solitariis* of Linnæus; is used indiscriminately with that of the *aristolochia longa*. See *Aristolochia longa*.

Aristolo′chia serpenta′ria. The systematic name for the *Serpentaria virginiana* of the pharmacopœias. *Colubrina virgineana. Viperina virgineana. Aristolochia. Pestilochia. Contrayerva virgineana.* Virginian snake-root. The plant which affords this root is the *Aristolochia foliis cordato oblongis planis, caulibus infirmis flexuosis teretibus, floribus solitariis. Caulis geniculata valde nodosa. Flores ad radicem* of Linnæus. Snake-root has an aromatic smell, approaching to that of valerian, but more agreeable; and a warm, bitterish, pungent taste. It was first recommended as a medicine of extraordinary power in counteracting the poisonous effects of the bites of serpents; this, however, is now wholly disregarded: but as it possesses tonic and antiseptic virtues, and is generally admitted as a powerful stimulant and diaphoretic, it is employed, in the present day, in some fevers where these effects are required. A *tinctura serpentariæ* is directed both by the London and Edinburgh Pharmacopœias.

Aristolo′chia te′nuis. See *Aristolochia clematitis*.

Aristolo′chia triloba′ta. Three-lobed birthwort. The root, and every part of this plant, *Aristolochia foliis trilobis, caule volubili, floribus maximis* of Linnæus; is diuretic, and is employed in America against the bite of serpents.

Aristolo′chia vulga′ris. See *Aristolochia clematitis*.

Aristophanei′on. (From *Aristophanes*, its inventor.) The name of an antient emollient plaster, composed of wax, or pitch. *Gorræus*.

Armatu′ra. Harness. The amnios or internal membrane which surrounds the fœtus.

A′rmæ. (From *αρω*, to adapt.) A junction of the lips of wounds; also the joining of the sutures of the head.

Armi′lla. (Dim. of *armus*, the arm.) The round ligament which confines the tendons of the carpus.

Armora′cia. (From *Armorica*, the country whence it was brought.) See *Cochlearia Armoracia*.

Armora′ciæ ra′dix. Horse-radish root. See *Cochlearia Armoracia*.

ARMSTRONG, John, a Scotch physician, born in 1709, who, after graduating at Edinburgh, settled in London, but met with little success, having distinguished himself less in his profession than as a poet, particularly by his "Essay on the Art of preserving Health" in blank verse. He afterwards attended the army in Germany, which brought him more into notice as a physician. He attained the age of seventy, and died in pretty good circumstances. His professional publications are not of much note; the principal one is entitled "Medical Essays." He is supposed, however, to have contributed materially to a useful Treatise on the Diseases of Children, published by his brother George, who after practising many years as an apothecary obtained a diploma in medicine.

A'RNICA. (Αρνικη: from αρς, a lamb; because of the likeness of the leaf of this plant to the coat of the lamb.) Leopard's-bane. Arnica.

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia superflua.*

2. The pharmacopœial name of the Mountain arnica.

A'rnica monta'na. The systematic name for the *arnica* of the pharmacopœias. *Arnica foliis ovatis integris; caulinis geminis oppositis* of Linnæus. *Doronicum Germanicum.* The flowers of this plant are very generally employed on the Continent. Of the advantages derived from their use, in paralytic and other affections, depending upon a want of nervous energy, there are several proofs; and their extraordinary virtues, as a febrifuge and antiseptic, have been highly extolled by Dr. Collin, of Vienna. Much caution is necessary in regulating the dose, as it is a medicine very apt to produce vomiting and much uneasiness of the stomach. See *Arnica.*

A'rnica Suede'nsis. See *Inula dysenterica.*

Arno'tto. (Spanish.) A curious shrub in Jamaica, the seeds of which are covered with a kind of wax, from which is made the Spanish arnotto.

ARO'MA. (*Aroma, matis,* neut. from αρι, intensely, and οζω, to smell.) *Spiritus rector.* Each plant has its characteristic smell. This odorant principle is called, by the moderns, *aroma.* Water charged with aroma, is called the distilled water of the substance made use of; thus lavender and peppermint waters are water impregnated with the aroma of the lavender and peppermint.

Aroma'ticus co'rtex. A name for canella alba.

AROMA'TICS. (*Aromatica,* sc. *medicamenta;* from αρωμα, an odour.) A term applied to all medicines which have a grateful spicy scent, and an agreeable pungent taste, as cinnamon bark, cardamoms, &c. Their peculiar flavour appears to reside in their essential oil, and arises in distillation either with water or spirit.

Aromatopo'la. (From αρωμα, an odour, and πωλεω, to sell.) A druggist; a vender of drugs and spiceries.

Arquebusa'de. (A French word, implying *good for a gun-shot wound.*) *Aqua sclopetaria. Aqua vulneraria. Aqua catapultarum.* The name of a spirituous water, distilled from a farrago of aromatic plants.

Arra'ck. A spirituous liquor distilled from rice, and drank, in the rice countries, as brandy is in this Island. Its effects on the animal economy are the same.

A'rraphus. (From α, priv. and ραφη, a suture.) Without suture. It is applied to the cranium when naturally without sutures.

Arrhæ'a. (From α, neg. and ρεω, to flow.) The suppression of any natural flux, as the menses, &c.

ARROWHEAD. The roots of this plant, *Sagittaria sagittifolia* of Linnæus, are said to be esculent, but it must be in times of very great scarcity.

ARROW-ROOT. See *Maranta.*

ARSE'NIAS. (From *arsenicum,* arsenic.) An arseniate or arsenical salt. A salt formed by a combination of arsenic acid with different bases, as arseniate of ammonia, which is produced by the union of ammonia with arsenic acid. The only one used in medicine is the superarseniate of potash. See *Arsenic Acid.*

A'RSENIC. (From the Arabic term *Arsanek,* or from αρσην, for αρρην, *masculus;* from its strong and deadly powers.)

Arsenic is a metal scattered, in great abundance, over the mineral kingdom. It is found in black heavy masses of little brilliancy, called *native arsenic,* (testaceous arsenic.) This exists in different parts of Germany. Mineralised by sulphur, it forms *sulphurised arsenic.* This mineral is met with in Italy, about Mount Vesuvius. — There are two varieties of this ore, which differ from each other in colour, occasioned by the different proportions of their component parts. The one is called yellow *sulphurised arsenic,* or *orpiment;* the other, *red sulphurised arsenic,* or *realgar,* (*ruby arsenic*); both are met with in Hungary and different parts of Germany. The colour of the first ore is a lemon-yellow, inclining sometimes to a green; the colour of the latter is a ruby-red; it is more transparent than the former, and found in compact solid masses, sometimes crystallized in bright needles. Arsenic united to oxygen, constitutes the ore called *native oxide of arsenic.* This ore is scarce; it is generally found of an earthy appearance, or as an efflorescence, coating native, or metallic arsenic; its colour is a whitish-grey; it is rarely met with crystallized. Arsenic exists likewise alloyed with cobalt, antimony, tin, copper, lead, and various other metals.

Properties. — Arsenic is a brittle metal, and in the recent fracture, of a lively bright colour, between tin-white and lead-grey; but, on exposure to the air, it soon loses its metallic lustre, becoming dull, and at last black. Its specific gravity is between 8.310 and 5.763, according to its texture or purity. Its hardness surpasses that of copper; but its ductility is inconsiderable, and its brittleness so great, that it is readily converted into a powder by the hammer. It is entirely volatilised when heated to 356° Fahr. It sublimes in close vessels, and then crystallizes in tetrahedra, or octahedra. When heated with the access of air, it emits a strong smell of garlic, and burns with a blueish-white flame, being converted to a white oxide. It combines with sulphur by fusion. It unites to phosphorus, and combines with most of the metals. It gives a white colour to copper, and renders many of the ductile metals brittle. When mixed with hyper-oxygenated muriate of potash, it detonates strongly by the stroke of a hammer. It is soluble in hydrogen gas by heat. It does not decompose water alone. If it be kept under water, its metallic brilliancy may be preserved. This effect is still better produced by alcohol. It decomposes sulphuric acid by heat. The nitric and nitrous acids oxidate it rapidly. The muriatic acid attacks it with heat. The oxygenated muriatic acid, when in a gaseous state, inflames it instantly. It is nearly unalterable by the fluoric, boracic, phosphoric, and carbonic acids. It unites with alkaline sulphurets, and hydro-sulphurets.

Method of obtaining Arsenic.— In order to obtain metallic arsenic, mix two parts of the white oxide of arsenic of commerce, with one of black flux (obtained by detonating one part of nitrate of potash with two of supertartrate of potash), and put the mixture into a crucible, or melting-pot. Invert over this, another crucible, lute the two together with a little clay and sand, and apply gradually a red heat to the lower one. The oxide of arsenic will be reduced, and be found lining the upper crucible in small crystals of a metallic brilliancy.

The charcoal of the black flux takes in this process the oxygen from the white oxide, and forms carbonic acid gas; which flies off during the process, and the oxide becomes reduced to the metallic state. This reduction of the oxide is greatly facilitated by the alkali of the flux.

Remark.— In order to obtain arsenic in a state of absolute purity, the metal thus obtained must be reduced to a powder, dissolved by heat in nitro-muriatic acid, and then precipitated by immersing into the solution a plate of zinc. The arsenic is thus precipitated in a fine powder, and may be reduced to a mass, by exposing it in a covered crucible to a moderate heat.

Arsenic and its various preparations are the most active of all poisons. That which is mostly taken, is the white oxide, or arsenious acid, to which the following observations apply. A nausea, sickness, and retching, commonly ensue in half an hour after taking it, followed by violent vomitings, hiccups, and pains in the stomach and bowels; convulsions and palsies of the limbs presently succeed, with intense heats, cold sweats, palpitations of the heart, extrême anxiety, prostration of strength, thirst, and dryness of the mouth and throat; loss of reason, and at last death. If the quantity taken has been considerable, the stomach and intestines are often found, upon dissection, corroded, or perforated, and the blood is fluid; though in general the patient expires before the action of the poison has proceeded to such a length. After death, the body runs into sudden putrefaction. When the quantity taken does not prove fatal, it occasions tremors, palsies, or lingering hectics, and in the end death. To detect the presence of arsenic, whether taken by design, the wickedness of others, or imprudence, it is recommended by some to throw on live coals, the contents of the stomach, when a garlicky smell will be immediately obvious. In the stomach, however, there may be many substances, which resemble or disguise the smell of arsenic, especially if the arsenic be in small quantities. We are therefore advised by Hahneman, to boil the contents of the stomach of the person supposed to be destroyed by this poison, in a large quantity of river water; to add to one-third of the filtered liquor, hot and limpid lime-water; to another third, water saturated with sulphuretted hydrogen gas; and to the remainder, a solution of copper, in pure aqua ammoniæ. Each fluid is rendered turbid, if the suspected contents contain arsenic; and the sediment, thrown on live coals, emits the odour of garlic. The white sediment from the lime-water is again dissolved by a recent solution of arsenic; the lemon-coloured sediment, from the sulphuretted hydrogen water thrown on the coals, takes fire, and the smell of sulphur is observed previous to that of garlic; while the yellow-green sediment from the solution of copper is soluble in pure ammonia, and acids of every kind. Another very minute test of the arsenious acid is nitrate of silver, producing a yellow precipitate from the solution, particularly if a little potash or ammonia be previously added, to neutralise the acid. But it must be borne in mind, that nitrate of silver produces a similar precipitate from a solution of phosphate of soda. Indeed no single mode of trial should be relied upon, as we cannot be sure but that some other substance might be similarly affected, where no arsenic is present; and farther, because where arsenic is present many substances will prevent the usual precipitates, or render them of a different colour. It should be remembered also, that the whole of the poison may have been discharged by vomiting, and therefore any matters rejected from the stomach ought to be examined in the same way. If any white substance can be collected, having the appearance of arsenious acid, it will be proper to mix part of it with about the same bulk of charcoal and a little oil; put the mixture between two plates of bright copper, and expose the whole to a faintly red heat; the copper will be changed to a silvery whiteness on its inner surface, supposing arsenic present. But a more important step is to obtain the metal separate.

Any substance suspected to be arsenious acid, or any of the precipitates above mentioned, should be mixed with about the same bulk of finely powdered charcoal and subcarbonate of potash (or of the black flux), the mixture put into a glass tube closed at the bottom, taking care that the part above is quite clean, then partially close the orifice with a piece of paper, and expose the other end to a slight red heat; in a few minutes a brilliant metallic coating will appear on the inside of the tube above the materials introduced, on the supposition that arsenic was there. In all these modes of examination, the judgment will be much assisted by making comparative experiments with the substances suspected, and with what is known to be arsenious acid: as the coincidence is greater, the stronger will be our conviction, that the person had actually taken that poison.

The treatment of poisoning by arsenic is very simple. The chief object is to procure its expulsion from the stomach as speedily and with as little irritation as possible. None of the various antidotes that have been recommended can be depended upon. If the practitioner were consulted before vomiting had come on, it would be proper to attempt to excite that act, by giving a quantity of warm water, and irritating the fauces with a feather; or even exhibiting a mild emetic, as ipecacuanha, unless there were violent pain at the stomach. But in general, before advice is sought, the vomiting has become so severe, that all we can do is by giving repeated large draughts of diluent and demulcent liquids, as water, milk, linseed infusion, or whatever can be most readily procured to render it less painful, and facilitate the thorough evacuation of the poison. It is necessary to remember, that butter, oils, &c. though ranked with demulcents, have been found even injurious, accelerating the fatal event in experiments on animals. Should inflammation supervene in any part of the alimentary canal, marked especially by much pain on pressure, it will be requisite to adopt the antiphlogistic plan; taking blood from the arm, if the habit of the patient will allow it, but particularly applying from ten to twenty leeches over the part affected; then the warm bath may be directed, or fomentations, if the pressure can be borne; likewise copious mucilaginous glisters, &c. If on the other hand, after the discharge of the poison, marks of disturbance of the nervous system appear urgent, antispasmodic or sedative remedies will be indicated, but especially opium. Should the patient fortunately be brought to a state of convalescence, much will depend on a careful regulation of the diet; which should consist of milk, arrow-root, jellies, and other substances, which are nutritious, mild, and easy of digestion: taking care at the same time that the bowels be not confined. Sulphur combined with arsenic appears to lessen its activity; how far it can contribute to remove its effects is perhaps hardly determined by satisfactory experience; but it may certainly be given in small doses without impropriety. Notwithstanding the mischief it is capable of producing, the arsenious acid is a valuable internal remedy, in its appropriate dose, viz. about one-eighteenth part of a grain. See *Arsenicalis liquor*. Externally it is used as a caustic, particularly in cancer.

ARSENIC ACID. This is arsenic fully oxygenated. It is always a product of art.

It is capable of existing in the solid state. It appears in the form of a white pulverulent matter. It attracts humidity from the air. It is soluble in water. The solution possesses a considerable acid taste. It may be evaporated to dryness, and even converted into glass. It is decomposable by all combustible bodies, and by many oxides. It is soluble in some acids, but without change, or intimate combination.

Method of obtaining Arsenic Acid.—Take two ounces of white arsenic in powder, and put it into a tubulated retort; pour on it six or seven ounces of muriatic acid, and apply the heat of a lamp until the arsenious acid is dissolved. Then add three or four ounces of nitric acid, and heat it again gradually. An intestine motion now takes place, and much red vapour, or nitrous gas, is extricated. As soon as in the progress of the operation, the red vapours have ceased, an ounce of finely powdered arsenious acid is to be again added, and the solution effected as before, by a gentle ebullition; to this two ounces of nitric acid must be added, which will produce a second effervescence and discharge of red vapours: the distillation must now be continued to dryness, and the fire must be urged towards the end, to such a degree, as to make the residual mass thoroughly red hot. This mass is arsenic acid, which may either be preserved in that form, or be dissolved in boiling distilled water.

Arsenic acid, united to different bases, forms saline compounds, called ARSENIATES. The only one used in medicine is the superarseniate of potash, which see.

ARSE'NICAL CAUSTIC. A species of caustic said to possess useful properties, independent of those of destroying morbid parts to which it is applied. It is composed of two parts of levigated antimony to one of white arsenic. This is the caustic so extensively employed under the name of arsenical caustic, by the late Mr. Justamond, in his treatment of cancers.

ARSENICA'LIS LI'QUOR. Arsenical solution. "Take of sublimed oxide of arsenic, in very fine powder, subcarbonate of potash from tartar, of each 64 grains; distilled water a pint. Boil them together in a glass vessel, until the arsenic be entirely dissolved. When the solution is cold, add compound spirit of lavender, four fluid-drachms. Then add as much distilled water as may exactly fill a pint measure." This preparation accords with the formula of Dr. Fowler, of Stafford, who first introduced it in imitation of a celebrated popular remedy for intermittents, sold under the name of the tasteless ague-drop. The compound spirit of lavender is only intended to give some colour and taste, without which it would be more liable to mistakes. Where the dose is small, and the effects so powerful, the most minute attention to its proportion and preparation become necessary. Each ounce contains four grains of the oxide, and each drachm half a grain; but it will rarely be proper to go beyond one-sixteenth of a grain as a dose.

Arsenical solution. See *Arsenicalis liquor.*

Arse'nici o'xydum sublima'tum. *Arsenici oxydum præparatum.* This is intended to render the arsenious acid more pure. It is directed to be powdered, put into a crucible, and sublimed by the application of fire into another crucible inverted over the first.

Arsénici óxydum præparátum. See *Arsenici oxydum sublimatum.*

Arsénicum álbum. White arsenic. See Arsenious acid in the article *Arsenic.*

ARSE'NIOUS ACID. White arsenic. Oxide of arsenic. *Arsenicum crystallinum, risagallum, aquala, arfar, aquila, zarnick, artaneck.* Rat's bane. The earliest chemists were embarrassed in the determination of the nature of the poisonous white substance known in commerce by the name of *white arsenic.* Subsequent experiments have shewn that this substance is metallic arsenic oxygenated in the first degree, but possessing the characters of an acid. The name of *arsenious acid* is therefore given to it. It is sometimes found in nature in sublimed crystals, in volcanoes; and in masses, or in stalactites among the ores of arsenic, cobalt, bismuth, and nickel.

It possesses a weak sub-acid taste, which slowly manifests itself. Though of but a feeble acidity, it sensibly reddens the tincture of cabbage and litmus. If placed on burning coals, or on a red-hot iron, it is volatilised in the form of a white vapour, which has a strong smell of garlic. It is slightly soluble in water. With phosphoric and boracic acids it fuses into glass. It decomposes the nitrates and the super-oxygenated muriate of potash. It unites with many of the earths and alkalies, as well as metallic oxides, and forms saline compounds, which are termed arsenites.

Methods of obtaining Arsenious Acid. — 1. Pulverise arsenic, and put as much of it into a Florence flask as will fill it about one half, or less. Introduce a little tow, or cotton, into the neck of the flask, and apply the heat of a lamp. A dense white smoke will be formed, and become precipitated on the internal sides of the flask. If the process be kept up till all the arsenic be oxidated, (which may be known by introducing a wire into the flask for a moment, which will become covered with a white crust, if the sublimation be not completed,) and the heat be then gradually augmented, the sublimed arsenious acid undergoes a sort of fusion, and an opaque white mass, similar to that met with in commerce, is obtained.

2. The arsenious acid of the shops (or white arsenic) is chiefly obtained from arsenical ores of cobalt. These ores are thrown into a furnace, resembling a baker's oven, with a long flue, or chimney, either horizontal or winding, into which the fumes pass, and are condensed into a greyish or blackish powder. This is refined by a second sublimation, in close vessels, with a little alkali to arrest the impurities. As the heat is considerable, it melts the sublimed arsenious acid into those opaque crystalline masses which are known in commerce by the name of white arsenic.

ARTEMI'SIA. (From a queen of that name, who first used it; or from Αρτεμις, Diana; because it was formerly used in the diseases of women, over whom she presided.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia superflua.*

Artemi'sia abro'tanum. The systematic name for the *abrotanum* of the pharmacopœias. *Abrotanum mas. Abrathan.* Common southern-wood.

Artemisia fruticosa, of Linnæus: —*foliis setaceis ramosissimis.* A plant possessed of a strong and, to most people, an agreeable smell; a pungent, bitter, and somewhat nauseous taste. It is supposed to stimulate the whole system, but more particularly the uterus. It is very rarely used unless by way of fomentation, with which intention the leaves are directed.

Artemi'sia absi'nthium. The systematic name for the *Absinthium vulgare* of the pharmacopœias. Common wormwood. Falsely called in our markets *Absinthium Romanum*, or Roman wormwood. *Absinthium Ponticum* of Dioscorides and Pliny, according to *Murray. Artemisia foliis compositis multifidis floribus subglobosis pendulis: receptaculo villoso* of Linnæus. This plant is a native of Britain, and grows about rubbish, rocks, and sides of roads. The leaves of wormwood have a strong disagreeable smell: their taste is nauseous, and so intensely bitter as to be proverbial. The flowers are more aromatic and less bitter than the leaves, and the roots discover an aromatic warmth, without bitterness. This species of wormwood may be considered the principal of the herbaceous bitters. Its *virtus*, in the words of Bergius, is antiputredinosa, antacida, anthelmintica, resolvens, tonica, spasmodica. And, although it is now chiefly employed with a view to the two last-mentioned qualities, yet we are told of its good effects in a great variety of diseases, as intermittent fevers, hypochondriasis, obstructions of the liver and spleen, gout, calculi, scurvy, dropsy, worms, &c. See Woodville's Medical Botany. Cullen thinks it is possessed of a narcotic power, and that there is in every bitter, when largely employed, a power of destroying the sensibility and irritability of the nervous system.

Externally, wormwood is used in discutient and antiseptic fomentations. This plant may be taken in powder, but it is more commonly preferred in infusion. The Edinburgh Pharmacopœia directs a tincture of the flowers, which is, in the opinion of Dr. Cullen, a light and agreeable bitter, and, at the same time, a strong impregnation of the wormwood.

Artemi′sia chine′nsis. *Moxa Japonica. Musia pattræ. Moxa.* Mugwort of China. A soft lanuginous substance, called moxa, is prepared in Japan, from the young leaves of this species of mugwort, by beating them when thoroughly dried, and rubbing them betwixt the hands, till only the fine fibres are left. Moxa is celebrated in the eastern countries for preventing and curing many disorders, by being burnt on the skin; a little cone of it laid upon the part, previously moistened, and set on fire on the top, burns down with a temperate and glowing heat, and produces a dark-coloured spot, the ulceration of which is promoted by putting a little garlic, and the ulcer is either healed up when the eschar separates, or kept running for a length of time, as different circumstances may require.

Artemi′sia juda′ica. The systematic name for the *Santonicum* of the pharmacopœias, according to some botanists. See *Artemisia Santonica.*

Artemi′sia mari′tima. The systematic name for the *Absinthium maritimum* of the pharmacopœias. Sea wormwood, falsely called in our markets, Roman wormwood. *Artemisia: foliis multipartitis, tomentosis; racemis cernuis; flosculis fœmineis ternis* of Linnæus. This plant grows plentifully about the sea-shore, and in salt marshes. The specific differences between it and the common wormwood, artemisia absinthium, are very evident. Its taste and smell are considerably less unpleasant than those of the common wormwood, and even the essential oil, which contains the whole of its flavour concentrated, is somewhat less ungrateful, and the watery extract somewhat less bitter than those of the common wormwood. Hence it is preferred, in those cases where the artemisia absinthium is supposed to be too unpleasant for the stomach. A conserve of the tops of this plant was directed by the London Pharmacopœia.

Artemi′sia po′ntica. The systematic name for the *Absinthium ponticum*, or Roman wormwood, not now used medicinally.

Artemi′sia rupe′stris. The systematic name for the *genipi album* of the pharmacopœias. *Artemisia:—foliis pinnatis; caulibus adscendentibus; floribus globosis, cernuis; receptaculo papposo.* It has a grateful smell, and is used in some countries in the cure of intermittents and obstructed catamenia.

Artemi′sia santo′nica. *Absinthium santonicum Alexandrinum. Sementina. Absinthium seriphium Ægyptium. Scheba Arabum. Zedoariæ sem. Xantolina. Lumbricorum semina. Cina. Semen contra. Semen sanctum.* The Tartarian southern-wood or wormseed, *Artemisia: foliis caulinis linearibus, pinnato-multifidis; ramis indivisis; spicis secundis reflexis; floribus quinquefloris* of Linnæus. The seeds are small, light, and oval, composed of a number of thin membranous coats of a yellowish-green colour, with a cast of brown, easily friable, upon being rubbed between the fingers, into a fine chaffy kind of substance. They are brought from the Levant; have a moderately strong and not agreeable smell, somewhat of the wormwood kind, and a very bitter subacrid taste. Their virtues are extracted both by watery and spirituous menstrua. They are esteemed to be stomachic, emmenagogue, and anthelmintic; but it is especially for the last-mentioned powers that they are now administered, and from their efficacy in this way they have obtained the name of wormseed. To adults the dose in substance is from one to two drachms, twice a-day. Lewis thinks that the spirituous extract is the most eligible preparation of the santonicum, for the purposes of an anthelmintic.

Artemi′sia vulga′ris. Mugwort. This plant, *Artemisia:—foliis pinnatifidis, planis, incisis, subtus tomentosis; racemis simplicibus, recurvatis; floribus radio quinquefloro* of Linnæus, is slightly bitter, and, although in high esteem in former days, is now almost wholly forgotten.

Artemo′nium. (From *Artemon*, its inventor.) A collyrium, or wash for the eyes.

ARTE′RIA. See *Artery.*

Arteri′aca. (From *αϱτηϱια*, an artery.) Medicines formerly used against disorders of the aspera arteria, or trachea.

Arte′riæ adipo′sæ. The arteries which secrete the fat about the kidneys are so called. They are branches of the capsular and diaphragmatic, renal, and spermatic arteries.

Arte′riæ veno′sæ. The four pulmonary veins were so called by the antients.

Arterio′sus du′ctus. See *Ductus arteriosus.*

ARTERIO′TOMY. (From *αϱτηϱια*, an

artery, and τεμνω, to cut.) The opening of an artery. This operation is only performed on the temporal artery.

A'RTERY. (From αηρ, air, and τηρεω, to keep; so called because the antients supposed that only air was contained in them.) *Arteria.* Arteries are membranous pulsating canals, which gradually become less as they proceed from the heart. They are composed of three membranes; a common, or external; a muscular; and an internal one, which is very smooth. They originate from the heart; the pulmonary artery from the right ventricle, and the aorta from the left: the other arteries are all branches of the aorta. Their termination is either in the veins, or in capillary exhaling vessels, or they anastomose with one another. It is by their means that the blood is carried from the heart to every part of the body, for nutrition, preservation of life, generation of heat, and the secretion of the different fluids. The action of the arteries, called the pulse, corresponds with that of the heart, and is effected by the contraction of their muscular, and great elasticity of their outermost coat.

A Table of the Arteries.

All the arteries originate from the pulmonary artery and the aorta.

The *pulmonary artery* emerges from the right ventricle of the heart, soon divides into a right and left branch, which are distributed by innumerable ramifications through the lungs.

The *aorta* arises from the left ventricle of the heart, and supplies every part of the body with blood, in the following order:

a. It first forms an *arch;*
b. It then descends along the spine, and
c. It divides into the two *iliacs.*

a. The ARCH OF THE AORTA gives off three branches.

1. The *arteria innominata,* which divides into the *right carotid* and *right subclavian.*
2. The *left carotid.*
3. The *left subclavian.*

I. The *carotids* are divided into *external* and *internal.*

The *external carotids* give off,

1. The *thyroid,*
2. The *lingual,*
3. The *labial,*
4. The *inferior pharyngeal,*
5. The *occipital,*
6. The *posterior auris,*
7. The *internal maxillary,* from which the *spinous artery of the dura mater,* the *lower maxillary,* and *several branches about the palate and orbit* arise,
8. The *temporal.*

The *internal carotid* affords,

1. The *ophthalmic,*
2. The *middle cerebral,*
3. The *communicans,* which inosculates with the *vertebral.*

II. The *subclavians* give off the following branches:

1. The *internal mammary,* from which the *thymic, comes phrenici, pericardiac,* and *phrenico-pericardiac arteries* arise,
2. The *inferior thyroid,* which gives off the *tracheal, ascending thyroid,* and *transversalis humeri,*
3. The *vertebral,* which proceeds within the vertebræ, and forms within the cranium the *basilary artery,* from which the *anterior cerebelli,* the *posterior cerebri,* and *many branches about the brain* are given off,
4. The *cervicalis profunda,*
5. The *cervicalis superficialis,*
6. The *superior intercostal,*
7. The *supra-scapular.*

As soon as the subclavian arrives at the arm-pit, it is called the *axillary artery;* and when the latter reaches the arm, it is called the *brachial.*

The *axillary artery* gives off,

1. *Four mammary arteries,*
2. The *sub-scapular,*
3. The *posterior circumflex,*
4. The *anterior circumflex,* which ramify about the shoulder-joint.

The *brachial artery* gives off,

1. *Many lateral branches,*
2. The *profunda humeri superior,*
3. The *profunda humeri inferior,*
4. The *great anastomosing artery,* which ramifies about the elbow-joint;

The *brachial artery* then divides, about the bend of the arm, into the *ulnar* and *radial arteries,* which are ramified to the ends of the fingers.

The *ulnar artery* gives off,

1. *Several recurrent branches,*
2. The *common interosseal,* of which the *dorsal ulnar,* the *palmaris profunda,* the *palmary arch,* and the *digitals,* are branches.

The *radial artery* gives off,

1. The *radial recurrent,*
2. The *superficialis volæ,* and then divides into the *palmaris profunda,* and the *digitals.*

b. The DESCENDING AORTA gives off,

In the breast,

1. The *bronchial,*
2. The *œsophageal,*
3. The *intercostals,*
4. The *inferior diaphragmatic;*

Within the abdomen,

1. The *cœliac;* which divides into three branches:
    1. The *hepatic,* from which are given off, before it reaches the liver,
        α. The *duodeno-gastric,* which sends off the *right gastro-epiploic* and the *pancreatico-duodenal,*
        β. The *pylorica superior hepatica;*
    2. The *coronaria ventriculi,*
    3. The *splenic,* which emits the *great* and *small pancreatics,* the *posterior gastric,* the *left gastro-epiploic,* and the *vasa brevia;*

2. The *superior mesenteric,*
3. The *emulgents,*
4. The *spermatics,*
5. The *inferior mesenteric,*
6. The *lumbar arteries,*
7. The *middle sacral.*

c. The aorta then bifurcates into the ILIACS, each of which divide into *external* and *internal.*

The *internal iliac,* called also *hypogastric,* gives off,

1. The *lateral sacrals,*
2. The *gluteal,*
3. The *ischiatic,*
4. The *pudica,* rom which the *external hæmorrhoidal,* the *perineal,* and the *arteriæ penis* arise,
5. The *obturatory.*

The *external iliac* gives off, in the groin,

1. The *epigastric,*
2. The *circumflexa iliaca;*

It then passes under Poupart's ligament, and is called the *femoral artery;* and sends off,

1. The *profunda,*
2. The *ramus anastomoticus magnus,* which runs about the knee-joint;

Having reached the ham, where it gives off some small branches, it is termed the *popliteal.* It then divides into the *anterior* and *posterior tibial.*

The *tibialis antica* gives off,

1. The *recurrent,*
2. The *internal malleolar,*
3. The *external malleolar,*
4. The *tarsal,*
5. The *metatarsal,*
6. The *dorsalis externa halicis.*

The *posterior tibial* sends off,

1. The *nutritia tibiæ,*
2. *Many small branches,*
3. The *internal plantar,*
4. The *external plantar,* from which an *arch* is formed, that gives off the *digitals of the toes.*

ARTHANI'TA. (From αρτος, bread; because it is the food of swine.) The herb sow-bread. See *Cyclamen.*

ARTHRE'MBOLUS. (From αρθρον, a joint, and εμβαλλω, to impel.) An instrument for reducing luxated bones.

ARTHRI'TICA. (From αρθριτις, the gout.) 1. The herb ground-pine; so called because it was thought good against gouty disorders.

2. Remedies for the gout.

ARTHRI'TIS. (*-tidis,* fœm. from αρθρον, a joint; because it is commonly confined to the joints.) The gout. Dr. Cullen, in his Nosology, gives it the name of *podagra,* because he considers the foot to be the seat of idiopathic gout. It is arranged in the class *pyrexiæ,* and order *phlegmasiæ,* and is divided into four species, the regular, atonic, retrocedent, and misplaced. The gout is a very painful disease, preceded usually by flatulency and indigestion, and accompanied by fever, pains in the joints of the hands and feet, particularly in that of the great-toe, and which returns by paroxysms, occurring chiefly in the spring and beginning of winter. The only disorder for which the regular gout can possibly be mistaken, is the rheumatism; and cases may occur wherein there may be some difficulty in making a just discrimination: but the most certain way of distinguishing them will be, to give due consideration to the predisposition in the habit, the symptoms which have preceded, the parts affected, the recurrences of the disease, and its connection with other parts of the system. Its attacks are much confined to the male sex, particularly those of a corpulent habit, and robust body; but every now and then we meet with instances of it in robust females. Those who are employed in constant bodily labour, or who live much upon vegetable food, as likewise those who make no use of wine, or other fermented liquors, are seldom afflicted with the gout. The disease seldom appears at an earlier period of life than from five-and-thirty to forty; and, when it does, it may be presumed to arise from an hereditary disposition. Indolence, inactivity, and too free a use of tartareous wines, fermented liquors, and animal food, are the principal causes which give rise to the gout; but it may likewise be brought on by great sensuality and excess in venery, intense and close application to study, long want of rest, grief, or uneasiness of mind, exposure to cold, too free a use of acidulated liquors, a sudden change from a full to a spare diet, the suppression of any accustomed discharge, or by excessive evacuations; and that it sometimes proceeds from an hereditary disposition, is beyond all doubt, as females who have been remarked for their great abstemiousness, and youths of a tender age, have been attacked with it.

1. *Arthritis regularis.* A paroxysm of regular gout sometimes comes on suddenly, without any previous warning; at other times it is preceded by an unusual coldness of the feet and legs, a suppression of perspiration in them, and numbness, or a sense of prickling along the whole of the lower extremities; and with these symptoms the appetite is diminished, the stomach is troubled with flatulency and indigestion, a degree of torpor and languor is felt over the whole body, great lassitude and fatigue are experienced after the least exercise, the body is costive, and the urine pallid. On the night of the attack, the patient perhaps goes to bed in tolerable health, and after a few hours, is awaked by the severity of the pain, most commonly in the first joint of the great-toe; sometimes, however, it attacks other parts of the foot, the heel, calf of the leg, or perhaps the whole of the foot. The pain resembles that of a dislocated bone, and is attended with the sensation as if cold water was poured upon the part; and th

pain becoming more violent, is succeeded by rigors and other febrile symptoms, together with a severe throbbing and inflammation in the part. Sometimes both feet become swelled and inflamed, so that neither of them can be put to the ground; nor can the patient endure the least motion, without suffering excruciating pain. Towards morning, he falls asleep, and a gentle sweat breaks out, and terminates the paroxysm, a number of which constitutes what is called a fit of the gout; the duration of the fit will be longer or shorter, according to the disposition of the body to the disease, the season of the year, and the age and strength of the patient. When a paroxysm has thus taken place, although there is an alleviation of pain at the expiration of some hours, still the patient is not entirely relieved from it; and, for some evenings successively, he has a return both of pain and fever, which continue, with more or less violence, until morning. The paroxysms, however, prove usually more mild every day, till at length the disease goes off either by perspiration, urine, or some other evacuation; the parts which have been affected becoming itchy, the cuticle falling off in scales from them, and some slight degree of lameness remaining. At first, an attack of gout occurs, perhaps, only once in two or three years; it then probably comes on every year, and, at length, it becomes more frequent, and is more severe, and of longer duration, each succeeding fit. In the progress of the disease various parts of the body are affected, and translations take place from one joint, or limb, to another; and, after frequent attacks, the joints lose their strength and flexibility, and become so stiff as to be deprived of all motion. Concretions, of a chalky appearance, are likewise formed upon the outside of the joints, and nephritic affections of the kidneys arise from a deposit of the same kind of matter in them, which, although fluid at first, becomes gradually dry and firm. This matter is partly soluble in acids, but without effervescence; and Dr. Wollaston discovered it not to be carbonate of lime, but a compound of the uric or lithic acid and soda.

2. *Arthritis atonica.* Atonic gout. It sometimes happens that, although a gouty diathesis prevails in the system, yet, from certain causes, no inflammatory affection of the joints is produced; in which case, the stomach becomes particularly affected, and the patient is troubled with flatulency, indigestion, loss of appetite, eructations, nausea, vomiting, and severe pains; and these affections are often accompanied with much dejection of spirits, and other hypocondriacal symptoms. In some cases, the head is affected with pain and giddiness, and now and then with a tendency to apoplexy; and in other cases, the viscera of the thorax suffer from the disease, and palpitations, faintings, and asthma arise. This is what is called atonic gout.

3. *Arthritis retrograda.* Retrocedent gout. It sometimes happens that, after the inflammation has occupied a joint, instead of its continuing the usual time, and so going off gradually, it ceases suddenly, and is translated to some internal part. The term retrocedent gout is applied to occurrences of this nature. When it falls on the stomach, it occasions nausea, vomiting, anxiety, or great pain; when on the heart, it brings on syncope; when on the lungs, it produces an affection resembling asthma; and, when it occupies the head, it is apt to give rise to apoplexy, or palsy.

4. *Arthritis aberrans,* or misplaced gout, is when the gouty diathesis, instead of producing the inflammatory affection of the joints, occasions an inflammatory affection of some internal part, and which appears from the same symptoms that attend the inflammation of those parts from other causes. All occurrences of this nature, as well as of the two former, are to be regarded as attacks of irregular gout, and are to be guarded against as much as possible.

In the regular gout generally little medical interference is necessary: the antiphlogistic regimen should be observed, in proportion to the strength of the patient, the bowels kept regular, and the part of a moderate temperature, by covering it with flannel, &c.: it may be useful too to promote a gentle diaphoresis. In young and robust constitutions, where there is no hereditary tendency to the disease, and the inflammation and fever run high, more active evacuations may sometimes be required: and, on the contrary, in persons advanced in life, who have suffered much from the disease, and been accustomed to a generous diet, this must be in some degree allowed even during the paroxysm to obviate a metastasis; recommending fish in preference to other animal food, and madeira as the least acescent wine. The application of cold to the part is a dangerous practice; and it is better to abstain from any local measures, lest the favourable progress of the disease should be interrupted. When the paroxysm is terminated, any remaining stiffness of the joint will probably be gradually removed by friction, &c. With respect to the means of obviating future attacks, the chief dependance is to be placed on abstemiousness, with regular moderate exercise. Proper medicines may be occasionally prescribed to remove any dyspeptic symptoms, keep the bowels regular, the skin perspirable, &c. If the disease appear to hang about the patient in the atonic form, a more nutritious diet, with tonic or even stimulant medicines, may be required to re-establish the health, which will probably not be accomplished without a paroxysm intervening. The Bath waters have often been found useful under these circumstances. In the retrocedent gout the object is to bring back the inflammation to the joint as soon as possible: for which purpose a sinapism, or other stimulant application, should be put upon the part; while ammonia, aromatics, æther, warm wine, or brandy and water, &c. are administered internally, in proportion to the urgency of the symptoms; but in general the best form of medicine is the combination of opium with some of the stimulants just mentioned, unless where congestion appears in the head. Sometimes blisters or rubefacients may be properly applied over the internal part affected, where this is of importance to life, or even the local abstraction of blood become necessary. This however holds more especially where the attack is inflammatory, constituting the misplaced gout, and a more antiphlogistic plan must then be pursued; but evacuations cannot be borne to the same extent as in the idiopathic phlegmasiæ.

Arthroca′ce. (From *αϱθϱον*, a joint, and *κακη*, a disease.) An ulcer of the cavity of the bone.

ARTHRO′DIA. (From *αϱθϱοω*, to articulate.) A species of *diarthrosis*, or moveable connection of bones, in which the head of one bone is received into the superficial cavity of another, so as to admit of motion in every direction, as the head of the humerus with the glenoid cavity of the scapula.

ARTHRODY′NIA. (From *αρθρον*, a joint, and *οδυνη*, pain.) Chronic pains in the joints, without pyrexia. It is one of the terminations of acute rheumatism. See *Rheumatismus*.

ARTHROPUO′SIS. (From *αρθρον*, a joint, and *ϖυον*, pus.) *Arthropyosis*. A collection of pus in a joint. It is, however, frequently applied to other affections, as *lumbago psoadica*, &c.

Arthro′sis. (From *αρθϱοω*, to articulate, or join together.) Articulation.

Artichoke. See *Cinara*.

Artichoke, French. See *Cinara*.

Artichoke, jerusalem. See *Helianthus tuberosus*.

Articula′ris. A name given to a disease which more immediately infests the *articuli*, or joints. The morbus articularis is synonymous with the Greek word arthritis, and our gout. A branch of the basilic vein is called articularis vena, because it passes under the joint of the shoulder.

ARTICULATION. (From *articulus*, a joint.) The skeleton is composed of a great number of bones, which are all so admirably constructed, and with so much affinity to each other, that the extremity of every bone is perfectly adjusted to the end of the bone with which it is connected; and this connection is termed their articulation. Anatomists distinguish three kinds of articulation; the first they name Diarthrosis; the second, Synarthrosis; and the third, Amphiarthrosis; which see, under their respective heads.

Arti′scus. (From *αϱτος*, bread.) A troch; so called because they are made like little loaves.

Arto′creas. (From *αϱτος*, bread, and *κϱεας*, flesh.) A nourishing food, made of bread and various meats, boiled together. *Galen*.

Arto′gala. (From *αϱτος*, bread, and *γαλα*, milk.) A cooling food made of bread and milk. A poultice.

Arto′meli. (From *αϱτος*, bread, and *μελι*, honey.) A cataplasm made of bread and honey. *Galen*.

A′RUM. (From the Hebrew word *jaron*, which signifies a dart; so named because its leaves are shaped like a dart; or from *αρα*, injury.)

1. The name of a genus of plants in the Linnæan system. Class, *Gynandria*. Order, *Polyandria*. Arum, or wake-robin.

2. The pharmacopœial name of the common arum, or wake-robin.

A′rum dracu′nculus. The systematic name of the plant called in English dragon's wort, and many-leaved arum. *Dracunculus polyphyllus*. *Colubrina dracontia*. *Erva de Sancta Maria*. *Gigarus serpentaria*. *Arum polyphyllum*. The roots and leaves of this plant are extremely acrimonious, more so than the arum maculatum, with which it agrees in medicinal virtues.

A′rum macula′tum. The systematic name for the *arum* of the pharmacopœias. *Arum: acaule; foliis hastatis, integerrimis; spadice clavato* of Linnæus. The root is the medicinal part of this plant, which, when recent, is very acrimonious; and, upon being chewed, excites an intolerable sensation of burning and prickling in the tongue, which continues for several hours When cut in slices and applied to the skin, it has been known to produce blisters. This acrimony, however, is gradually lost by drying, and may be so far dissipated by the application of heat, as to leave the root a bland farinaceous aliment. In this state, it has been made into a wholesome bread. It has also been prepared as starch. Its medicinal quality, therefore, resides wholly in the active volatile matter, and consequently the powdered root must lose much of its power, on being long kept. Arum is certainly a powerful stimulant, and, by promoting the secretions, may be advantageously employed in cachectic and chlorotic cases, in rheumatic affections, and in various other complaints of phlegmatic and torpid constitutions; but more especially in a weakened or relaxed state of the stomach, occasioned by the prevalence of viscid mucus. If this root is given in powder, great care should be taken that it be young and newly dried, when it may be used in the dose of a scruple, or more, twice a day; but in rheumatisms, and other disorders requiring the full effect of this medicine, the root should be given in a recent state; and, to cover the insupportable pungency it discovers on the tongue, Dr. Lewis advises us to administer it in the form of emulsion, with gum-arabic and spermaceti, increasing the dose from ten grains to upwards of a scruple, three or four times a day. In this way, it generally occasioned a sensation of slight warmth about the stomach, and afterwards, in the remoter parts, manifestly promoted perspiration, and frequently produced a plentiful sweat. Several obstinate rheumatic pains were removed by this medicine. The root answers quite as well as garlic for cataplasms, to be applied on the feet in deliriums. The London College, in their pharmacopœia, 1788, ordered a conserve, in the proportion of half a pound of the fresh root to a pound and a half of double refined sugar, beat together in a mortar, which appears to be one of the best forms of exhibiting arum, as its virtues are destroyed by drying, and are not extracted by any menstruum. It may be given to adults in doses of a drachm.

ARYTÆ'NO-EPIGLOTTIDE'US. Innes. Albinus. *Arytæno-Epiglottici* of Winslow. A muscle composed of a number of fibres running between the arytænoid cartilage and epiglottis. It pulls the side of the epiglottis towards the external opening of the glottis, and when both act, they pull it close upon the glottis.

ARYTÆNOID CARTILAGE. *Cartilago arytænoidea.* The name of two cartilages of the larynx. See *Larynx.*

ARYTÆNOI'DES. (From αρυταινα, a funnel, and ειδος, shape.) The name of some parts, from their being funnel-shaped.

Arytænoide'us major. See *Arytænoideus transversus.*

Arytænoide'us mi'nor. See *Arytænoideus obliquus.*

ARYTÆNOIDE'US OBLI'QUUS. Innes, Albinus, and Winslow. *Arytænoideus minor* of Douglas. A muscle of the glottis, which arises from the base of one arytænoid cartilage, and crossing its fellow, is inserted near the tip of the other arytænoid cartilage. It is a muscle that is occasionally wanting; but when present, and both muscles act, their use is to pull the arytænoid cartilages towards each other.

ARYTÆNOIDE'US TRANSVE'RSUS, of Innes, Albinus, Winslow. *Arytænoideus major* of Douglas. An azygos, or single muscle of the glottis, that arises from the side of one arytænoid cartilage, from near its articulation with the cricoid to near its tip. The fibres run across, and are inserted in the same manner into the other arytænoid cartilage. Its use is to shut the glottis, by bringing the two arytænoid cartilages, with their ligaments, nearer to each other.

ASAFŒ'TIDA. (*Asafœtida, æ, f.* from the Hebrew word *asa,* to heal.) See *Ferula.*

Asa'phatum. (From α, neg. and σαφης, clear.) An intercutaneous itch, generated in the pores, like worms with black heads: so called by reason of their minuteness: they are hardly visible.

Asa'phia. (From α, neg. and σαφης, clear.) A defect in utterance or pronunciation.

Asarabacca. See *Asarum.*

A'sari fo'lia. Asarabacca leaves. The leaves of the Asarum Europæum. See *Asarum.*

A'SARUM. (From α, neg. and σαιρω, to adorn; because it was not admitted into the antient coronal wreaths.) Asarabacca.

1. The name of a genus of plants in the Linnæan system. Class, *Dodecandria.* Order, *Monogynia.*

2. The pharmacopœial name of the asarabacca.

A'sarum Europæ'um. The systematic name of the asarabacca of the shops. *Asarum: foliis reniformibus, obtusis, binis* of Linnæus. It is a native of England, but not very common. The leaves of this plant are extremely acrid, and are occasionally used, when powdered, as a sternutatory. For this purpose the leaves, as being less acrid than the roots, are preferred, and in moderate doses not exceeding a few grains, snuffed up the nose, for several evenings, produce a pretty large watery discharge, which continues for several days together, by which head-ache, tooth-ache, ophthalmia, and some paralytic and soporific complaints have been effectually relieved.

Prior to the introduction of ipecacuanha, the leaves and root of this plant were frequently employed on account of their emetic power: the dose of the dried leaves was 20 grains; of the dried roots 10 grains. As they were occasionally violent in their operation, they have fallen into disuse. See *Asarum.*

Ascaloni'tis. A species of onion.

Asca'rides. The plural of *ascaris.* See *Ascaris.*

A'SCARIS. (From ασκεω, to move about; so called from its continued troublesome motion.) There are several kinds of worms distinguished by this term; but those which claim a place here, as belonging only to the human body, are: —

1. *Ascaris vermicularis, the thread* or *maw worm,* which is very small and slender, not exceeding half an inch in length; they inhabit the rectum.

2. *Ascaris lumbricoides, the long and round worm,* which is a foot in length, and about the breadth of a goose-quill.

Asce'ndens Obli'quus. See *Obliquus internus abdominis.*

A'scia. An axe or chissel. A simple bandage; so called from its shape in position. *Galen.*

ASCI'TES. (*Ascites, æ,* m. from ασκος,

a sack, or bottle; so called from its bottle-like protuberancy.) Dropsy of the belly. A tense, but scarcely elastic, swelling of the abdomen from accumulation of water. Cullen ranks this genus of disease in the class *cachexiæ*, and order *intumescentiæ*. He enumerates two species: —

1. *Ascites abdominalis*, when the water is in the cavity of the peritonæum, which is known by the equal swelling of the parietes of the abdomen.

2. *Ascites saccatus*, or encysted dropsy, in which the water is encysted, as in the ovarium; the fluctuation is here less evident, and the swelling is at first partial.

Ascites is often preceded by loss of appetite, sluggishness, dryness of the skin, oppression at the chest, cough, diminution of the natural discharge of urine, and costiveness. Shortly after the appearance of these symptoms, a protuberance is perceived in the hypogastrium, which extends gradually, and keeps on increasing, until the whole abdomen becomes at length uniformly swelled and tense. The distension and sense of weight, although considerable, vary somewhat according to the posture of the body, the weight being felt the most on that side on which the patient lies, whilst, at the same time, the distension becomes somewhat less on the opposite side. In general, the practitioner may be sensible of the fluctuation of the water, by applying his left hand on one side of the abdomen, and then striking on the other side with his right. In some cases, it will be obvious to the ear. As the collection of water becomes more considerable, the difficulty of breathing is much increased, the countenance exhibits a pale and bloated appearance, an immoderate thirst arises, the skin is dry and parched, and the urine is very scanty, thick, high-coloured, and deposits a lateritious sediment. With respect to the pulse, it is variable, being sometimes considerably quickened, and, at other times, slower than natural. The principal difficulty which prevails in ascites, is the being able to distinguish, with certainty, when the water is in the cavity of the abdomen, or when it is in the different states of encysted dropsy. To form a just judgment, we should attend to the following circumstances:—When the preceding symptoms give suspicion of a general hydropic diathesis; when, at the same time, some degree of dropsy appears in other parts of the body; and when, from its first appearance, the swelling has been equally diffused over the whole belly, we may generally presume that the water is in the cavity of the abdomen. But when an ascites has not been preceded by any remarkable cachectic state of the system, and when, at its beginning, the tumour and tension had appeared in one part of the belly more than another, there is reason to suspect an encysted dropsy. Even when the tension and tumour of the belly have become general, yet, if the system or the body in general appear to be little affected; if the patient's strength be little impaired; if the appetite continue pretty entire, and the natural sleep be little interrupted; if the menses in females continue to flow as usual; if there be yet no anasarca, or though it may have already taken place, if it be still confined to the lower extremities, and there be no leucophlegmatic paleness or sallow colour in the countenance; if there be no fever, nor so much thirst and scarcity of urine as occur in a more general affection: then according as more of these different circumstances take place, there will be the stronger grounds for supposing the ascites to be of the encysted kind. The encysted form of the disease scarcely admits of a perfect cure, though its progress to a fatal termination is generally very slow; and the peritoneal dropsy is mostly very obstinate, depending usually on organic disease in the liver, or other abdominal viscera. The plan of treatment agrees very much with that of *anasarca*; which see. The operation of paracentesis should only be performed where the distension is very great, and the respiration or other important functions impeded; and it will often be better not to draw off the whole of the fluid at once; great care must be taken too to keep up sufficient pressure, by a broad bandage over the abdomen; for even fatal syncope has arisen from the neglect of this. The contraction of the muscles will be promoted by friction. Cathartics are found more decidedly beneficial than in anasarca, where the bowels will bear their liberal use. Diuretics too are of great importance in the treatment; and, among other means of increasing the flow of urine, long-continued gentle friction of the abdomen with oil has been sometimes very successful, probably by promoting absorption in the first instance; the only use of the oil seems to be that the friction is thereby better borne. In cases where visceral obstructions have led to the effusion, these must be removed, before a cure can be accomplished: and for this purpose mercury is the remedy most to be depended upon, besides that, in combination with squill, or digitalis, it will often prove powerfully diuretic. Tonic medicines, a nutritious diet, and, if the complaint appears giving way, such exercise as the patient can take, without fatigue, with other means of improving the general health, ought not to be neglected.

ASCLEPI'ADES, a celebrated physician, born at Prusa, in Bithynia, who flourished somewhat before the time of Pompey. He originally taught rhetoric, but not meeting with success, applied himself to the study of medicine, in which he soon became famous from the novelty of his theory and practice. He supposed disease to arise from the motion of the particles of the blood and other fluids being obstructed by the straitness of the vessels, whence pain, fever, &c. ensued.

He deprecated the use of violent remedies, as emetics and purgatives, but frequently employed glysters, when costiveness attended. In fevers, he chiefly relied on a complete abstinence from food or drink for three days or more; but when their violence abated, allowed animal food and wine. In pleurisies, and other complaints attended with violent pain, he prescribed bleeding; but in those of a chronic nature, depended principally on abstinence, exercise, baths, and frictions. None of his works remain at present. He is said to have pledged his reputation on the preservation of his own health, which he retained to a great age, and died at length from a fall.

ASCLE'PIAS. (From *Asclepias*, its discoverer; or from *Æsculapius*, the god of medicine.) The herb swallow-wort. The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Digynia*.

Ascle'pias vinceto'xicum. The systematic name for the *vincetoxicum* of the pharmacopœias. *Hermidinaria. Asclepias.* Swallow wort. Tame poison. The root of this plant smells, when fresh, somewhat of valerian; chewed it imparts at first a considerable sweetness, which is soon succeeded by an unpleasant subacrid bitterness. It is given in some countries in the cure of glandular obstructions.

Ascle'pios. (From *Asclepias*, its inventor.) A dried smegma and collyrium described by Galen.

Asco'ma. (From ασκος, a bottle.) The eminence of the pubes at the years of maturity; so called from its shape.

A'sef. A pustule like a millet seed.

A'segon. *Asegen, Asogen.* Dragon's blood.

ASE'LLIUS, Gaspar, of Cremona, born about the year 1580, taught anatomy at Paris with great reputation. In 1622, he discovered the lacteals in a dog opened soon after a meal, and noticed their valves, but supposed they went to the liver. These vessels, he candidly observes, had been mentioned by some of the earliest medical writers, but not described, nor their function stated; and not being noticed by any modern anatomist previously, the discovery is properly attributed to him. His death took place four years after, subsequent to which his dissertation on the subject was published by his friends.

Ash. See *Fraxinus*.

Asia'ticum ba'lsamum. Balm of Gilead.

A'SINUS. The ass. Its milk is much esteemed in medicine. See *Asses' Milk*.

Asini'num lac. Asses' milk.

Asi'ti. (From α, neg. and σιτος, food.) *Asitia*. Those are so called who take no food, for want of appetite.

A'sjogam. (Indian.) A tree growing in Malabar and the East Indies, whose juice is used against the colic.

Aso'des. (From αδω, to nauseate.) A nausea or loathing, or a fever with much sense of heat and nausea. *Aretæus.*

Aspadia'lis. A suppression of urine from an imperforated urethra.

Aspa'lathum. The aromatic aloe.

Aspa'lathi lignum. See *Lignum Aloes.*

ASPA'RAGUS. (Ασπαϱαγος, a young shoot, before it unfolds its leaves.)

1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*. Order, *Monogynia*. Asparagus.

2. The pharmacopœial name of the common sparage, or sparrow-grass.

Aspa'ragus officinalis. The systematic name of the asparagus, the root of which has been esteemed as a diuretic. It is mostly employed as a food, but it contains very little nourishment.

Aspa'sia. (From α, for αμα, together, and σπαω, to draw.) A constrictive medicine for the pudendum muliebre. *Capivac.*

A'spera arte'ria. (So called from the inequality of its cartilages.) See *Trachea.*

ASPE'RULA. (A diminutive of *asper*, the seeds being rough.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria*. Order, *Monogynia*. Woodroof.

Aspe'rula odora'ta. The systematic name for the officinal *matrisylva*. It is a low umbelliferous plant, growing wild in woods and copses, and flowering in May. It hath an agreeable odour, which is much improved by moderate drying: the taste is a little austere. It imparts its flavour to vinous liquors; and is commended as a cordial and deobstruent remedy.

Asphalti'tis. A kind of trefoil: the last vertebra of the loins.

ASPHO'DELUS. (From ἀσπις, a serpent, and δειλος, fearful; because it destroys the venom of serpents; or from σποδελος, ashes, because it was formerly sown upon the graves of the dead.) Asphodel.

1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*. Order, *Monogynia*.

2. The pharmacopœial name of the daffodil, or branched asphodel.

Aspho'delus ramo'sus. The systematic name for the officinal *asphodelus*. — *Asphodelus: caule nudo; foliis ensiformibus, carinatis, lævibus*, of Linnæus. The plant was formerly supposed to be efficacious in the cure of sordid ulcers. It is now wholly laid aside.

ASPHY'XIA. (From α, priv. and σφυξις, a pulse.) The state of the body, during life, in which the pulsation of the heart and arteries cannot be perceived. There are several species of asphyxia enumerated by different authors. See *Syncope*.

Aspidi'scus. (From ασπις, a buckler.) The sphincter muscle of the anus was formerly so called from its shape. *Cœlius Aurelianus.*

ASPLE'NIUM. (From α, priv. and σπλην, the spleen; because it was supposed to remove disorders of the spleen.) The herb spleen-wort.

The name of a genus of plants in the Linnæan system. Class, *Cryptogamia.* Order, *Filices.*

Asple'nium ru'ta mura'ria. The systematic name for the *ruta muraria* of the pharmacopœias. It is supposed by some to possess specific virtues in the cure of ulcers of the lungs, and is exhibited in the form of decoction.

Asple'nium scolope'ndrium. The systematic name for the *scolopendrium* of the pharmacopœias. *Phillitis. Lingua cervina.* Harts-tongue. This indigenous plant, *Asplenium — frondibus simplicibus, cordato lingulatis, integerrimis; stipitibus hirsutis* of Linnæus: grows on most shady banks, walls, &c. It has a slightly astringent and mucilaginous sweetish taste. When fresh and rubbed, it imparts a disagreeable smell. Harts-tongue, which is one of the *five capillary* herbs, was formerly much used to strengthen the viscera, restrain hæmorrhages and alvine fluxes, and to open obstructions of the liver and spleen, and for the general purposes of demulcents and pectorals.

Asple'nium tricho'manes. The systematic name for the *trichomanes* of the pharmacopœias. Common maiden-hair, or spleen-wort. *Asplenium: frondibus pinnatis, pinnis subrotundis. crenatis* of Linnæus. This plant is admitted into the Edinburgh Pharmacopœia: the leaves have a mucilaginous, sweetish, subadstringent taste, without any particular flavour: they are esteemed useful in disorders of the breast, being supposed to promote the expectoration of tough phlegm, and to open obstructions of the viscera.

Assaba. A shrub found on the coast of Guinea, whose leaves are supposed to disperse buboes.

A'ssac. (Arab.) Gum ammoniacum.

Assafœ'tida. See *Ferula.*

A'ssala. The nutmeg.

A'ssanus. A weight consisting of two drachms.

Assaraba'cca. See *Asarum.*

Assa'rium. A Roman measure of twelve ounces.

Assarthro'sis. *Articulation.*

A'sse. A loathing of food, from a conflux of humours. *Hippocrates.*

Asses' milk. This is preferred to cows' and other kinds of milk, in phthisical cases, and where the stomach is weak; as containing less oleaginous particles, and being more easily converted into chyle.

Assimula'tion. (*Assimilatio*, from *ad*, and *similis*, to make like to.) The conversion of the food into nutriment.

Assiste'ntes. (From *ad*, and *sisto*, to stand near.) A name of the prostate glands, so called because they lie near the bladder.

Asso'des. (From ασαομαι, to nauseate, or from *assare*, to burn.) *Asodes.* A continual fever, attended with a loathing of food. Sauvages calls it Tritæophya assodes; it is arranged by Cullen under the tertian remittents.

A'ssos. A name given formerly to alumen.

A'stacus mari'nus. (From α, neg. and ςαζω, to distil; so called from the hardness and dryness of its shell.) The lobster. See *Cancer.*

A'stacus fluvia'tilis. The officinal crevis, or cray-fish. See *Cancer.*

A'stapis. (From ςαφις, uva passa.) A raisin.

Asta'rzof. The name of an ointment of litharge, house-leek, &c. *Paracelsus.*

Astchachilos. A malignant ulcer, by some called araneus.

Astera'ntium. (From αςηρ, a star.) *Astericum.* The herb pellitory; so called from its star-like form.

ASTHE'NIA. (From α, priv. and σθενος, strength.) Extreme debility. The asthenic diseases form one great branch of the Brunonian arrangement.

Asthenology. (From α, priv. and σθενος, strength, and λογος, a treatise.) The doctrine of diseases arising from debility. The disciples of the Brunonian school, as they denominate themselves, maintain peculiar opinions on this subject.

A'STHMA. (*Asthma, 'matis*, neut. from ασθμαζω, to breathe with difficulty.) Difficult respiration, returning at intervals, with a sense of stricture across the breast, and in the lungs; a wheezing, hard cough, at first, but more free towards the close of each paroxysm, with a discharge of mucus, followed by a remission. It is ranked by Cullen in the class *neuroses*, and order *spasmi.* There are three species of asthma: —

1. *Asthma spontaneum*, when without any manifest cause.

2. *Asthma plethoricum*, when it arises from plethora.

3. *Asthma exanthematicum*, originating from the repulsion of some acrid humour.

Asthma rarely appears before the age of puberty, and seems to attack men more frequently than women, particularly those of a full habit, in whom it never fails, by frequent repetition, to occasion some degree of emaciation. In some instances, it arises from an hereditary predisposition, and in many others, it seems to depend upon a particular constitution of the lungs. Dyspepsia always prevails, and appears to be a very prominent feature in the predisposition. Its attacks are most frequent during the heats of summer, in the dog-days, and in general commence about midnight. On the evening preceding an attack of asthma, the spirits are often much affected, and the person experiences a sense of fulness about the stomach, with lassitude, drowsiness, and a pain in the head. On the approach of the succeeding evening, he perceives a sense of tightness and stricture across the breast, and a sense of straitness in the lungs, impeding respiration. The difficulty of breathing continuing to increase for some length of time, both inspiration and expiration are performed slowly, and with a wheezing noise; the speech becomes difficult and uneasy, a propensity to coughing succeeds, and the patient can no longer remain in a horizontal position, being as it were threatened with immediate suffocation. These symptoms usually continue till towards the approach of morning, and then a remission commonly takes place; the breathing becomes less laborious and more full, and the person speaks and coughs with greater ease. If the cough is attended with an expectoration of mucus, he experiences much relief, and soon falls asleep. When he awakes in the morning, he still feels some degree of tightness across his breast, although his breathing is probably more free and easy, and he cannot bear the least motion, without rendering this more difficult and uneasy; neither can he continue in bed, unless his head and shoulders are raised to a considerable height. Towards evening, he again becomes drowsy, is much troubled with flatulency in the stomach, and perceives a return of the difficulty of breathing, which continues to increase gradually, till it becomes as violent as on the night before. After some nights passed in this way, the fits at length moderate, and suffer more considerable remissions, particularly when they are attended by a copious expectoration in the mornings, and this continues from time to time throughout the day; and the disease going off at last, the patient enjoys his usual rest by night, without further disturbance. The pulse is not necessarily affected in this disease, though often quickened by the difficulty of breathing; and sometimes slight pyrexia attends. In plethoric habits, the countenance is flushed and turgid during the fit; but in others rather pale and shrunk: in the former too, some difficulty of breathing and wheezing usually remain in the interval; in others, the recovery is more complete. On this is founded the common distinction of asthma into the humid, pituitous, or catarrhal, and the dry, spasmodic or nervous forms. The exciting causes are various: — accumulation of blood, or viscid mucus in the lungs, noxious vapours, a cold and foggy atmosphere, or a close hot air, the repulsion of eruptions, or other metastatic diseases, flatulence, accumulated fæces, violent passions, organic diseases in the thoracic viscera, &c. Sometimes the fits return at pretty regular periods; and it is generally difficult to obviate future attacks, when it has once occurred: but it often continues to recur for many years, and seldom proves fatal, except as inducing hydrothorax, phthisis, &c. The treatment must vary according to the form of the disease. In young persons of a plethoric habit, with great dyspnœa, a flushed countenance, accelerated pulse, &c. the abstraction of blood will be found to afford marked relief; but under opposite circumstances, it might be highly injurious, and we should always avoid repeating it unnecessarily. In ambiguous cases, cupping may be preferred, or leeches to the chest, with blisters. Mild cathartics should also be employed; or where costiveness appears to induce the fits, those of a more active nature. Nauseating emetics are of considerable service, especially where the patient is distressed with viscid mucus, not only by promoting perspiration and expectoration, but also by their antispasmodic power, the return of a paroxysm may often be prevented by their timely use. Squill combined with ipecacuanha is one of the best forms. Where the disease is of the purely spasmodic character, opium will be found the most powerful palliative remedy, especially if combined with ether, though it unfortunately loses of its power by repetition; the fetid gum resins are also useful, particularly where the bowels are torpid; and other antispasmodics may be occasionally employed. The practice of smoking, or chewing tobacco, has sometimes appeared extremely beneficial; and a cup of strong coffee has often afforded speedy relief. Means should also be employed for strengthening the system; and where there appears a tendency to serous effusion, digitalis may be very useful. But by far the most important part of the treatment consists in obviating or removing the several exciting causes, whether operating on the lungs immediately, or through the medium of the primæ viæ, &c. Individual experience can alone ascertain what state of the atmosphere as to temperature, dryness, purity, &c. shall be most beneficial to asthmatics, though a good deal depends on habit in this respect: but a due regulation of this, as well as of the diet, and other parts of regimen, will usually afford more permanent relief than any medicines we can employ.

A'STITES. (From *ad*, and *sto*, to stand near.) A name given by the antients to the prostate glands, because they are situated near the bladder.

ASTRA'GALUS. (Αςραγαλος, a cockle, or die; because it is shaped like the die used in antient games.) 1. The name of a bone of the *tarsus*, upon which the tibia moves. Ancle-bone: also called the sling-bone, or first bone of the foot. *Ballistæ os: aristrios: talus: quatrio: tetroros: cavicula: cavilla: diabebos: peza.* It is placed posteriorly and superiorly in the tarsus, and is formed of two parts, one large, which is called its body, the other small, like a process. The part where these two unite is termed the neck.

2. The name of a genus of plants in the

Linnæan system. Class, *Diadelphia.* Order, *Decandria.* Milk-vetch.

Astra′galus excapus. Stemless milk-vetch. The root of this plant, *Astragalus acaulis excapus; leguminibus lunatis; foliis villosis* of Linnæus, is said to cure confirmed syphilis, especially when in the form of nodes and nocturnal pains.

Astra′galus tragaca′ntha. The former systematic name for the plant which affords the gum tragacanth. See *Astragalus verus.*

Astra′galus ve′rus. Goat's thorn. Milk-vetch. *Spina hirci. Astragalus aculeatus.* We are indebted to a French traveller of the name of Olivier for the discovery that the gum tragacanth of commerce, is the produce of a species of astragalus not before known. He describes it under the name of *astragalus verus*, being different both from A. tragacantha of Linnæus, and from the A. gummifera of Labillardiere. It grows in the North of Persia. Gum tragacanth, or gum dragant, (which is forced from this plant by the intensity of the solar rays, is concreted into irregular lumps or vermicular pieces, bent into a variety of shapes, and larger or smaller proportions, according to the size of the wound from which it issues,) differs from all other known gums in imparting to a very large quantity of water a thick and glutinous consistence. The demulcent qualities of this gum are to be considered as similar to those of gum arabic. It is seldom given alone, but frequently in combination with more powerful medicines, especially in the form of troches, for which it is peculiarly well adapted: it gives name to an officinal compound powder, and was an ingredient in the compound powder of cerusse.

Astra′ntia vulga′ris. (From *astrum*, a star; so called from the star-like shape of its flowers.) *Astrantia nigra.* The herb sanicle masterwort. A rustic purge.

A′strape. (From *αςραπτω*, to corruscate.) Lightning. Galen reckons it among the remote causes of epilepsy.

Astri′cta. (From *astringo*, to bind.) When applied to the belly, it signifies costiveness; thus, alvus astrieta.

ASTRI′NGENTS. (From *astringo*, to constringe.) Remedies which, when applied to the body, render the solids denser and firmer, by contracting their fibres, independently of their living, or muscular power. They thus serve to diminish excessive discharges; and by causing greater compression of the nervous fibrillæ, may lessen morbid sensibility or irritability. Hence they may tend indirectly to restore the strength, when impaired by these causes. The chief articles of this class are the acids, alum, lime-water, chalk, certain preparations of copper, zinc, iron, and lead; with galls and several other vegetable substances which owe their astringency principally to tannin.

ASTRONO′MIA. (From *αςρον*, a star, and *νομος*, a law.) Astronomy, or the knowledge of the heavenly bodies. Hippocrates ranks this and astrology among the necessary studies of a physician.

ASTRUC, John, a learned physician, born in France, 1684. He studied and took his degrees at Montpelier, and became afterwards a professor there. In 1729, he was appointed physician to the king of Poland, but soon returned to his native country, was made consulting physician to the French king, and professor of medicine at Paris, where he attained great celebrity. He was author of numerous medical and philosophical works, but especially one "on Venereal Diseases," which deservedly became extremely popular, and was translated into various modern languages. He lived to the advanced age of 82.

A′suar. Indian myrobalans, or purging nut.

A′sugar. Ærugo æris, or verdigrise.

Asu′oli. Fuligo, or soot; an antispasmodic.

A′tac. Nitre.

Ata′xia. (From *α*, neg. and *τασσω*, to order.) Want of regularity in the symptoms of a disease, or of the functions of an animal body.

Ata′xir. (Arab.) A tenesmus: a disease of the eyes.

Ata′xmir. (Arab.) Removal of preternatural hairs growing under the natural ones on the eye-lids.

A′tebras. A chemical subliming vessel.

Ate′cnia. (From *α*, neg. and *τικτω*, to bring forth.) Venereal impotency: inability to procreate children.

ATHAMANTA. (*Athamanta, æ*, fœm. So named from Athamas in Thessaly.) The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.* Two species are used in medicine.

Athama′nta crete′nsis. The systematic name for the *daucus creticus* of the pharmacopœias. *Myrrhus annua.* Candy carrot. The seeds of this plant, *Athamanta: foliolis linearibus planis, hirsutis; petalis bipartitis; seminibus oblongis, hirsutis*, of Linnæus, are brought from the isle of Candy; they have an aromatic smell, and a slightly biting taste; and are occasionally employed as carminatives and diuretics in diseases of the primæ viæ and urinary passages.

Athama′nta oreoseli′num. The systematic name for the officinal *oreoselinum.* Black mountain parsley. The root and seed of this plant, *Athamanta: foliolis divaricatis* of Linnæus, as well as the whole herb, were formerly used medicinally. Though formerly in so high estimation as to obtain the epithet of *polychresta*, this plant is seldom used in the practice of the present day. An extract and tincture prepared from the root were said to be attenuant, aperient, deobstruent, and lithontriptic. The oil obtained by distillation from the seed was esteemed to allay the toothach; and the whole was recommended as an antiscorbutic and corroborant.

Athana′sia. (From α, priv. and ϑανατος, death; so called because its flowers do not wither easily.) The immortal plant. A name given to tansy; because when stuffed up the nose of a dead corpse, it is said to prevent putrefaction. See *Tanacetum*. It means also immortality. The name of an antidote of Galen, and another of Oribasius: it is the name also of a collyrium described by Aëtius, and of many other compositions.

Atha′nor. (Arab.) A chemical digesting furnace.

A′thara. (From αθηρ, corn.) A panada, or pap for children, made of bruised corn.

Athena. A plaster in much repute among the antients.

Athenato′rium. A thick glass cover formerly used for chemical purposes.

Athenio′nis catapo′tium. The name of a pill in Celsus's writings.

Atheni′ppon. *Athenippum. Diasmyrnes.* The name of a collyrium.

ATHERO′MA. (Αθηρωμα, pulse, pap.) An encysted tumour that contains a soft substance of the consistence of a poultice.

Atho′nor. (Arab.) A chemical furnace.

Athy′mia. (From α, neg. and ϑυμος, courage.) Pusillanimity. Despondence synonymous with melancholia.

Ati′ncar. (Arab.) Borax.

A′TLAS. (From ατλαω, to sustain, because it sustains the head; or from the fable of Atlas, who was supposed to support the world upon his shoulders.) The name of the first cervical vertebra. This vertebra differs very much from the others. See *Vertebræ*. It has no spinous process which would prevent the neck from being bent backwards, but in its place it has a small eminence. The great foramen of this is much larger than that of any other vertebra. Its body, which is small and thin, is nevertheless firm and hard. It is somewhat like a ring, and is distinguished into its *great arch*, which serves in the place of its body, and its *small posterior arch*. The atlas is joined superiorly to the head by ginglymus; and inferiorly, to the second cervical vertebra, by means of the inferior oblique processes and the odontoid process by trochoides.

A′TMOSPHERE. (From ατμος, vapour, and σφαιρα, a globe.) The elastic invisible fluid which surrounds the earth to an unknown height and incloses it on all sides.

Neither the properties nor the composition of the atmosphere, seem to have occupied much the attention of the antients.

Aristotle considered it as one of the four elements, situated between the regions of *water* and *fire*, and mingled with two *exhalations*, the *dry* and the *moist*: the first of which occasioned thunder, lightning, and wind; while the second produced rain, snow, and hail.

The opinions of the antients were vague conjectures, until the matter was explained by the sagacity of Hales, and of those philosophers who followed his career.

Boyle proved beyond a doubt, that the atmosphere contained two distinct substances: —

1. An elastic fluid distinguished by the name of *air*.
2. Water in a state of vapour.

Besides these two bodies it was supposed that the atmosphere contained a great variety of other substances which were continually mixing with it from the earth, and which often altered its properties and rendered it noxious or fatal. Since the discovery of carbonic acid gas by Dr. Black, it has been ascertained that this elastic fluid always constitutes a part of the atmosphere.

The constituent parts of the atmosphere, therefore, are: —

1. Air.
2. Water.
3. Carbonic acid gas.
4. Unknown bodies.

For the properties, composition, and account of the first, see *Air*.

2. *Water.* — That the atmosphere contains water, has been always known. The rain and dew which so often precipitate from it, the clouds and fogs, with which it is often obscured, and which deposit moisture on all bodies exposed to them, have demonstrated its existence in every age. Even when the atmosphere is perfectly transparent, water may be extracted from it in abundance by certain substances. Thus if concentrated sulphuric acid be exposed to air, it gradually attracts so much moisture, that its weight is increased more than three times: it is converted into diluted acid, from which the water may be separated by distillation. Substances which have the property of abstracting water from the atmosphere, have received the epithet of *hygroscopic*, because they point out the presence of that water. Sulphuric acid, the fixed alkalies, muriate of lime, nitrate of lime, and in general all deliquescent salts, possess this property. The greater number of animal and vegetable bodies likewise possess it. Many of them take water from moist air, but give it out again to the air when dry. These bodies augment in bulk when they receive moisture, and diminish again when they part with it. Hence some of them have been employed as *hygrometers* or measures of the quantity of moisture contained in the air around them. This they do by means of the increase or diminution of their length, occasioned by the addition or abstraction of moisture. This change of length is precisely marked by means of an index. The most ingenious and accurate hygrometers are those of Saussure and Deluc. In the first, the substance employed to mark the moisture is a human hair, which by its contractions and dilatations is made

to turn round an index. In the second, instead of a hair, a very fine thin slip of whalebone is employed. The scale is divided into 100°. The beginning of the scale indicates extreme dryness, the end of it indicates extreme moisture. It is graduated by placing it first in air made as dry as possible by means of salts, and afterwards in air saturated with moisture. This gives the extremes of the scale, and the interval between them is divided into 100 equal parts.

The water, which constitutes a component part of the atmosphere, appears to be in the state of vapour, and chemically combined with air in the same manner as one gas is combined with another. As the quantity of the water contained in the atmosphere varies considerably, it is impossible to ascertain its amount with any degree of accuracy.

3. *Carbonic acid gas.*—The existence of carbonic gas as a constituent part of the atmosphere, was observed by Dr. Black immediately after he had ascertained the nature of that peculiar fluid. If we expose a pure alkali or alkaline earth to the atmosphere, it is gradually converted into a carbonate by the absorption of carbonic acid gas. This fact which had been long known, rendered the inference that carbonic acid gas existed in the atmosphere unavoidable, as soon as the difference between a pure alkali and its carbonate had been ascertained to depend upon that acid. Not only alkalies and alkaline earths absorb carbonic acid when exposed to the air, but several of the metallic oxides also.

Carbonic acid gas not only forms a constituent part of the atmosphere near the surface of the earth, but at the greatest heights which the industry of man has been able to penetrate. Saussure found it at the top of Mount Blanc, the highest point of the old continent; a point covered with eternal snow, and not exposed to the influence of vegetables or animals. Limewater diluted with its own weight of distilled water, formed a pellicle on its surface after an hour and three-quarters exposure to the open air on that mountain; and slips of paper moistened with pure potash, acquired the property of effervescing with acids after being exposed an hour and a half in the same place. This was at a height no less than 15,668 feet above the level of the sea. Humboldt has more lately ascertained the existence of this gas in air, brought by Mr. Garnerin from a height not less than 4280 feet above the surface of the earth, to which height he had risen in an air-balloon. This fact is a sufficient proof that the presence of carbonic acid in air does not depend upon the vicinity of the earth.

Now, as carbonic acid gas is considerably heavier than air, it could not rise to great heights in the atmosphere unless it entered into combination with the air. We are warranted, therefore, to conclude, that carbonic acid is not merely mechanically mixed, but that it is chemically combined with the other constituent parts of the atmosphere. It is to the affinity which exists between carbonic acid and air that we are to ascribe the rapidity with which it disperses itself through the atmosphere, notwithstanding its great specific gravity. Fontana mixed 20,000 cubic inches of carbonic acid gas with the air of a close room, and yet half an hour after he could not discover the traces of carbonic acid in that air. Water impregnated with carbonic acid, when exposed to the air, very soon loses the whole of the combined gas. And when a phial full of carbonic acid gas is left uncorked, the gas, as Bergman first ascertained, very soon disappears, and the phial is found filled with common air.

The difficulty of separating this gas from air has hitherto prevented the possibility of determining with accuracy the relative quantity of it in a given bulk of air; but from the experiments which have been made, we may conclude with some degree of confidence, that it is not very different from 0.01. From the experiments of Humboldt, it appears to vary from 0.005 to 0.01. This variation will by no means appear improbable, if we consider that immense quantities of carbonic acid gas must be constantly mixing with the atmosphere, as it is formed by the respiration of animals, by combustion, and several other processes which are going on continually. The quantity, indeed, which is daily formed by these processes is so great, that at first sight it appears astonishing that it does not increase rapidly. The consequence of such an increase would be fatal, as air containing 0.1 of carbonic acid extinguishes light, and is destructive to animals. But there is reason to conclude, that this gas is decomposed by vegetables as rapidly as it forms.

4. *Bodies found in the atmosphere.*—From what has been advanced, it appears that the atmosphere consists chiefly of three distinct elastic fluids united together by chemical affinity; namely, air, vapour, and carbonic acid gas; differing in their proportions at different times and in different places; the average proportion of each is

98.6	air
1.0	carbonic acid
0.4	water
100.0	

But besides these bodies, which may be considered as the constituent parts of the atmosphere, the existence of several other bodies has been suspected in it. It is not meant in this place to include among those bodies electric matter, or the substance of clouds and fogs, and those other bodies which are considered as the active agents in the phenomena of meteorology, but merely those foreign bodies which have been occasionally found or suspected in air. Concerning these bodies, however, very little satisfactory is known at present, as we are not in possession of instruments sufficiently delicate to ascertain their presence. We can indeed detect several of them actually mixing with air, but what becomes of them afterwards we are unable to say.

1. Hydrogen gas is said to have been found in air situated near the crater of volcanoes, and it is very possible that it may exist always in a very small proportion in the atmosphere; but this cannot be ascertained till some method of detecting the presence of hydrogen combined with a great proportion of air be discovered.

2. Carburetted hydrogen gas is often emitted by marshes in considerable quantities during hot weather. But its presence has never been detected in air; so that in all probability it is again decomposed by some unknown process.

3. Oxygen gas is emitted abundantly by plants during the day. There is some reason to conclude that this is in consequence of the property which plants have of absorbing and decomposing carbonic acid gas. Now as this carbonic acid gas is formed at the expense of the oxygen of the atmosphere, as this oxygen is again restored to the air by the decomposition of the acid, and as the nature of atmospheric air remains unaltered, it is clear that there must be an equilibrium between these two processes; that is to say, all the carbonic acid formed by combustion must be again decomposed, and all the oxygen abstracted must be again restored. The oxygen gas which is thus continually returning to the air, by combining with it makes its component parts always to continue in the same ratio.

4. The smoke and other bodies which are continually carried into the air by evaporation, &c. are probably soon deposited again, and cannot therefore be considered with propriety as forming parts of the atmosphere. But there is another set of bodies, which are occasionally combined with air, and which, on account of the powerful action which they produce on the human body, have attracted a great deal of attention. These are known by the name of *contagions*.

That there is a difference between the atmosphere in different places, as far as respects its effects upon the human body, has been considered as an established point in all ages. Hence some places have been celebrated as healthy, and others avoided as pernicious, to the human constitution. It is well known that in pits and mines the air is often in such a state as to suffocate almost instantaneously those who attempt to breathe it. Some places are frequented by peculiar diseases. It is known that those who are much in the apartments of persons ill of certain maladies, are extremely apt to catch the infection; and in prisons and other places, where crowds of people are confined together, when diseases once commence, they are wont to make dreadful havoc. In all these cases, it has been supposed that a certain noxious matter is dissolved by the air, and that it is the action of this matter which produces the mischief.

This noxious matter is in many cases readily distinguished by the peculiarly disagreeable smell which it communicates to the air. No doubt this matter differs according to the diseases which it communicates, and the substance from which it has originated. Morveau lately attempted to ascertain its nature; but he soon found the chemical tests hitherto discovered altogether insufficient for that purpose. He has put it beyond a doubt, however, that this contagious matter is of a compound nature, and that it is destroyed altogether by certain agents. He exposed infected air to the action of various bodies, and he judged of the result by the effect which these bodies had in destroying the fetid smell of the air. The following is the result of his experiments.

1. Odorous bodies, such as benzoin, aromatic plants, &c. have no effect whatever. 2. Neither have the solutions of myrrh, benzoin, &c. in alkohol, though agitated in infected air. 3. Pyroligneous acid is equally inert. 4. Gunpowder, when fired in infected air, displaces a portion of it; but what remains, still retains its fetid odour. 5. Sulphuric acid has no effect; sulphurous acid weakens the odour, but does not destroy it. Distilled vinegar diminishes the odour, but its action is slow and incomplete. 7. Strong acetic acid acts instantly, and destroys the fetid odour of infected air completely. 8. The fumes of nitric acid, first employed by Dr. Carmichael Smith, are equally efficacious. 9. Muriatic acid gas, first pointed out as a proper agent by Morveau himself, is equally effectual. 10. But the most powerful agent is oxymuriatic acid gas, first proposed by Mr. Cruickshanks, and now employed with the greatest success in the British navy and military hospitals.

Thus there are four substances which have the property of destroying contagious matter, and of purifying the air; but acetic acid cannot easily be obtained in sufficient quantity, and in a state of sufficient concentration to be employed with advantage. Nitric acid is attended with inconvenience, because it is almost always contaminated with nitrous gas. Muriatic acid and oxymuriatic acid are not attended with these inconveniences; the last deserves the preference, because it acts with greater energy and rapidity. All that is necessary is to mix together two parts of salt with one part of the black oxide of manganese, to place the mixture in an open vessel in the infected chamber, and to pour upon it two parts of sulphuric acid. The fumes of oxymuriatic acid are immediately exhaled, fill the chamber, and destroy the contagion.

Ato′chia. (From α, neg. and τοκος, offspring; from τικτω, to bring forth.) Inability to bring forth children. Difficult labour.

ATONIC. Relaxed, having a diminution of strength.

A′TONY. (From α, neg. and τεινω, to extend.) A defect of muscular power, weakness, and debility.

Atrabilia′riæ ca′psulæ. See *Renal glands.*

Atrabi′lis. Black bile or melancholy.

Atrache′lus. (From α, priv. and τραχηλος, the neck.) Short-necked.

Atrage′ne. The *Clematis vitalba* of Linnæus: which see.

Atrame′ntum suto′rium. A name of green vitriol.

Atra′sia. (From α, neg. and τιτραω, to perforate.) *Atresia.* Imperforation. A disease where the anus or genitals have not their usual orifice.

Atreta′rum. (From α, neg. and τραω, to perforate.) A suppression of urine from the menses being retained in the vagina.

A′trices. (From α, priv. and θριξ, hair.) Small tubercles about the anus upon which hairs will not grow. *Vaselius.*

A′trici. Small sinuses in the rectum, which do not reach so far up as to perforate into its cavity.

A′TRIPLEX. (*Atriplex-icis*, f. said to be named from its dark colour, whence it was called *atrum olus.*) The name of a genus of plants in the Linnæan system. Class, *Polygamia.* Order, *Monœcia.* Orach.

A′triplex fœ′tida. See *Chenopodium vulvaria.*

A′triplex horte′nsis. The systematic name for the *atriplex sativa* of the pharmacopœias. The herb and seed of this plant, *Atriplex caule erecto herbaceo, foliis triangularibus,* of Linnæus, have been exhibited medicinally as antiscorbutics, but the practice of the present day appears to have totally rejected them.

A′triplex sati′va. See *Atriplex hortensis.*

A′TROPA. (From Ατροπος, the goddess of Destiny; so called from its fatal effects.) The deadly night-shade. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

A′tropa bellado′nna. The systematic name for the *belladonna* of the pharmacopœias. *Solanum melonocerasus. Solanum lethale.* Deadly night-shade or dwale. *Atropa: caule herbaceo; foliis ovatis integris,* of Linnæus. This plant has been long known as a strong poison of the narcotic kind, and the berries have furnished many instances of their fatal effects, particularly upon children that have been tempted to eat them. The leaves were first used internally, to discuss scirrhous and cancerous tumours; and from the good effects attending their use, physicians were induced to employ them internally, for the same disorders; and there are a considerable number of well-authenticated facts, which prove them a very serviceable and important remedy. The dose, at first, should be small; and gradually and cautiously increased. Five grains are considered a powerful dose, and apt to produce dimness of sight, vertigo, &c.

A′tropa mandra′gora. The systematic name for the plant which affords the *radix mandragoræ* of the pharmacopœias. Mandrake. The boiled root is employed in the form of poultice, to discuss indolent tumours.

ATRO′PHIA. (From α, neg. and τρεφω, to nourish.) *Atrophia. Marasmus.* Atrophy. Nervous consumption. This disease is marked by a gradual wasting of the body, unaccompanied either by a difficulty of breathing, cough, or any evident fever, but usually attended with a loss of appetite and impaired digestion. It is arranged by Cullen in the class *cachexiæ*, and order *marcores.* There are four species:—

1. When it takes place from too copious evacuations, it is termed *atrophia inanitorum;* by others called *tabes nutricum;—sudatoria;—à sanguifluxu,* &c.

2. When from famine, *atrophia famelicorum.*

3. When from corrupted nutriment, *atrophia cacochymica.*

4. And when from an interruption in the digestive organs, *atrophia debilium.*

The atrophy of children is called *paidatropia.* The causes which commonly give rise to atrophy, are a poor diet, unwholesome air, excess in venery, fluor albus, severe evacuations, continuing to give suck too long, a free use of spirituous liquors, mental uneasiness, and worms; but it frequently comes on without any evident cause. Along with the loss of appetite and impaired digestion, there is a diminution of strength, the face is pale and bloated, the natural heat of the body is somewhat diminished, and the lower extremities are œdematous. Atrophy, arise from whatever cause it may, is usually very difficult to cure, and not unfrequently terminates in dropsy.

A′trophy. See *Atrophia.*

ATTE′NUANTS. (*Attenuantia,* sc. *medicamenta;* from *attenuo,* to make thin.) Diluents. Those substances are so termed, which possess a power of imparting to the blood a more thin and more fluid consistence than it had previous to their exhibition; such are, *aqua, serum lactis,* &c.

ATTO′LLENS AU′REM. (*Attollens;* from *attollo,* to lift up.) *Attollens auriculæ* of Albinus and Douglas: *Superior auris* of Winslow, and *Attollens auriculam* of Cowper. A common muscle of the ear, which arises, thin, broad, and tendinous, from the tendon of the occipito-frontalis, from which it is almost inseparable, where it covers the aponeurosis of the temporal muscle; and is inserted into the upper part of the ear, opposite to the antihelix. Its use is to draw the ear upwards, and to make the parts into which it is inserted, tense.

Atto'llens o'culi. One of the recti-muscles which lies upon the upper part of the globe and pulls up the eye.

Atto'nitus mo'rbus. (From *attono*, to surprise; so called because the person falls down suddenly.) *Attonitus stupor.* The apoplexy and epilepsy.

ATTRACTION. (From *attraho*, to attract.) Affinity. The terms attraction, or affinity, and repulsion, in the language of modern philosophers, are employed merely as the expression of the general facts, that the masses or particles of matter have a tendency to approach and unite to, or to recede from one another under certain circumstances.

All bodies have a tendency or power to attract each other more or less, and it is this power which is called attraction.

Attraction is mutual, it extends to indefinite distances. All bodies whatever, as well as their component elementary particles, are endued with it. It is not annihilated, at how great a distance soever we suppose them to be placed from each other; neither does it disappear though they be arranged ever so near each other.

The nature of this reciprocal attraction, or at least the cause which produces it, is altogether unknown to us. Whether it be inherent in all matter, or whether it be the consequence of some other agent, are questions beyond the reach of human understanding; but its existence is nevertheless certain.

Proofs of attraction.

That the power of attraction really exists, is obvious from the slightest view of the phenomena of nature. It is proved with mathematical certainty, that the celestial bodies which constitute the solar system, are urged towards each other by a force which preserves them in their orbits. It is further proved beyond any doubt, that this planetary attraction is possessed not only by the heavenly bodies as wholes, but that it also extends to the smaller particles of which they are formed, as may be evinced by means of the following experiments.

First. — If we place two or more globules of mercury on a dry glass or earthen plate, and push them gently towards each other, the globules will attract each other, and form one mass or sphere greater in bulk, but precisely the same in nature.

Secondly. — If a plate of clean glass, perfectly dry, be laid on a large globule of mercury, the globule, notwithstanding the pressure applied to it, continues to preserve its spherical form: if we gradually charge the plate with weights carefully, the globule will be flattened, and become thinner and thinner; but if we again remove the weights from the plate, the mercury will instantly recover its globular figure, and push up the glass before it.

In both these experiments, we see that there exists an attraction between the particles of mercury; in the first, the globules which are in contact with the plate of glass leave this substance completely, they attract each other, and form a sphere greater in bulk. A mere inert fluid would in any case retain the figure it once possessed. It could not be endued with a globular form, unless a real reciprocal attraction among its particles took place, which in the latter experiment is still more striking, for it there is not only superior to gravitation, but actually overcomes an external force.

Thirdly. — If a glass tube of a fine bore be immersed in water, contained in any vessel, the fluid will ascend to a certain height within the tube above its level, and its elevation in several tubes of different sizes, will be reciprocally as the diameter of their bores.

This kind of attraction which takes place as well *in vacuo* as in the open air, has been called capillary attraction. It is this attraction which causes water to rise in sponge, cloth, sugar, sand, &c. for all these substances may be considered as fine tubes in which the fluid ascends.

Remark. — The ascension of fluids in glass tubes of a fine bore, succeeds best when the inside of the tube has been previously moistened, which may conveniently be done by blowing through it with the mouth. And if the water be coloured with a little red or black ink, its ascension will be more obvious, particularly if the tube be held against a sheet of white paper.

Fourthly. — If two plates of glass, previously wetted, be made to meet on one side, and be kept open at the other, at a small distance, by the interposition of a shilling, or any other thin substance, and then immersed in water, the fluid will ascend between the two plates unequally. Its upper surface will form a curve, in which the heights of the several points above the surface of the fluid will be to one another reciprocally, as their perpendicular distance from the line in which the plates meet. The ratio of this attraction is therefore as the squares of the increments with which the plates open.

Here then we have two other instances that an attraction prevails among the particles of bodies. For in both cases, part of the fluid has left the contiguous mass, contrary to the laws of gravitation. It is drawn up as it were, or attracted by the tube, or plate of glass.

Fifthly. — If we immerse a piece of tin, lead, bismuth, silver, or gold, in mercury, and draw it out again immediately, the mercury will attract the metal, and the latter will carry with it a portion of the former, which will stick to it so obstinately as to be inseparable by mere friction.

There exists therefore an attraction between the different metals brought in contact with each other.

Sixthly. — If a small stick be dipt in water or any other fluid, and drawn out again, a drop will be found hanging at the end of it of a spherical form. The drop is spherical, because each particle of the fluid exerts an equal force in every direction, drawing other particles towards it on every side, as far as its power extends.

Thus the very formation of drops obviously demonstrates that there must exist a cause which produces that effect. This cannot be gravity, for, agreeably to experience, that is rather an obstacle to the formation of drops, since by the weight of the particles, large globules resting on solid bodies are flattened, and their regular spherical form prevented.

To explain this phenomenon, there remains only the power of attraction, acting between the particles of the liquid body; for if it is supposed that the particles of a substance reciprocally attract each other with equal force, and their aptitude for being moved upon one another be great enough to overcome any impediment to their motion, it follows by the principles of mechanics, that the equilibrium of the attractive forces can only take place when the mass has received a globular form.

Hence it is, that all liquid bodies assume a spherical figure, when suffered to fall through the air, or form drops.

Division of attraction.

Though we are unable to discover the cause of the mutual attraction, experience has proved to us, that this agency follows certain conditions or laws; for similar phenomena always present themselves, whenever the circumstances of experiment are the same.

Observation has taught us, that attraction takes place between bodies of the same kind, and bodies of a different kind. The first is called *attraction of aggregation*, also *corpuscular attraction; molecular attraction;* and *attraction of cohesion*, or *the cohesive power.*

The latter is termed *chemical attraction, chemical affinity*, or *affinity of composition.*

ATTRACTION OF AGGREGATION.

Corpuscular attraction, or attraction of cohesion or aggregation, is that power by means of which the similar particles of bodies attract each other, and become united into one mass, without changing in the least the chemical properties they possessed before their union. The bodies may be in a solid, fluid, or aëriform state.

This attraction is different in different bodies. It is always in an inverse ratio to the power of repulsion, or the quantity of caloric interposed between the particles of the acting bodies.

It becomes obvious from this, that the agency of attraction of aggregation consists in a mere successive and constant accumulation of similar particles into one mass; and that it produces adherence of surface, or apparent contact in the ratio of the surfaces.

This force is inherent in all the particles of all bodies (caloric and light, perhaps, excepted); we never find the particles of bodies in a detached state, but constantly in masses of greater or smaller magnitude, made up of an indefinite number of particles united together by virtue of the force of cohesion.

The simplest case of the exertion of the attraction of aggregation is that, where two bodies placed in mutual contact with each other form a direct union, without changing their chemical properties: thus if different portions of sulphur be melted together, they form an uniform mass or whole, the particles of which are held together by virtue of the power of attraction of aggregation, but the properties of the body are not altered.

The same effect takes place when pieces of the same metal, or particles of resin, wax, &c. are united in a similar manner.

The force of this attraction in solid bodies may be measured by the weight necessary to overcome it. Thus if a rod of metal, glass, wood, &c. be suspended in a perpendicular direction, and weights be attached to its lower extremity, till the rod is broken by them, the weight attached to the rod just before it broke is the measure of the cohesive force of the rod.

Laws of attraction of aggregation.

1. The agency of attraction of aggregation is exerted only at insensible distances; its force increases as the distance of the bodies presented to each other decreases, and as the surfaces of apparent contact are larger: thus, if we take two sections of a leaden ball, having each a flat and smooth surface, and press them forcibly together, they will cohere, and a considerable effort is necessary to force them asunder: so also two plates of glass wetted with a little water to fill up their inequalities, when laid together, will cohere; and two pieces of marble having each a flat, smooth, and well-polished surface, when moistened and slipt upon each other with a gentle pressure, will unite, and a considerable force is required to separate them. But if the two substances placed together be not sufficiently smooth or polished, it will be in vain to try to cause them to adhere together; for this reason, that the particles touch each other only in a few points, whereas, on the contrary, the

particles of the former flat and smooth surfaces touch each other in many points. It has been noticed, that a silk-worm's thread can be interposed, but not two.

The pressure of the atmosphere has no influence on these experiments, for they succeed equally well *in vacuo* as in the open air.

It is on this account that carpenters, when they intend to glue pieces of wood together, plane the surfaces perfectly smooth before they apply the glue: and that the surfaces of metals are scraped clean before they are soldered, &c.

Hence the attraction of aggregation always vanishes whenever the distance is measurable, and becomes exceedingly great whenever the distance is exceedingly diminished; but the particular rate which this power follows, is still unknown, as we have no method of measuring either the distance at which it acts, or its relative intensity.

2. Attraction of aggregation acts differently in different bodies; according to the degree of force with which it acts between the particles of matter, the bodies appear under different forms.

It is on this account that rock-crystal, flint, diamond, and various other precious stones are extremely hard, for the attraction of aggregation unites the particles of these bodies with a great degree of force. Hence a considerable mechanical effort is necessary to disunite them.

In blocks of marble, chalk, lime-stone, &c. the particles are held together with a force considerably less. In these bodies it prevents all relative motion among the particles themselves, and hence the motion of one particle is followed by the motion of the whole mass; or if that is impossible, the cohesion is destroyed altogether, and the piece breaks.

The integrant parts of wax, tallow, suet, or lard, may be made to change their situations, with a less degree of force than the former.

In these substances, the motion of one particle of the body is not necessarily followed by that of all the rest, neither does that motion destroy the cohesion, nor break them.

The particles of water, spirit, and ether, move or slide over each other very readily; hence their resistance is considerably less.

And lastly, vapours, the air of the atmosphere, and all the gases, yield to the slightest possible impulse.

3. Attraction of aggregation may be annihilated by every effort which tends to separate the particles of bodies, if powerful enough.

It need hardly be mentioned that all mechanical forces, such as grinding, cutting, filling, rasping, pounding, breaking, &c. are of this nature.

In all these cases the force applied must be more than equal to the force of the attraction; and, as it was stated before, that the attraction of aggregation acts with different degrees of force between the particles of different bodies, so different degrees of force are necessary to destroy that attraction in different bodies: and hence it is that chalk is more easily reduced to powder than flint; wood is easier broken than lead; lead easier than iron, &c.

CHEMICAL AFFINITY.

Chemical affinity, or affinity of composition, is that power, by means of which the particles of compound bodies attract each other so intimately as to produce an uniform whole, totally inseparable by mechanical efforts, and the characteristic properties of the compound are often different, and sometimes contrary to those of its constituent parts.

It is obvious from this, that the particles of those bodies which are united by virtue of chemical affinity, form not a mere aggregate, but an entire new body, which can only be altered by the action of another chemical power.

In considering this kind of affinity, it will be necessary to state; — In what manner it takes place between the particles of different bodies; — In what proportion they are capable of combining; — Under what conditions; — With what degree of force they unite; — And what takes place when a variety of different substances are made to act upon each other at the same time, under certain circumstances and in different proportions.

Hence chemical affinity is of greater importance than affinity of aggregation, for it takes place in all the complex operations of chemistry.

Instances of chemical affinity.

To prove that chemical affinity acts differently from attraction of aggregation; that it takes place between the ultimate constituent parts of bodies; and that it produces substances possessing properties, frequently very different, and sometimes contrary to those of the constituent parts, the following experiments may serve.

1. Put into a crucible placed in a coal fire, equal parts by weight of sulphur and mercury; stir the two substances together for a few minutes, and when the sulphur is melted, pour the contents out on a marble slab, or a piece of glass previously warmed and greased.

The substance obtained by this means is a *sulphuret of mercury*, in which the mercury and sulphur are united by virtue of chemical affinity; for the compound has neither the colour, the splendour, the inflammability, the volatility, nor the specific gravity of either of its constituent parts; nor can the sulphur and mercury be separated by mechanical means; they are therefore chemically united.

2. If we melt together two very malleable and ductile metals, for instance, tin and

iron, in equal quantities, the compound produced will have totally lost the properties which its constituent parts possessed before their union, for the alloy formed will be a brittle metal which may easily be broken by the blow of a hammer.

3. Put two or three teaspoonfuls of an aqueous infusion of red cabbage or syrup of violets, into a wine-glass of water, mix it well, and put half the mixture into another glass. By adding a few drops of sulphuric acid to one of the glasses and stirring it, the blue will be changed to a crimson; and by adding an alkali, for instance potash, to the other glass, the blue fluid will be changed into a green.

If we drop carefully down the sides of the glass into the green obtained in this experiment, a few drops of sulphuric acid, crimson will be perceived at the bottom, purple in the middle, and green at the top. On adding a little alkali to the other glass, containing the crimson, these colours will appear in an inverted order.

4. When equal parts of muriate of ammonia and slacked lime, both substances destitute of odour, are intimately blended in a stone mortar, a very pungent gas (ammonia) becomes evolved.

5. Water impregnated with ammonia and concentrated muriatic acid, both fluids of a strong odour, when mixed together in proper proportions, instantly lose their odour, and form a fluid void of smell, (a solution of muriate of ammonia.)

6. Into a saturated solution of muriate of lime, let fall gradually concentrated sulphuric acid, a quantity of pungent vapour will become disengaged, (muriatic acid gas,) and from the two fluids will thus be produced an almost solid compound, called sulphate of lime.

7. Let equal parts of fresh crystallized acetate of lead and acidulous sulphate of alumine and potash, (alum) be rubbed together intimately in a stone mortar, the saline mixture will soon become soft, and lastly fluid.

A like effect is produced by treating in a similar manner equal parts of crystallized nitrate of ammonia and sulphate of soda.

A solid alloy of mercury and bismuth, and another composed of lead and mercury, on being triturated together, instantly become fluid.

It is obvious from this, that when chemical combination takes place, the compound which is formed does not possess properties merely intermediate between those of its component parts, but has acquired others more or less new. This however does not hold good in all cases. There are various combinations in which the properties of bodies are only slightly altered: and in these cases the union does not appear so intimate, as where the change is greater.

Laws of chemical affinity.

Observation has shown that affinity of composition offers certain invariable phenomena, which being founded on a great number of facts are regarded by chemists as laws, and may be reduced under the following heads.

Law I. — Chemical affinity can exert its action between a number of bodies, simple or compound, and unite them chemically into one whole.

Law II. — The efficacy of chemical affinity is in an inverse ratio to that of attraction of aggregation.

Law III. — The agency of chemical affinity is influenced by temperature; its action is either accelerated, retarded, prevented, or rendered efficacious.

Law IV. — Chemical affinity is generally accompanied by a change of temperature at the instant of its action.

Law V. — The chemical affinity existing between two or more bodies may be dormant, until it is called into action by the interposition of another body which frequently exerts no energy upon any of them in a separate state.

Law VI. — The ratio of the energy of chemical affinity acting between various bodies, is different in different substances.

Law VII. — The agency of chemical affinity is either limited, or unlimited in certain bodies; in other words, chemical affinity is capable of uniting bodies in definite, or in indefinite proportions.

Law VIII. — The energy of the chemical affinity of different bodies is modified in proportion to the ponderable quantities of the bodies placed within the sphere of action.

Such are the leading laws which regulate chemical affinity; they may be demonstrated by experiments.

I. Chemical affinity can exert its action between a number of bodies, simple or compound, and unite them chemically into one whole: —

There are an infinite variety of compounds, consisting of three, four, five or more simple substances in nature; and art can also effect combinations in which there are many simple bodies chemically united into one whole.

It frequently happens that various separate bodies presented to each other in a fluid, unite and form a single mass, which possesses all the characters of an homogeneous compound, and which retains these characters till its composition has been altered by chemical means.

A considerable number of triple salts are known, which consist of three different substances; for instance, the common alum of commerce consists of sulphuric acid united to alumine and potash or ammonia. The salt formerly called microcosmic salt, or phosphate of soda and ammonia, consists of phosphoric acid united to soda and ammonia, &c. When the oxygenated muriate of mercury is precipitated by the precise quantity of carbonate of soda which is requisite to effect its decomposition, the precipitate obtained contains muriatic acid, carbonic acid, and oxide of mercury in excess.

It is a well-known fact that two, three, or more metals may be fused together so as to produce compounds whose properties are widely different from those of the constituent parts.

Melt together in an iron ladle or crucible, eight parts of bismuth, five of lead, and three of tin, the fusibility of the metals will thus be altered, for the alloy melts at 212° Fahr. A spoon or any other utensil formed of this compound will therefore melt in water kept boiling.

If in a similar manner an alloy be made of lead, tin, bismuth, and mercury, their proportions being two, three, five, and one, the compound produced melts at a heat even less than that of boiling water.

A composition of lead, zinc, and bismuth, in equal parts, may be kept in fusion upon paper over a lamp.

II. The efficacy of chemical affinity is in an inverse ratio to that of corpuscular attraction: —

The cohesion of the particles of a body is owing to the mutual affinity existing between them. It is this force which must be overcome by the action of the substance which has a tendency to combine with those particles chemically. Chemical affinity therefore does not become *stronger* as the affinity of aggregation becomes *weaker*, it becomes only *more efficacious;* the absolute powers remain the same; the effect produced by that agency *increases*, because the resistance opposed to it *decreases*.

Remark.—It is from this law that it was formerly inferred that some or at least one of the bodies should be in a state of fluidity. This however is by no means necessary. It is in general true, that the weaker the attraction of aggregation is, the more easily chemical affinity takes place, as may be evinced by means of the following experiments:

Let any quantity of dry carbonate of soda and tartaric acid be mingled together, and put the mixture into a wine glass, no obvious chemical change will be produced; but if water be added, or either of the salts be previously dissolved, a violent effervescence ensues, and a chemical union is obtained.

The water added is of use merely to overcome the resistance which arises from the cohesion of the particles of the salts intended to be brought into the sphere of action, or to increase their mutual contact.

If we let fall a crystal, or lump of fluor spar, (fluate of lime,) into concentrated sulphuric acid, no sensible action will take place, both the sulphuric acid and the fluate of lime remain unaltered; but if the former be reduced to powder, and then brought into contact with the acid, a considerable action instantly takes place, the sulphuric acid unites to one of the constituent parts of the fluor spar, namely, to the lime, and its other constituent part, the fluoric acid, becomes disengaged in the state of white vapour, or fluoric acid gas.

If crystallized alum, or sulphate of soda, and acetate of lead, are brought into contact with each other, the individuality of these bodies will not be destroyed, that is to say, no chemical change will take place; but if they be intimately rubbed together in a mortar, the two solids will act upon each other and form a fluid.

It is obvious therefore that in order to facilitate chemical affinity, the attraction of aggregation must be broken; the bodies intended to be chemically united must not be presented to each other in mass, but mechanically divided, or reduced to the smallest molecules possible: hence liquids combine with more facility than solids, or even than a solid and a liquid, and in like manner vapours combine with rapidity and ease.

III. The agency of chemical affinity is influenced by temperature. Its action is either accelerated, retarded, prevented, or rendered efficacious: —

If we expose phosphorus in an open vessel to the action of the atmosphere, a chemical union will take place between the phosphorus and one of the constituent parts of the atmosphere, namely, the oxygen gas; the phosphorus will gradually (but very slowly) disappear, and become converted into a fluid called phosphorous acid.

But if we heat the vessel containing the phosphorus, the latter will take fire, and become converted into a white substance, which in a short time is changed into an acid analogous to the former.

If equal quantities of muriate of ammonia and carbonate of magnesia are mixed with six or eight parts of water, and suffered to stand for some time exposed to the ordinary temperature of the atmosphere, a mutual decomposition of the two salts will take place. For if the fluid which passes the filter, be left to evaporate spontaneously, muriate of magnesia and carbonate of ammonia will be obtained. On the contrary:

If equal quantities of muriate of magnesia and carbonate of ammonia be exposed to a temperature of 200° in about four parts of water, the products obtained are, muriate of ammonia and carbonate of magnesia.

If muriate of soda and sulphate of magnesia be mixed together in any proportion, and exposed to a temperature below *zero*, they decompose each other, and muriate of magnesia and sulphate of soda are formed, but no decomposition takes place at a temperature above 30°.

Muriate of soda and acidulous sulphate

of alumine and potash, exhibit precisely the same phenomena.

If ardent spirit and a solution of salt in water be mixed together, the compound formed is a real chemical union; but if we carefully heat the fluid, the caloric applied will be divided between the three ingredients according to their respective affinities; the union will be broken, for the ardent spirit will first become volatilised, and the union of the salt and water remain unaltered. On increasing the temperature, the water will escape in the form of vapour, and the salt will be left behind.

There are numerous cases in which an increase of temperature is essentially necessary to determine bodies to unite. If pure mercury be exposed to oxygen gas at the common temperature of the atmosphere, the corpuscular attraction subsisting between its particles is sufficient to prevent combination. But if the mercury be heated to a certain degree, the force which kept its particles united will become annihilated, and it then combines with the oxygen which is present.

Again, if the oxide of mercury thus formed be exposed to a higher degree of temperature, the union is demolished, and the quicksilver re-appears in its metallic state.

Hence it is obvious that the action of caloric favours the union of the oxygen and mercury, in consequence of the diminution of the mutual affinity of the parts of the latter: but at length, by augmenting the elastic force of the oxygen, it again breaks the union, or renders the combination impossible.

That increased temperature augments the power of chemical union, the solutions of many salts in the water afford proofs.

A larger quantity of salt is soluble in a given quantity of water at a high, than at a low temperature, and this larger quantity of salt is again separated by cooling.

IV. Chemical affinity is generally accompanied by a change of temperature at the instant of its action: —

When equal parts of concentrated sulphuric acid and ardent spirit are mingled together, the mixture in a few minutes becomes so hot as to render the vessel insupportable to the hands.

If four parts of sulphuric acid of commerce, and one part, by weight, of water, be mixed together, each at the temperature of 50°, the mixture immediately acquires a temperature of about 300°.

All the dense acids, ammonia, and ardent spirit, when mixed with water, have the property of raising its temperature remarkably: and the same is the case when alkalies are introduced into concentrated acids. On the contrary, in many instances cold is produced: —

Take one ounce and a half of muriate of ammonia, and a like quantity of nitrate of potash; reduce each of these salts separately to a powder, and blend them intimately together: having done this, mix them gradually in a glass bason, or other thin glass vessel, with four ounces of water. The result will be, that the cold produced will sink a thermometer immersed in it, to 36° Fahr. A new addition of the same quantity of salts will cool it to 14°, which therefore will freeze water in a glass tube that is immersed in it, without the use of snow or ice. If the water used in a first process be used to reduce other water and salts to the temperature of about 32°, and these be applied to the performance of a second experiment, the temperature may be lowered to 4° below 0°.

A number of experiments have lately been made to produce artificial cold by means of such freezing mixtures. The most complete set of this kind are those of Pepys, Lowitz, and Walker.

V. The chemical affinity between two or more bodies may lie dormant, until it is called into action by the interposition of another body, which frequently exerts no energy upon any of them in a separate state.

From this law originates what was formerly called disposing affinity, or that case in which two or more bodies are incapable of uniting, until the agency is called into action by the addition of a third body, which exerts no sensible affinity upon either of them. This may be proved in the following manner.

Water is a compound of hydrogen and oxygen; phosphorus is a simple body according to our present state of knowledge. If these be presented to each other, no chemical union will take place; but if we add to them an alkali, and then apply heat, the water will become decomposed; that is to say, part of the phosphorus will unite to the oxygen of the water, and form phosphoric acid, and the other part will be dissolved in the hydrogen gas and appear as phosphuretted hydrogen.

Here the alkali acts as the substance requisite to favour the mutual action, or to give the disposing affinity.

If iron and water be brought into contact with each other, no perceptible change will be produced; but if a little sulphuric acid be added to the water and iron, a violent effervescence will take place, the water will become decomposed, hydrogen gas will be evolved, and the iron become dissolved in the acid.

In this case the sulphuric acid is the condition necessary to accelerate the chemical action.

VI. The ratio of the energy of chemical affinity acting between various bodies, is different in different substances.

This is the most important law of chemical attraction. As beginners will find it rather difficult to understand what passes in this more complicated agency, they must remember, that the combination which is effected between two or more bodies by virtue of chemical affinity becomes broken whenever we present to the compound another body, which has an attraction to one of the constituent parts of the compound, superior to that attraction by which they were held together: the bodies, therefore, between which the strongest attraction prevails, combine, and the rest are disengaged, thus:—

If muriatic acid be poured either on pure barytes, or on its carbonate, the barytes will be dissolved, and the compound will be muriate of barytes, which compound is held together by the force of affinity existing between the muriatic acid and the barytes. On letting fall into this solution a few drops of sulphuric acid, an immediate change of principles takes place; the whole quantity of the muriatic acid which was combined with the barytes becomes disengaged, and the sulphuric acid unites to the barytes with a force equal to their affinity, *minus* that of the muriatic acid for the barytes.

Again, if pure silver be dissolved in pure nitric acid, part of this is decomposed to furnish oxygen, to which and the remaining acid the silver will remain united, till another body is presented to it, which has a greater force of attraction to one of the constituent parts of the compound; for instance, if mercury be added to this solution of silver, the mercury will be dissolved, and the silver becomes precipitated or disengaged. The supernatant fluid will then be a *solution of oxide of mercury in nitric acid.*

If to the before-obtained solution, a piece of sheet-lead be presented, the lead will be dissolved, and the mercury become precipitated. The fluid will then be a *solution of oxide of lead in nitric acid.*

If in this solution of lead, a thin slice of copper be suspended, the copper will be dissolved, and the lead will become disengaged. The fluid now is a *solution of oxide of copper in nitric acid.*

If in this solution of copper, a thin sheet of iron be kept immersed, the iron will be dissolved, and the copper become precipitated. The fluid now is a *solution of oxide of iron in nitric acid.*

If to this solution of iron, a piece of zinc be presented, the zinc will be dissolved, and the iron become precipitated. The solution then consists of *zinc, oxygen, and nitric acid.*

If to this solution of oxide of zinc in nitric acid, some ammonia be gradually added, the ammonia will join to the acid, and the oxide of zinc will be precipitated. The solution will then be *nitrate of ammonia.*

If to this solution of nitrate of ammonia, some lime-water be added, the ammonia will become disengaged, (and manifest itself by a pungent odour,) and the solution will be *nitrate of lime.*

If to this solution of nitrate of lime, some oxalic acid be added, the lime will be precipitated by this, and what now remains will be merely *nitric acid.*

We see from these experiments, that different bodies have different degrees of affinity for one and the same substance, which can only be learnt from observation and experiments.

VII. The agency of chemical affinity is either limited or unlimited; in other words, chemical affinity is capable of uniting bodies in definite, or in indefinite proportions:—

Experience has convinced us, that in bodies generally there are certain precise limits of combination beyond which their action cannot pass; it remains still to be ascertained how bodies can combine within these limits.

If we attend to what is known at present, we are forced to acknowledge that this law comprehends several modifications, which may be arranged under the following classes.

1. Chemical affinity unites several bodies, in any proportion whatsoever; their combination is therefore unlimited; for instance,

If water and ardent spirit be mingled together in any quantity, a chemical combination ensues; for the compound obtained has always a specific gravity different from the mean specific gravity of the fluids combined. Its bulk is likewise not the same as that of the fluids in a separate state.

The same is the case when liquid acids and water, or acids and ardent spirit, are combined together.

2. Chemical affinity combines several bodies to a certain extent or *maximum* only.

To this class belong all those bodies which are capable of saturation.

It is on this account that water can only dissolve a certain quantity of salt; ardent spirit a certain quantity of resin, &c.

The union of oxygen and hydrogen in the formation of water, belongs likewise to this class. It will likewise apply to many cases, in which bodies neutralize one another.

If we take a quantity of any of the dense acids diluted with water, for instance, sulphuric acid, and let fall into it a solution of an alkali, for example soda, by a little at a time, and examine the mixture after every addition of the alkali, we find for a considerable time it will exhibit the properties of an acid, it will have a sour taste, and convert vegetable blue colours into red; but if we continue to add greater quantities of soda, these acid properties will gradually diminish, and at last disappear altogether. At that point, neutralization is said to have taken place; if we continue to add more alkali, the mixture will gradually acquire alkaline properties; it will convert blue vegetables into green; it will have an urinous or alkaline taste, &c. These properties will become stronger, the greater the quantity of the soda is, which is added.

But if we proceed to evaporate the solution, in order to obtain crystals, we do not find these containing an indefinite proportion of soda: on the contrary, the salt appears to be truly neutral, and any slight excess of alkali present to be only mechanically mixed. It may be therefore said, that the sulphuric acid is saturated, as well as neutralized by soda. But the converse will not hold good, because a salt may be formed of the same ingredients, containing a considerable excess of acid, called therefore supersulphate of soda.

Again, take muriatic acid, and let fall into it gradually carbonate of lime, or magnesia; an effervescence will take place, for a chemical union ensues between the acid and the lime, or magnesia, while the carbonic acid, the other constituent of these bodies, becomes disengaged. But if we continue the addition of the carbonate of lime, or magnesia, until it produces no further effervescence; no chemical union will be obtained on adding more; this will fall to the bottom unaltered, for the combination is at its *maximum*.

3. Chemical affinity is capable of uniting some bodies in one proportion only; thus hydrogen and oxygen are known to form but one compound, namely water; whereas it combines other bodies in two, three, or more proportions; each of these combinations produces compounds, possessing peculiar properties.

This peculiarity of combination is highly important.

It is owing to this circumstance that both nature and art produce substances of the same principles, only combined in different proportions, which possess peculiar properties, widely different from each other. This is illustrated in the case of sulphuric acid and soda already noticed.

Another instance of this law may be seen in the following experiment:

Introduce one ounce of copper filings into four ounces of muriatic acid, contained in a medicine-phial of eight ounces capacity, cork it well, and let it stand undisturbed; the acid will soon acquire a greenish colour, which becomes deeper in proportion as the copper becomes dissolved; but in a few days, if the bottle be now and then agitated, the colour vanishes, and the solution at last becomes colourless.

If we now invert the bottle in mercury or water, and remove the cork under that fluid, a quantity of the mercury will rush in: an evident proof that part of the air contained in the phial has disappeared.

If we examine the remaining air, we shall find that it is incapable of supporting flame, and that it is nearly deprived of all its oxygen. If we now open the phial, the solution becomes again green.

The *rationale* of these phenomena is this: The quantity of oxygen which is present in the confined quantity of air in the empty part of the phial, combines with the copper to a certain degree, which then becomes soluble in the acid, and exhibits the green solution.

This oxide is gradually decomposed to a certain extent by some of the remaining copper, more of which is thus dissolved, and the solution becomes colourless. If more oxygen be admitted, the solution becomes green again as before.

4. In the formation of similar intimate chemical combinations, the same quantity of a given substance appears always requisite; and where there are different compounds of the same ingredients, if all contain the same quantity of one, the relative proportions of the other may be expressed by some of the small whole numbers, 1, 2, 3, 4, &c. Thus, if such quantities of potash and of soda be taken, as will both neutralize the same weight of sulphuric acid, each will also neutralize the same weight of nitric acid as the other. Hence the salts formed by the mutual decomposition of neutral salts are likewise neutral. This important law was first announced by Dr. Richter, in 1792. He also pointed out, that in the precipitation of metals by each other, the whole of the oxygen and acid are transferred; and that if the original solution were neutral, the new one is so likewise. Mr. Dalton, of Manchester, about the year 1802, adopted the opinion, that in these intimate compounds every particle of the one ingredient united to a corresponding particle of the other, or to some small number of particles.

The simplicity and beauty of this, which has been called the atomic theory, made a speedy and strong impression on chemists in general. Dr. Wollaston found it agree very well with the analyses of different salts, formed of the same acid and alkali. He took, for instance, equal weights of carbonate of potash, reduced one portion to subcarbonate by heating it to redness, then introducing them separately over mercury, and letting up diluted sulphuric acid to each, found the quantity of carbonic acid expelled from the subcarbonate exactly one half of that from the carbonate. Gay-Lussac, in 1808, first maintained, that gases unite in simple ratios of their volume, and where the compound is gaseous, that the condensation, if any, is also in a simple ratio. Thus 1 measure of oxygen unites with 2 of hydrogen to form water; 1 measure of nitrogen with 3 of hydrogen to form 2 measures of ammonia; equal measures of ammonia and muriatic acid to form muriate of ammonia. It appears too in many instances that a solid combining with a gas does not alter its volume, as when charcoal uniting to oxygen forms carbonic acid gas. Berzelius, Sir Humphrey Davy, and many other chemists, have since adduced numerous proofs of the correctness of the atomic theory: but from the difficulty of analysing bodies with sufficient precision, and still more from the readiness with which the ingredients often combine with each other, or with the resulting compounds, less intimately, and therefore in indeterminate proportions, it can hardly be expected that it should be established universally.

VIII. The energy of the chemical affinity of different bodies is modified in proportion to the ponderable quantities of the substances placed within the sphere of action.

It is obvious, from this, that the denomination of elective affinity is erroneous; since it supposes the union of one entire substance with another, to the exclusion of a third. But this is not the case; a mere division of action takes place in instances of this kind; that is to say, the substances act according to the quantity existing within the sphere of activity. The excess of quantity is capable of compensating the deficiency of the force of affinity. When, therefore, a compound body of two substances is acted on by a third, that part of the compound which is the subject of combination, is divided between the two remaining, not only in proportion to their respective degrees of affinity, but also according to their ponderable quantities, so that by varying this in either, the effect produced will be varied.

Thus Berthollet has proved, that in all cases a large quantity of a body is capable of abstracting a portion of another, from a small portion of a third, how weak soever the affinity between the first and second of these bodies may be, and how strong soever the affinity between the second and third. Thus potash is capable of abstracting part of the acid from oxalate of lime, phosphate of lime, and carbonate of lime. Soda and lime decompose partially sulphate of potash. Nitric acid subtracts part of the base from oxalate of lime, &c.

The following experiment, advanced by Berthollet, will prove this more clearly.

If equal parts, by weight, of potash and sulphate of barytes be boiled, in a small quantity of water, to dryness, it will be found that the sulphuric acid has been divided between the two bases in the compound ratio of their mass, and their force of affinity. The greater part of the sulphate of barytes will be found undecomposed; a small quantity of barytes will be found at liberty; most of the potash will also be uncombined, but a certain portion will be united with the sulphuric acid which the barytes has lost, in the form of sulphate of potash.

It is not merely in the instance stated here, that this division of one body between two others, according to their respective masses and affinities, takes place, there being scarcely any example to the contrary.

And as the affinities of bodies vary with their masses, it is obvious that, when we speak of the affinities of bodies, we ought to consider them as always acting in certain determinate proportions.

Aua'nte. (From αυαινω, to dry.) A dry disease, proceeding from a fermentation in the stomach, described by Hippocrates de Morbis.

Aua'pse. The same.

Au'chen. (From αυχεω, to be proud.) The neck, which, in the posture of pride, is made stiff and erect.

Auditory nerve. See *Nerve* and *Portio mollis.*

Auditory passage. See *Ear* and *Meatus auditorius internus.*

Augu'stum. An epithet given to several compound medicines.

Auli'scos. (From αυλος, a pipe.) A catheter, or clyster-pipe.

Au'los. The same.

AU'RA. (From αω, to breathe.) Any subtile vapour, or exhalation.

AU'RA EPILE'PTICA. A sensation which is felt by epileptic patients, as if a blast of cold air ascended from the lower parts towards the heart and head.

AU'RA SE'MINIS. The extremely subtile and vivifying portion of the semen virile, that ascends through the Fallopian tubes, to impregnate the ovum in the ovarium.

Au'ra vita'lis. So Helmont calls the vital heat.

Aura'ntia curassave'ntia. Curassoa, or Curassao apples, or oranges. The fruit so called seem to be the immature oranges, that by some accident have been checked in their growth. They are a grateful aromatic bitter, of a flavour very different from that of the peel of the ripe fruit, and without any acid; what little tartness they have when fresh, is lost in drying. Infused in wine, or brandy, they afford a good bitter for the stomach. They are used to promote the discharge in issues, whence their name of *issue peas*, and to give the flavour of hops to beer.

Aura'ntii ba'ccæ. Seville oranges. See *Citrus aurantium.*

Aura'ntii cortex. See *Citrus aurantium.*

AURA'NTIUM. (So called, *ab aureo colore*, from its golden colour, or from *Arantium*, a town of Achaia.) See *Citrus aurantium.*

AURI'CULA. (dim. of *auris*, the ear.) The external ear, upon which are several eminences and depressions, as the *helix*, *antihelix*, *tragus*, *antitragus*, *conchæ auriculæ*, *scapha*, and *lobulus*. See *Ear.*

Auri'cula judæ. Jew's ear. See *Peziza auricula.*

Auri′cula mu′ris. See *Hieracium.*

Auri′culæ co′rdis. The auricles of the heart. See *Heart.*

AURICULA′RIS. (*Auricularis,* sc. *digitus;* from *auris,* the ear; so called because people generally put it into the ear, when the hearing is obstructed.) The little finger.

Auri′ga. (A waggoner. Lat.) A bandage for the sides is so called because it is made like the traces of a waggon-horse. *Galen.*

Auri′go. (*Ab aureo colore;* from its yellow colour.) The jaundice. See *Icterus.*

Auripi′gmentum. (From *aurum,* gold, and *pigmentum,* paint; so called from its colour and its use to painters.) Yellow orpiment. See *Arsenic.*

AU′RIS. (From *aura,* air, as being the medium of hearing.) The ear, or organ of hearing. See *Ear.*

Au′ris leva′tor. See *Attollens aurem.*

Aurisca′lpium. (From *auris,* the ear, and *scalpo,* to scrape.) An instrument for cleansing the ear.

Au′rium so′rdes. The wax of the ears.

Au′rium tinni′tus. A ringing noise in the ears.

Auru′go. The jaundice.

AU′RUM. Gold.

Au′rum horizonta′le. Oil of cinnamon and sugar.

Au′rum lepro′sum. Antimony.

Au′rum musi′vum. A preparation of tin, sulphur, sal-ammoniac, and quicksilver.

Au′rum pota′bile. Gold dissolved and mixed with oil of rosemary, to be drank.

Au′rus Brazilie′nsis. An obsolete name of the Calamus aromaticus.

Authe′meron. (From *αυτος,* the same, and *ημερα,* a day.) A medicine which gives relief, or is to be administered the same day.

Autolitho′tomus. One who cuts himself for the stone.

Autocrate′ia. The healing power of nature. *Hippocrates.*

Auto′psia. (From *αυτος,* himself, and *οπ]ομαι,* to see.) Ocular evidence.

Auto′pyros. (From *αυτος,* itself, and *ϖυρος,* wheat.) Bread made with the meal of wheat, from which the bran has not been removed. *Galen.*

Auxilia′rii mu′sculi. The pyramidal muscles of the abdomen.

Ava′nsis. *Avante.* Indigestion.

AVELLA′NA. (From *Abella,* or *Avella,* a town in Campania, where they grew.) The hazel-nut.

Avella′na catha′rtica. Barbadoes nuts. A purgative.

Avella′na Mexicana. Cocoa and chocolate nut.

Avella′na purga′trix. Garden spurge.

AVE′NA. (From *aveo,* to covet; because cattle are so fond of it.) The oat.

1. The name of a genus of plants in the Linnæan system. Class, *Triandria.* Order, *Digynia.*

2. The pharmacopœial name of the oat.

Ave′na sati′va. The systematic name for the *avena* of the pharmacopœias. It is the seed which is commonly used, and called the oat. There are two kinds of oats: the black and the white. They have similar virtues, but the black are chiefly sown for horses. They are less farinaceous, and less nourishing, than rice, or wheat; yet afford a sufficient nourishment, of easy digestion, to such as feed constantly on them. In Scotland, and some of the Northern counties of England, oats form the chief bread of the inhabitants. They are much used in Germany; but, in Norway, oat bread is a luxury, among the common people. Gruels, made with the flour, or meal, called oatmeal, digest easily, have a soft mucilaginous quality, by which they obtund acrimony, and are used for common drink and food in fevers, inflammatory disorders, coughs, hoarseness, roughness, and exulceration of the fauces; and water-gruels answer all the purposes of Hippocrates' ptisan. Externally, poultices, with oatmeal, vinegar, and a very little oil, are good for sprains and bruises. Stimulant poultices, with the grounds of strong beer, mixed up with oatmeal, are made for tumours, &c. of a gangrenous tendency.

Ave′næ se′mina. See *Avena sativa.*

Avenacu. A Molucca tree, of a caustic quality.

Avens, common. See *Geum.*

AVENZOAR, a native of Seville, in Spain, who flourished about the beginning of the twelfth century; he was made physician to the king, and is said, but on imperfect evidence, to have attained the uncommon age of 135. He prepared his own medicines, and practised surgery, as well as physic. His principal work was a compendium of the practice of medicine, called "Al Theiser," containing some diseases not elsewhere described, and numerous cases candidly related. He was called the Experimenter, from his careful investigation of the powers of medicines by actual trial.

AVERROES, an eminent philosopher and physician, born about the middle of the 12th century, at Corduba, in Spain. He studied medicine under Avenzoar, but does not appear to have been much engaged in the practice of it, his life exhibiting the most extraordinary vicissitudes of honours bestowed upon him as a magistrate, and persecutions, which he underwent for religion. He appears to have first observed, that the small-pox occurs but once in the same person. His principal medical work, called the "Universal," is a compendium of physic, mostly collected from other authors. He died about the year 1206.

AVICENNA, a celebrated philosopher and physician, born in Chorasan, in the year 980. He studied at Bagdat, obtained a degree, and began to practise at 18: and he soon attained great wealth and honour in the court of the caliph. But during the latter part of his life residing at Ispahan, after several years spent in travelling, he impaired his constitution by intemperance, and died of a dysentery in his 58th year. His chief work on medicine, called "Canon Medicinæ," though mostly borrowed from the Greek or other preceding writers, and in a very diffuse style, acquired great reputation, and was taught in the European colleges till near the middle of the 17th century.

AVICE′NNIA. The name of a genus of plants in the Linnæan system. Class, *Didynamia.* Order, *Angiospermia.*

Avicenni′a tomento′sa. The systematic name for the plant which affords the Malacca bean, or *Anacardium orientale* of the pharmacopœias. The fruit, or nut, so called, is of a shining black colour, heart-shaped, compressed, and about the size of the thumb-nail. It is the produce of the *Avicennia tomentosa; foliis cordato-ovatis, subtus tomentosis,* of Linnæus. It is now deservedly forgot in this country.

Avigato Pear. See *Laurus persea.*

AXI′LLA. (*Axilla, atzil,* Heb. Scaliger deduces it from *ago,* to act; in this manner, ago, axo, axa, axula, axilla.) The cavity under the upper part of the arm, called the arm-pit.

Axillary arteries. *Arteriæ axillares.* The axillary arteries are continuations of the subclavians, and give off, each of them, in the axilla, four mammary arteries, the subscapular, and the posterior and anterior circumflex arteries, which ramify about the joint.

Axillary nerve. Articular nerve. A branch of the brachial plexus, and sometimes of the radial nerve. It runs outwards and backwards, around the neck of the humerus, and is lost in the muscles of the scapula.

Axillary veins. *Venæ axillares.* The axillary veins receive the blood from the veins of the arm, and evacuate it into the subclavian vein.

A′xis. (From *ago,* to act.) See *Dentatus.*

AXU′NGIA. (From *axis,* an axle-tree, and *unguo,* to anoint.) Hog's lard.

Axu′ngia cura′ta. Purified hog's lard.

Axu′ngia de mu′mmia. Marrow.

A′zac. (Arab.) Gum ammoniac.

Aza′gor. Verdigrise.

Azamar. Native cinnabar. Vermilion.

Azed. A fine kind of camphire.

AZOT. (From α, priv. and ζεω, to live; because it is unfit for respiration.) See *Nitrogen.*

Azot, gaseous oxide of. See *Nitrogen, gaseous oxide of.*

A′zoth. An imaginary universal remedy.

A′zub. Alum.

Azu′rium. Quicksilver, sulphur, and sal-ammoniac.

A′zyges. (From α, priv. and ζυγος, a yoke.) The os sphenoides was so called, because it has no fellow.

A′ZYGOS. (From α, priv. and ζυγος, a yoke; because it has no fellow.) Several single muscles, veins, bones, &c. are so called.

A′zygos morga′gni. A muscle of the mouth.

A′zygos proce′ssus. A process of the os sphenoides.

A′ZYGOS U′VULÆ. *Palato-staphilinus* of Douglas. *Staphilinus,* or *Epistaphilinus* of Winslow. A muscle of the uvula, which arises at one extremity of the suture which joins the palate bones, runs down the whole length of the velum and uvula, resembling an earth-worm, and adhering to the tendons of the circumflexi. It is inserted into the tip of the uvula. Its use is to raise the uvula upwards and forwards, and to shorten it.

A′zygos vein. *Vena azygos. Vena sine pari.* This vein is situated in the right cavity of the thorax, upon the dorsal vertebræ. It receives the blood from the vertebral, intercostal, bronchial, pericardiac, and diaphragmatic veins, and evacuates it into the vena cava superior.

B.

Babuzica′rius. (From βαβαζω, to speak inarticulately.) The incubus, or nightmare; so called because, in this disorder, the person is apt to make an inarticulate and confused noise.

Ba′cca monspelie′nsis. *Inula dysenterica.*

Bacca′lia. (*à baccharum copiâ,* because it abounds in berries.) The bay, or laurel-tree.

Ba′ccæ bermude′nses. See *Sapindus saponaria.*

Ba′ccæ juni′peri. Juniper berries. See *Juniperus.*

Ba′ccæ lau′ri. Laurel berries. See *Laurus.*

Ba′ccæ norla′ndicæ. See *Rubus Arcticus.*

Ba′ccæ piscato′riæ. See *Menispermum cocculus.*

Ba′ccharis. (From *bacchus*, wine; from its fragrance resembling that liquor.) See *Inula dysenterica.*

Bacher's pills. *Pilulæ tonicæ Bacheri.* A celebrated medicine in France, employed for the cure of dropsies. Their principal ingredient is the extract of melampodium, or black hellebore.

Ba′cchia. (From *bacchus*, wine; because it generally proceeds from hard drinking and intemperance.) *Gutta rosacea.* A name given by Linnæus to a pimpled face.

BACCIUS, Andrew, a native of Ancona, practised medicine at Rome towards the end of the 16th century, and became physician to Pope Sixtus V. He appears to have had great industry and learning from his numerous publications; of which the chief, "De Thermis," gives an extensive examination of natural waters.

Ba′cculi. Is used, by some writers, for a particular kind of lozenges, shaped into little short rolls. Hildanus likewise uses it for an instrument in surgery.

Ba′coba. The *Banana.*

BACTISHUA, George, was a celebrated physician of Chorasan, distinguished also for his literary attainments. He was successful in curing the reigning caliph of a complaint of the stomach, which brought him into great honour; he translated several of the ancient medical authors into the Arabian language; and many of his observations are recorded by Rhazes and other succeeding physicians. His son, *Gabriel*, was in equal estimation with the famous Haroun Al Raschid, whom he cured of apoplexy by blood-letting, in opposition to the opinion of the other physicians.

Badia′ga. A kind of sponge usually sold in Russia, the powder of which is said to take away the livid marks of blows and bruises within a few hours. It is only described by Bauxbaum, and its nature is not properly understood.

Badian se′men. The seed of a tree which grows in China, and smells like aniseed. The Chinese (and Dutch, in imitation of them) sometimes use the badiane to give their tea an aromatic taste. See *Illicium anisatum.*

Badi′za a′qua. See *Bath waters.*

Badranum semen. Indian aniseed.

Badu′cca. (Indian.) A species of capparis.

Ba′dzcher. An antidote.

Bæ′os. (Βαιος.) In Hippocrates it means few; but in P. Ægineta, it is an epithet for a poultice.

BAGLIVI, George, born at Ragusa in 1668, after graduating at Padua, and improving himself greatly by travelling throughout Italy, was made professor of medicine and anatomy at Rome. In 1696, he published an excellent work on the practice of physic, condemning the exclusive attachment to theory, and earnestly recommending the Hippocratic method of observation; which, he maintained, assisted by the modern improvements in anatomy and physiology, would tend greatly to the advancement of medicine. He has left also several other tracts, though he died at the early age of 38.

BAGNIGGE WELLS. A saline mineral spring in London, resembling the Epsom water. In most constitutions, three half-pints is considered a full dose for purging.

Ba′gnio. (From *bagno*, Ital.) A bathing or sweating-house.

Ba′hei coyo′lli. Ray takes it to be the *Areca*, or *Faufel.*

Ba′hel schu′lli. An Indian-tree. See *Genista.*

Ba′iac. White lead.

BAILLOU, Guillaume de, commonly called *Ballonius*, was born in 1538 at Paris, where he graduated, and attained considerable eminence. He was very active in the contest for precedence between the physicians and surgeons, which was at length decided in favour of the former. His writings are numerous, though not now much esteemed; but he appears to have been the first who properly discriminated between gout and rheumatism.

Ba′la. The plantain-tree.

Balæ′na macroce′phala. (Βαλαινα: from *βαλλω*, to cast, from its power in casting up water; and *μακροκεφαλος*: from *μακρος*, long, and *κεφαλη*, a head; from the length of its head.) The systematic name of a species of whale.

Balani′num o′leum. Oil of the ben-nut.

Balanoca′stanum. (From *βαλανος*, a nut, and *καϛανον*, a chesnut; so called from its tuberous root.) The *bunium bulbocastanum*, or earth-nut: which see.

Ba′lanos. *Balanus.* (From *βαλλω*, to cast; because it sheds its fruit upon the ground.) 1. An acorn.

2. Hippocrates, in his Treatise de Affectionibus, expresses by it the oak.

3. Theophrastus uses it sometimes, to express any glandiferous tree.

4. From the similitude of form, this word is used to express suppositories and pessaries.

5. A name of the glans penis.

BALAU′STIUM. (From *βαλιος*, various, and *αυω*, to dry; so called from the variety of its colours, and its becoming soon dry; or from *βλαϛανω*, to germinate.)

Balaustia. A large rose-like flower, of a red colour, the produce of the plant from which we obtain the granatum. See *Punica granatum.*

BALBU'TIES, (From βαϐαζω, to stammer; or from *balbel,* Heb. to stammer.) A defect of speech; properly, that sort of stammering where the patient sometimes hesitates, and immediately after, speaks precipitately. It is the *Psellismus Balbutiens* of Cullen.

Bali'sta. (From βαλλω, to cast.) The astragulus, a bone of the foot, was formerly called os balistæ, because the antients used to cast it from their slings.

Balloo'n. (*Ballon,* or *balon,* French.) A large glass receiver in the form of a hollow globe. For certain chemical operations *balloons* are made with two necks, placed opposite to each other; one to receive the neck of a retort, and the other to enter the neck of a second *balloon:* this apparatus is called *enfiladed balloons.* Their use is to increase the whole space of the receiver, because any number of these may be adjusted to each other. The only one of these vessels which is generally used, is a small oblong *balloon* with two necks, which is to be luted to the retort, and to the receiver, or great *balloon;* it serves to remove this receiver from the body of the furnace, and to hinder it from being too much heated.

Ballo'te. (From βαλλω, to send forth, and ους, ωτος, the ear; because it sends forth flowers like ears.) *Ballota.* Stinking horehound. A nettle-like plant. The *ballote nigra* of Linnæus.

Balm. See *Melissa.*

Balm of Gilead. See *Dracocephalum.*

Balm of Mecca. See *Amyris opobalsamum.*

Balm, Turkey. See *Dracocephalum.*

Balmoney. See *Æthusa meum.*

BA'LNEUM. A bath, or bathing-house. See *Bath.*

Ba'lneum anima'le. The wrapping any part of an animal, just killed, round the body, or a limb.

BA'LNEUM ARE'NÆ. A sand-bath for chemical purposes. See *Bath.*

BA'LNEUM CA'LIDUM. A hot-bath. See *Bath.*

BA'LNEUM FRI'GIDUM. A cold bath. See *Bath.*

BA'LNEUM MARI'Æ. *Balneum maris.* A warm-water bath. See *Bath.*

BA'LNEUM MEDICA'TUM. A bath impregnated with drugs.

Ba'lneum si'ccum. *Balneum cinereum.* A dry bath, either with ashes, sand, or iron filings.

Ba'lneum sulphu'reum. A sulphurous bath.

BA'LNEUM TE'PIDUM. A tepid bath. See *Bath.*

BA'LNEUM VAPO'RIS. A vapour bath.

BA'LSAM. (*Balsamum.* From *baal samen,* Hebrew.) The term balsam was antiently applied to any strong-scented, natural vegetable resin of about the fluidity of treacle, inflammable, not miscible with water, without addition, and supposed to be possessed of many medical virtues. All the turpentines, the Peruvian balsam, copaiba balsam, &c. are examples of natural balsams. Besides, many medicines compounded of various resins, or oils, and brought to this consistence, obtained the name of balsam. Latterly, however, the term has been restricted to those resins which contain the Benzoic acid. Of these only four are commonly known, the gum benzoin, balsam of Tolu, that of Peru, and storax.

Balsam apple, male. The fruit of the *Momordica elaterium* of Linnæus. See *Momordica elaterium.*

Balsam, artificial. Compound medicines are thus termed which are made of a balsamic consistence and fragrance. They are generally composed of expressed or ethereal oils, resins, and other solid bodies, which give them the consistence of butter. The basis, or body of them, is expressed oil of nutmeg, and frequently wax, butter, &c. They are usually tinged with cinnabar and saffron.

Balsam, Canary. See *Dracocephalum.*

Balsam of Canada. See *Pinus Balsamea.*

Balsam of Copaiba. See *Copaifera officinalis.*

Balsam, natural. A resin which has not yet assumed the concrete form, but still continues in a fluid state, is so called, as common turpentine, balsamum copaiva, peruvianum, tolutanum, &c.

Balsam, Peruvian. See *Myroxylon Peruiferum.*

Balsam of sulphur. See *Balsamum sulphuris.*

Balsam of Tolu. See *Toluifera balsamum.*

Balsam, Turkey. See *Dracocephalum.*

Balsama'tio. (From *balsamum,* a balsam.) The embalming of dead bodies.

Balsa'mea. (From *balsamum,* balsam.) The balm of Gilead fir; so called from its odour. See *Pinus balsamea.*

Balsamelæ'on. (From *balsamum,* balsam, and ελαιον, oil.) Balm of Gilead, or true balsamum Judaicum.

Ba'lsami o'leum. Balm of Gilead.

BALSA'MICA. (*Balsamica,* sc. *medicamenta;* from ϐαλσαμον, balsam.) Balsamics. A term generally applied to substances of a smooth and oily consistence, which possess emollient, sweet, and generally aromatic qualities. Hoffman calls those medicines by this name, which are hot and acrid, and also the natural balsams, stimulating gums, &c. by which the vital heat is increased. Dr. Cullen speaks of them under the joint title of *balsamica* et *resinosa*, considering that turpentine is the basis of all balsams.

Balsami'fera Brazilie'nsis. The balsam copaiba tree.

Balsami'fera Indica'na. The Peruvian balsam tree.

Balsami'ta fœmi'nea. See *Achillea ageratum*.

Balsami'ta lu'tea. The *polygonum persicaria* of Linnæus; which see.

Balsami'ta mi'nor. Sweet maudlin.

Balsami'ta major. } See *Tanacetum Balsamita*.
Balsami'ta mas. }

BA'LSAMUM. (From *baal samen*, Heb. the prince of oils.) A balsam. See *Balsam*.

Ba'lsamum Ægypti'acum. See *Amyris opobalsamum*.

Ba'lsamum America'num. See *Myroxylon Peruiferum*.

Ba'lsamum ano'dynum. A preparation made from tacamahacca, distilled with turpentine and soap liniment, and tincture of opium.

Ba'lsamum alpi'num. See *Amyris opobalsamum*.

Ba'lsamum antimo'nii. A remedy formerly applied to cancer.

Ba'lsamum arcæ'i. A preparation composed of gum-elemi and suet.

Ba'lsamum Asia'ticum. See *Amyris opobalsamum*.

Ba'lsamum Brazilie'nse. See *Pinus balsamea*.

Ba'lsamum Canade'nse. See *Pinus balsamea*.

Ba'lsamum cepha'licum. A distillation of oils, nutmeg, cloves, amber, &c.

Ba'lsamum commendato'ris. A composition of storax, benzoe, myrrh, aloes, &c.

Ba'lsamum Copa'ibæ. See *Copaifera officinalis*.

Ba'lsamum embryonum. A preparation of aniseed.

Ba'lsamum genui'num antiquo'rum. See *Amyris opobalsamum*.

Ba'lsamum Gileade'nse. See *Amyris opobalsamum*.

Ba'lsamum guaia'cinum. Balsam of Peru and spirits of wine.

Ba'lsamum Guido'nis. The same as balsamum anodynum.

Ba'lsamum Hunga'ricum. A balsam prepared from a coniferous tree on the Carpathian mountains.

Ba'lsamum Juda'icum. See *Amyris opobalsamum*.

Ba'lsamum Locate'lli. (*Locatelli*; so called from its inventor Lucatellus.) *Balsamum Lucatelli*. A preparation made of oil, turpentine, wax, and red saunders; now disused; formerly exhibited in coughs of long standing.

Ba'lsamum mas. The herb costmary. See *Tanacetum balsamita*.

Ba'lsamum e Me'cca. See *Amyris opobalsamum*.

Ba'lsamum Mexica'num. See *Myroxylon Peruiferum*.

Ba'lsamum no'vum. A new balsam from a red fruit in the West Indies.

Ba'lsamum odori'ferum. A preparation of oil, wax, and any essential oil.

Ba'lsamum Pe'rsicum. A balsamum composed of storax, benzoe, myrrh, and aloes.

Ba'lsamum Peruvia'num. See *Myroxylon peruiferum*.

Ba'lsamum rackasira. This balsam, which is inodorous when cold, but of a smell approaching to that of Tolu balsam when heated, is brought from India in gourd-shells. It is slightly bitter to the taste, and adheres to the teeth, on chewing. It is supposed to be one of the factitious balsams, and is scarcely ever prescribed in this country.

Ba'lsamum sa'mech. A factitious balsam, composed of tartar, dulcified by spirits of wine.

Ba'lsamum sapona'ceum. A name given to the preparation called opodeldoc.

Ba'lsamum satu'rni. The remedy so named is prepared by dissolving the acetate of lead in oil of turpentine, and digesting the mixture till it acquires a red colour. This is found to be a good remedy for cleansing foul ulcers; but it is not acknowledged in our dispensatories.

Ba'lsamum sty'racis Benzoi'ni. Gum-benzoin is so called. See *Styrax Benzoin*.

Ba'lsamum su'ccini. Oil of amber.

Ba'lsamum su'lphuris. A solution of sulphur in oil.

Ba'lsamum su'lphuris anisa'tum. Terebinthinated balsam of sulphur, and oil of aniseed.

Ba'lsamum su'lphuris Barbade'nse. Sulphur boiled with Barbadoes tar.

Ba'lsamum su'lphuris cra'ssum. Thick balsam of sulphur.

Ba'lsamum su'lphuris terebinthina'tum. This is made by digesting the sulphur with oil of turpentine; it is now confined to veterinary medicine.

Ba'lsamum su'lphuris si'mplex. Sulphur boiled with oil.

Ba'lsamum Syri'acum. The balm of Gilead. See *Amyris opobalsamum*.

Ba'lsamum Toluta'num. See *Toluifera balsamum*.

Ba'lsamum trauma'ticum. Vulnerary balsam. A form of medicine prescribed in the London Dispensatory, intended to supply the place of the tincture commonly called Friar's balsam, so famous for curing old ulcers. The London College have named it Tinctura Benzoini composita.

Ba'lsamum universa'le. A name given to the unguentum saturninum of old pharmacopœias.

Ba'lsamum ve'rum. See *Amyris opobalsamum*.

Ba'lsamum vi'ride. Linseed-oil, turpentine, and verdigrise mixed together.

Ba'lsamum vi'tæ Hoffma'nni. *Beaume de vie.* An artificial balsam, so named from its inventor, and composed of a great variety of the warmest and most grateful essential oils, such as nutmegs, cloves, lavender, &c. with balsam of Peru, dissolved in highly rectified spirit of wine; but it is now greatly abridged in the number of ingredients, and but little used.

Balzoi'num. The gum-benjamin.

Bamba'lio. (From βαμβαινω, to speak inarticulately.) A person who stammers, or lisps.

Bambo'o. (Indian.) The young shoots of the *arundo bambos* of Linnæus, which are prepared by the natives of both Indies with vinegar, garlic, pepper, &c. into a very excellent pickle, which promotes the appetite, and assists digestion.

Ba'mia moscha'ta. See *Hibiscus.*

Bamier. The name of a plant common in Egypt, the husk of which they dress with meat, and, from its agreeable flavour, make great use of it in their ragouts.

Ban a'rbor. The coffee-tree.

BANA'NA. (Indian.) *Bananeira. Ficoides. Ficus Indica. Musa fructu cucumerino breviori. Senoria. Pacœira.* The Banana, or Plantain-tree. The most remarkable species of this genus of plants are,

1. The *paradisaica*, or plantain.
2. The *musa sapientum*, or banana-tree.

Both are among the most important productions of the earth. The first sort is cultivated in all the islands of the West Indies, where the fruit serves the Indians for bread; and some of the white people also prefer it to most other things, especially to the yams and cassada bread. This tree is cultivated, on a very extensive scale, in Jamaica; without the fruit of which, Dr. Wright says, the island would scarcely be habitable, as no species of provision would supply their place. Even flour, or bread itself, would be less agreeable, and less able to support the laborious negro, so as to enable him to do his business, or to keep in health. Plantains also fatten horses, cattle, swine, dogs, fowls, and other domestic animals. The leaves, being smooth and soft, are employed as dressings after blisters. The water from the soft trunk is astringent, and employed by some to check diarrhœas. Every other part of the tree is useful in different parts of rural economy. The leaves are used as napkins and tablecloths, and are food for hogs. The second sort, musa sapientum, or banana tree, differs from the paradisaica, in having its stalks marked with dark purple stripes and spots. The fruit is shorter, straighter, and rounder; the pulp is softer, and of a more luscious taste. It is never eaten green; but, when ripe, it is very agreeable, either eaten raw or fried in slices, as fritters, and is relished by all ranks of people in the West Indies. Both the above plants were carried to the West Indies from the Canary islands; whither, it is believed, they had been brought from Guinea, where they grow naturally.

Bananei'ra. See *Banana.*

Ba'ncia. The Elaphoboscum, or wild parsnip.

BANDAGE. *Deligatio. Fascia.* An apparatus consisting of one or several pieces of linen, or flannel, and intended for covering or surrounding parts of the body for surgical purposes. Bandages are either simple or compound. The chief of the simple are the circular, the spiral, the uniting, the retaining, the expellent, and the creeping. The compound bandages used in surgery, are the T bandage, the suspensory one, the capistrum, the eighteen-tail bandage, and others, to be met with in surgical treatises.

Bandu'ra. A plant which grows in Ceylon, whose root is said to be astringent.

Bangu'e. *Bange.* A species of opiate in great use throughout the East, for its intoxicating qualities. It is the leaf of a kind of wild hemp, growing in the countries of the Levant, and made into powder, pills, or conserves.

Ba'nica. The wild parsnip.

Bani'lia.
Bani'las. } See *Epidendrum.*

Bao'bab. *Bahobab.* A species of the genus of plants called by Linnæus *Adansonia:* which see.

Ba'ptica co'ccus. Kermes berries.

Baptiste'rium. (From βαπτω, to immerge.) A bath, or repository of water, to wash the body.

Bapti'strum. (From βαπτω, to dye.) A species of wild mustard, so called from its reddish colour.

Ba'rac. (From *borak,* Arabian, splendid.) *Barach panis.* Nitre. According to Rulandus, nitrum salis.

Ba'ras. (Arabian.) In M. A. Severinus, it is synonymous with Alphus, or Leuce.

Bara'thrum. (Arabian.) Any cavity or hollow place.

BA'RBA. (From *barbarus,* because wild nations are usually unshaven.) 1. The beard of man.

2. Some vegetables have the specific name of *barba,* whose ramifications are bushy, like a beard, as *barba jovis,* &c.

Ba'rba aro'nis. The arum.

Ba'rba ca'præ. The ulmaria.

Ba'rba hi'rci. The tragopogon.

Ba'rba jo'vis. Jupiter's beard, or the silver bush. Also a name of the sempervivum majus, and of a species of anthyllis.

Barba'does che'rry. The fruit of the *malphigia glabra* of Linnæus, resembling the inferior sorts of our cherries.

Barbádoes nut. See *Jatropha curcas.*

BARBA'DOES TAR. (So named from the island from which it is chiefly procured.) The use of this article in medicine is limited to its external application, at times, in paralytic cases.

Barba'rea. (From St. Barbary, who is said to have found its virtues.) See *Erysimum barbarea.*

Barba'ria. *Barbaricum.* An obsolete term formerly applied to rhubarb.

Barbaro'ssæ pi'lula. Barbarossa's pill. An ancient composition of quicksilver, rhubarb, diagridium, musk, amber, &c. It was the first internal mercurial medicine which obtained any real credit.

Ba'rbarum. The name of a plaster in Scribonius Largus.

Barbatina. A Persian vermifuge seed.

Ba'rbel. *Barbo.* An oblong fish, resembling the pike, the eating of whose roe often brings on the cholera.

Barberry. See *Berberis.*

BARBEYRAC, Charles, a French physician of the 17th century, who graduated and settled at Montpelier, where he acquired great celebrity. He died in 1699, at the age of about 70, having published little, except a good account of the diseases of the chest and stomach in females. Mr. Locke, who became intimate with him abroad, considered him very similar in his manners and opinions to Sydenham. His practice is said to have been distinguished for simplicity and energy.

Barbo'ta. The barbut. A small river-fish. It is remarkable for the size of its liver, which is esteemed the most delicate part of it.

BARDA'NA. (From *bardus,* foolish; because silly people are apt to throw them on the garments of passengers, having the property of sticking to whatever they touch.) Burdock. See *Arctium.*

BARE'GE WATER. The small village of Barege, celebrated for its thermal waters, is situated on the French side of the Pyrenees, about half way between the Mediterranean and the Bay of Biscay. The hot springs are four in number. They have all the same component parts, but differ somewhat in their temperature, and in the quantity of sulphur, the hottest being most strongly penetrated with this active ingredient. The coolest of these waters raises Fahrenheit's thermometer to 73 deg.; the hottest to 120 deg. Barege waters are remarkable for a very smooth soapy feel; they render the skin very supple and pliable, and dissolve perfectly well soap and animal lymph; and are resorted to as a bath in resolving tumours of various kinds, rigidities, and contractions of the tendons, stiffness of the joints, left by rheumatic and gouty complaints, and are highly serviceable in cutaneous eruptions. Internally taken, this water gives considerable relief in disorders of the stomach, especially attended with acidity and heart-burn, in obstinate colics, jaundice, and in gravel, and other affections of the urinary organs.

Bari'glia.
Bari'lla. } See *Soda impura.*
Bari'llor.

BARK. A term very frequently employed to signify, by way of eminence, Peruvian bark. See *Cinchona.*

Bark, Carribæan. See *Cinchona Caribæa.*

Bark, Jamaica. See *Cinchona Caribæa.*

Bark, Peruvian. See *Cinchona.*

Bark, red. See *Cinchona oblongifolia.*

Bark, yellow. See *Cinchona cordifolia.*

Barley. See *Hordeum.*

Barley, caustic. See *Cevadilla.*

Barley, pearl. See *Hordeum.*

Barm. A name given to yeast.

BARNET WATER. It is of a purging kind, of a similar quality to that of Epsom, and about half its strength.

BARO'METER. (From *βαρος,* weight, and *μετρον,* measure.) An instrument to determine the weight of the air; it is commonly called a weather-glass.

Baro'nes. Small worms; called also Nepones.

Baro'ptis. A black stone, said to be an antidote to venomous bites.

Ba'ros. (Βαρος.) Gravity.

1. Hippocrates uses this word to express by it, an uneasy weight in any part.

2. It is also the Indian name for a species of camphire, which is distilled from the roots of the true cinnamon-tree.

Ba'rrenness. The same as sterility.

BA'RTHOLINE, Thomas, was born at Copenhagen in 1616. After studying in various parts of Europe, particularly Padua, and graduating at Basil, he became professor of anatomy in his native city; in which office he greatly distinguished himself, as well as in many other branches of learning. He was the first who described the lymphatics with accuracy; though some of these vessels, as well as the lacteals and thoracic duct, had been before discovered by other anatomists. Besides many learned works which he published, several others were unfortunately destroyed by fire in 1670; and he particularly regretted a dissertation on the ancient practice of midwifery, of which an outline was afterwards published by his son *Caspar.* Of those which remain, the most esteemed are, his epistolary correspondence with the most celebrated of his cotemporaries; his collection of cases where fœtuses have been discharged by preternatural outlets; and the "Medical and Philosophical Transactions of Copenhagen," enriched by the communications of many correspondents: this last work was in four volumes, published within the ten years preceding his death, which happened in 1680; and a fifth was afterwards added by his son.

Bartholinia'næ gla'ndulæ. See *Sublingual glands.*

Barycoi'a. (From *βαρυς,* heavy, and *ακουω,* to hear.) Deafness, or difficulty of hearing.

Baryoco'ccalon. (From βαρυς, heavy, and κοκκαλος, a nut; because it gives a deep sound.) A name for the stramonium.

Barypho'nia. (From βαρυς, dull, and φωνη, the voice.) A difficulty of speaking.

BARY'TES. (From βαρυς, heavy; so called because it is very ponderous.) *Cauk. Calk. Terra ponderosa. Baryt.* Ponderous earth. Heavy earth.

Barytes does not exist pure in nature. It is always found in combination with sulphuric or carbonic acid. United with the sulphuric acid, it forms the mineral called *sulphate of barytes*, or *barŏselenite*. It is found in Staffordshire, Derbyshire, &c. When united to carbonic acid, it is called *aërated barytes*, or *carbonate of barytes*, found at Anglezark, near Chorley, in Lancashire. Both combinations are met with regularly crystallized and amorphous.

Pure barytes has a much stronger affinity than any other body for sulphuric acid; it turns blue tincture of cabbage green. It is entirely infusible by heat alone, but melts when mixed with various earths. Its specific gravity is 4.000. It changes quickly in the air, swells, becomes soft, and falls into a white powder, with the acquisition of about one-fifth of its weight. This slaking is much more active and speedy than that of lime. It combines with phosphorus, which compound decomposes water rapidly. It unites to sulphur by the dry and humid way. It has a powerful attraction for water, which it absorbs with a hissing noise and consolidates it strongly. It is soluble in twenty times its weight of cold, and twice its weight of boiling water. Its crystals are long four-sided prisms of a sattin-like appearance. It is a deadly poison to animals.

Method of obtaining pure Barytes. — 1. Take native carbonate of barytes; reduce it to a fine powder and dissolve it in a sufficient quantity of diluted nitric acid; evaporate this solution till a pellicle appears, and then suffer it to crystallize in a shallow bason. The salt obtained is nitrate of barytes; expose this nitrate of barytes to the action of heat in a china cup, or silver crucible, and keep it in a dull red heat for at least one hour; then suffer the vessel to cool, and transfer the greenish solid contents, which are pure barytes, into a well-stopped bottle. When dissolved in a small quantity of distilled water, and evaporated, it may be obtained in a beautiful crystalline form.

In this process the nitric acid, added to the native carbonate of barytes, unites to the barytes, and expels the carbonic acid, and forms nitrate of barytes; on exposing this nitrate to heat, it parts with its nitric acid, which becomes decomposed into its constituents, leaving the barytes behind.

2. Pure barytes may likewise be obtained from its sulphate. For this purpose, boil powdered sulphate of barytes in a solution of twice or three times its weight of carbonate of potash, in a Florence flask, for about two hours; filter the solution, and expose what remains on the filter to the action of a violent heat.

In this case, the sulphuric acid of the barytes unites to the potash, and the carbonic acid of the latter joins to the barytes; hence sulphate of potash and carbonate of barytes are obtained. The former is in solution and passes through the filter; the latter is insoluble, and remains behind. From this artificial carbonate of barytes, the carbonic acid is driven off by heat.

Barytæ Murias. *Terra ponderosa salita.* The muriate of barytes is a very acrid and poisonous preparation. In small doses it proves sudorific, diuretic, deobstruent, and alterative; in an over-dose, emetic, and violently purgative. The late Dr. Crawford found it very serviceable in all diseases connected with scrophula; and the Germans have employed it with great success in some diseases of the skin and viscera, and obstinate ulcers. The dose of the saturated solution in distilled water, is from five to fifteen drops for children, and from fifteen to twenty for adults.

Basaal. (Indian.) The name of an Indian tree. A decoction of its leaves, with ginger, in water, is used as a gargle in disorders of the fauces. The kernels of the fruit kill worms. *Ray's Hist.*

BASA'LTES. (In the Æthiopic tongue, this word means *iron*, which is the colour of the stone.) A heavy and hard kind of stone, chiefly black, or green. It frequently contains iron, has a flinty hardness, is insoluble by acids, and is fusible by fire. The most remarkable property of this substance is its figure, being never found in strata, like other marbles, but always standing up in the form of regular angular columns, composed of a number of joints, one placed upon and nicely fitted to another, as if formed by the hands of a skilful architect. Some regard this fusible substance as a volcanic production; others have supposed that it was formed from water. The Giant's Causeway, in the county of Antrim, in Ireland, and the rock of Pereniere, near St. Santdoux, in Auvergne, are formed of these stones. The distinctive characters of basaltes are, a regular form; hardness sufficient to give fire with steel; and a cinereous, gray colour, inclining to black.

Basani'tes. (From βασανιζω, to find out.) A stone said, by Pliny, to contain a bloody juice, and useful in diseases of the liver: also a stone upon which, by some, the purity of gold was formerly said to be tried, and of which medical mortars were made.

Base, acidifiable. See *Acid.*

Base, acidifying. See *Acid.*

Basia'tio. (From *basio*, to kiss.) Venereal connection between the sexes.

Basia'tor. See *Orbicularis oris*.

Basil. See *Ocimum basilicum*.

Basila're os. (*Basilaris*; from βασιλευς, a king.) Several bones were so termed by the antients; as the sphenoid and occipital bones.

BASILA'RIS ARTE'RIA. Basilary artery. An artery of the brain. So called because it lies upon the basilary process of the occipital bone. It is formed by the junction of the two vertebral arteries within the skull, and runs forwards to the sella turcica along the *pons varolii*, which it supplies, as well as the adjacent parts, with blood.

Basila'ris proce'ssus. Basilary process. See *Occipital bone*.

Basilia'ris apo'physis. The great apophysis of the os occipitis.

Basi'lica media'na. See *Basilica vena*.

Basi'lica nux. The walnut.

BASI'LICA VE'NA. The large vein that runs in the internal part of the arm, and evacuates its blood into the axillary vein. The branch which crosses, at the head of the arm, to join this vein, is called the *basilic median*. They may either of them be opened in the operation of blood-letting.

Basilicon ointment. See *Basilicum unguentum*.

Basi'licum. (From βασιλικος, royal; so called from its great virtues.) *Ocimum. Basil*. See *Ocimum Basilicum*.

Basi'licum ungue'ntum. *Unguentum basilicum flavum*. An ointment popularly so called from its having the ocimum basilicum in its composition. It came afterwards to be composed of wax, resin, &c. and is now called ceratum resinæ.

Basi'licus pu'lvis. The royal powder. A preparation formerly composed of calomel, rhubarb, and jalap. Many compositions were, by the antients, so called, from their supposed pre-eminence.

Basili'dion. An itchy ointment was formerly so called by Galen.

Ba'silis. A name formerly given to collyriums of supposed virtues, by Galen.

Basili'scus. (From βασιλευς, a king.) The basilisk, or cockatrice, a poisonous serpent; so called from a white spot upon its head, which resembles a crown. Also the philosopher's stone, and corrosive sublimate.

Basio-cerato-chondro-glo'ssus. See *Hyoglossus*.

Basio-glo'ssum. See *Hyoglossus*.

Basio-pharyngæ'us. See *Constrictor pharyngis medius*.

BA'SIS. (From βαινω, to go: the support of any thing, upon which it stands or goes.) 1. This word is frequently applied anatomically to the body of any part, or to that part from which the other parts appear, as it were, to proceed, or by which they are supported.

2. In pharmacy it signifies the principal ingredient.

Ba'sis ce'rebri. A term applied formerly to the palatum.

Ba'sis co'rdis. The broad part of the heart is so called, to distinguish it from the apex, or point.

Bassi co'lica. The name of a medicine in Scribonius Largus, compounded of aromatics and honey.

Bastard Pleurisy. See *Peripneumonia notha*.

Bata'tas. (So the natives of Peru call the potatoe, which is a native of that country, whence our word potatoe.) A species of night-shade, *solanum tuberosum*, Linn. which see.

BATH. (*Balneum, -i*, n. From βαλανεῖον, a bath.) Baths are of several kinds.

I. A convenient receptacle of water, for persons to wash or plunge in, either for health or pleasure, is called a bath. These are distinguished into hot and cold; and are either natural or artificial. The natural hot baths are formed of the water of hot springs, of which there are many in different parts of the world; especially in those countries where there are, or have evidently been, volcanoes. The artificial hot baths consist either of water, or of some other fluid, made hot by art. The cold bath consists of water, either fresh or salt, in its natural degree of heat; or it may be made colder by art, as by a mixture of nitre, sal-ammoniac, &c. The chief hot baths in our country are those of Bath and Bristol, and those of Buxton and Matlock; which latter, however, are rather warm, or tepid, than hot. The use of these baths is found to be beneficial in diseases of the head, as palsies, &c.; in cuticular diseases, as leprosies, &c.; obstructions and constipations of the bowels, the scurvy, and stone; and in many diseases of women and children. The cold bath, though popularly esteemed one of the most innocent remedies yet discovered, is not, however, to be adopted indiscriminately. On the contrary, it is liable to do considerable mischief in all cases of *diseased viscera*, and is not, in any case, proper to be used during the existence of costiveness. As a preventive remedy for the young, and as a general bracer for persons of a relaxed fibre, especially of the female sex, it often proves highly advantageous; and, in general, the popular idea is a correct one, that the *glow* which succeeds the use of cold or temperate baths, is a test of their utility; while, on the other hand, their producing *chilliness*, head-ache, &c. is a proof of their being pernicious.

The Cold Bath.

The diseases and morbid symptoms, for which the cold bath, under one form or another, may be applied with advantage, are very numerous; and some of them deserve particular attention. One of the most important of its uses is in *ardent fever*; and, under proper management, it forms a highly valuable remedy in this dangerous disorder. It is highly important, however, to attend to the precautions which the use of this vigorous remedial process requires. "Affusion with cold water," Dr. Currie observes, "may be used whenever the heat of the body is steadily above the natural standard, when there is no sense of chilliness, and especially when there is no general nor profuse perspiration. If used during the cold stage of a fever, even though the heat be higher than natural, it brings on interruption of respiration, a fluttering, weak, and extremely quick pulse, and certainly might be carried so far as to extinguish animation entirely." The most salutary consequence which follows the proper use of this powerful remedy, is the production of free and general perspiration. It is this circumstance that appears to give so much advantage to a general affusion of cold water in fevers, in preference to any partial application. The cold bath is better known, especially in this country, as a general tonic remedy in various chronic diseases. The general circumstances of disorder for which cold bathing appears to be of service, according to Dr. Saunders, are a languor and weakness of circulation, accompanied with profuse sweating and fatigue, on very moderate exertion; tremors in the limbs, and many of those symptoms usually called nervous; where the moving powers are weak, and the mind listless and indolent; but, at the same time, where no permanent morbid obstruction, or visceral disease, is present. Such a state of body is often the consequence of a long and debilitating sickness, or of a sedentary life, without using the exercise requisite to keep up the activity of the bodily powers. In all these cases, the great object to be fulfilled, is to produce a considerable re-action, from the shock of cold water, at the expense of as little heat as possible; and when cold-bathing does harm, it is precisely where the powers of the body are too languid to bring on re-action, and the chilling effects remain unopposed. When the patient feels the shock of immersion very severely, and, from experience of its pain, has acquired an insuperable dread of this application; when he has felt little or no friendly glow to succeed the first shock, but on coming out of the bath remains cold, shivering, sick at the stomach, oppressed with head-ache, languid, drowsy and listless, and averse to food and exercise during the whole of the day, we may be sure that the bath has been too cold, the shock too severe, and no re-action produced at all adequate to the impression on the surface of the body.

There is a kind of slow, irregular fever, or rather febricula, in which Dr. Saunders has often found the cold bath of singular service. This disorder principally affects persons naturally of a sound constitution, but who lead a sedentary life, and at the same time are employed in some occupation which strongly engages their attention, requires much exertion of thought, and excites a degree of anxiety. Such persons have constantly a pulse rather quicker than natural, hot hands, restless nights, and an impaired appetite, but without any considerable derangement in the digestive organs. This disorder will continue for a long time, in an irregular way, never entirely preventing their ordinary occupation, but rendering it more than usually anxious and fatiguing, and often preparing the way for confirmed hypochondriasis. Persons in this situation, are remarkably relieved by the cold-bath, and, for the most part, bear it well; and its use should also, if possible, be aided by that relaxation from business, and that diversion of the mind from its ordinary train of thinking, which are obtained by attending a watering place. The Doctor also found cold bathing hurtful in chlorosis, and observes, that it is seldom admissible in those cases of disease in the stomach which are brought on by high living, and constitute what may be termed the true dyspepsia.

The topical application of cold water, or of a cold saturnine lotion, in cases of local inflammation, has become an established practice; the efficacy of which is daily experienced. Burns of every description will bear a most liberal use of cold water, or even of ice; and this may be applied to a very extensive inflamed surface, without even producing the ordinary effects of general chilling, which would be brought on from the same application to a sound and healthy skin. Another very distressing symptom, remarkably relieved by cold water, topically applied, is that intolerable itching of the vagina, which women sometimes experience, entirely unconnected with any general cause, and which appears to be a kind of herpes confined to that part. Cold water has also been used topically in the various cases of strains, bruises, and similar injuries, in tendinous and ligamentous parts, with success; also in rigidity of muscles, that have been long kept at rest, in order to favour the union of bone, where there appears to have been no organic injury, but only a deficiency of nervous energy, and in mobility of parts, or at most, only slight adhesions, which would give way to regular exercise of the weakened limb. Another very striking instance of the powerful effects of topical cold, in stimulating a part to action, is shewn in the use of cold, or even iced water, to the vagina of parturient women, during the dangerous hemorrhages that take place from the uterus, on the partial separation of the placenta.

The Shower Bath.

A species of cold bath. A modern invention, in which the water falls, through numerous apertures, on the body. A proper apparatus for this purpose is to be obtained at the shops. The use of the shower bath applies, in every case, to the same purposes as the cold bath, and is often attended with particular advantages. 1. From the sudden contact of the water, which, in the common cold bath, is only momentary, but which, in the shower bath, may be prolonged, repeated, and modified, at pleasure; and, secondly, from the head and breast, which are exposed to some inconvenience and danger in the common bath, being here effectually secured, by receiving the first shock of the water.

The Tepid Bath.

The range of temperature, from the lowest degree of the hot bath to the highest of the cold bath, forms what may be termed the tepid. In general, the heat of water which we should term tepid, is about 90 deg. In a medicinal point of view, it produces the greatest effect in ardent fever, where the temperature is little above that of health, but the powers of the body weak, not able to bear the vigorous application of cold immersion. In cutaneous diseases, a tepid bath is often quite sufficient to produce a salutary relaxation, and perspirability of the skin.

The Hot Bath.

From 93 to 96 deg. of Fahrenheit, the hot bath has a peculiar tendency to bring on a state of repose, to alleviate any local irritation, and thereby induce sleep. It is, upon the whole, a safer remedy than the cold bath, and more peculiarly applicable to very weak and irritable constitutions, whom the shock produced by cold immersion would overpower, and who have not sufficient vigour of circulation for an adequate re-action. In cases of topical inflammation, connected with a phlogistic state of body, preceded by rigor and general fever, and where the local formation of matter is the solution of the general inflammatory symptoms, experience directs us to the use of the warm relaxing applications, rather than those which, by exciting a general re-action, would increase the local complaint. This object is particularly to be consulted when the part affected is one that is essential to life. Hence it is that in fever, where there is a great determination to the lungs, and the respiration appears to be locally affected, independently of the oppression produced by mere febrile increase of circulation, practitioners have avoided the external use of cold, in order to promote the solution of the fever; and have trusted to the general antiphlogistic treatment, along with the topically relaxing application of warm vapour, inhaled by the lungs. Warm bathing appears to be peculiarly well calculated to relieve those complaints that seem to depend on an irregular or diminished action of any part of the alimentary canal; and the state of the skin, produced by immersion in warm water, seems highly favourable to the healthy action of the stomach and bowels. Another very important use of the warm bath, is in herpetic eruptions, by relaxing the skin, and rendering it more pervious, and preparing it admirably for receiving the stimulant applications of tar ointment, mercurials, and the like, that are intended to restore it to a healthy state. The constitutions of children seem more extensively relieved by the warm bath than those of adults; and this remedy seems more generally applicable to acute fevers in them than in persons of a more advanced age. Where the warm bath produces its salutary operation, it is almost always followed by an easy and profound sleep. Dr. Saunders strongly recommends the use of the tepid bath, or even one of a higher temperature, in the true menorrhagia of females. In paralytic affections of particular parts, the powerful stimulus of heated water is generally allowed; and in these cases, the effect may be assisted by any thing which will increase the stimulating properties of the water, as, for instance, by the addition of salt. In these cases, much benefit may be expected from the use of warm sea-baths. The application of the warm bath topically, as in pediluvia, or fomentations to the feet, often produces the most powerful effects in quieting irritation in fever, and bringing on a sound and refreshing repose. The cases in which the warm bath is likely to be attended with danger, are particularly those where there exists a strong tendency to a determination of blood to the head; and apoplexy has sometimes been thus brought on. The lowest temperature will be required for cutaneous complaints, and to bring on relaxation in the skin, during febrile irritation; the warmer will be necessary in paralysis; more heat should be employed on a deep-seated part than one that is superficial.

The Vapour Bath.

The vapour bath, called also *Balneum laconicum,* though not much employed in England, forms a valuable remedy in a variety of cases. In most of the hot natural waters on the Continent, the vapour bath forms a regular part of the bathing apparatus, and is there highly valued. In no country, however, is this application carried to so great an extent as in Russia, where it forms the principal and almost daily luxury of all the people, in every rank; and it is employed as a sovereign remedy for a great variety of disorders. The Hon. Mr. Basil Cochrane has lately published a Treatise on the Vapour Bath, from which, it appears, he has brought the apparatus to such perfection, that he can apply it of all degrees of temperature, partially or generally, by shower, or by stream, with a great force or a small one; according to the particular circumstances under which patients are so variously placed, who require such assistance. See *Cochrane on Vapour Bath.* Connected with this article, is the *air-pump vapour-bath*; a species of vapour bath, or machine, to which the inventor has given this name. This apparatus has been found efficacious in removing paroxysms of the gout, and preventing their recurrence; in acute and chronic rheumatism, palsy, cutaneous diseases, ulcers, &c. It has also been proposed in chilblains, leprosy, yaws, tetanus, amenorrhea, and dropsy.

II. When the vessels in which bodies are exposed to the action of heat, are not placed in immediate contact with the fire, but receive the required degree of heat by another intermediate body, such apparatus is termed a bath. These have been variously named, as dry, vapour, &c. Modern chemists distinguish three kinds:

1. *Balneum arenæ*, or the sand bath. This consists merely of an open iron, or baked clay sand-pot, whose bottom is mostly convex, and exposed to the furnace. Finely sifted sea-sand is put into this, and the vessel containing the substance to be heated, &c. in the sand bath, immersed in the middle.

2. *Balneum mariæ*, or the water bath. This is very simple, and requires no particular apparatus. The object is, to place the vessel containing the substance to be heated, in another, containing water; which last must be of such a nature as to be fitted for the application of fire, as a common still, or kettle.

3. *The vapour bath.* When any substance is heated by the steam, or vapour, of boiling water, chemists say it is done by means of a vapour bath.

III. Those applications are called *dry baths*, which are made of ashes, salt, sand, &c. The antients had many ways of exciting a sweat, by means of a dry heat; as by the use of hot sand, stove rooms, or artificial bagnios; and even from certain natural hot steams of the earth, received under a proper arch, or hot-house, as we learn from Celsus. They had also another kind of bath by insolation, where the body was exposed to the sun for some time, in order to draw forth the superfluous moisture from the inward parts; and to this day it is a practice, in some nations, to cover the body over with horse-dung, especially in painful chronic diseases. In New England, they make a kind of stove of turf, wherein the sick are shut up to bathe, or sweat. It was probably from a knowledge of this practice, and of the exploded doctrines of Celsus, that the noted empiric Dr. Graham drew his notions of the salutary effects of what he called *earth bathing*; a practice which, in the way he used it, consigned some of his patients to a perpetual mansion under the ground. The like name of *dry* bath, is sometimes also given to another kind of bath, made of kindled coals, or burning spirit of wine. The patient being placed in a convenient close chair, for the reception of the fume, which rises and provokes sweat in a plentiful manner; care being taken to keep the head out, and to secure respiration. This bath has been said to be very effectual in removing old obstinate pains in the limbs.

IV. *Medicated baths* are such as are saturated with various mineral, vegetable, or sometimes animal substances. Thus we have sulphur and iron baths, aromatic and milk baths. There can be no doubt that such ingredients, if duly mixed, and a proper temperature given to the water, may, in certain complaints, be productive of effects highly beneficial. Water, impregnated with sulphate of iron, will abound with the bracing particles of that metal, and may be useful for strengthening the part to which it is applied, re-invigorating debilitated limbs, stopping various kinds of bleeding, restoring the menstrual and hemorrhoidal discharges when obstructed, and, in short, as a substitute for the natural iron bath. There are various other medicated baths, such as those prepared with alum and quick-lime, sal-ammoniac, &c. by boiling them together, or separately, in pure rain water. These have long been reputed as eminently serviceable in paralytic, and all other diseases arising from nervous and muscular debility.

BATH WATERS. *Bathoniæ aquæ. Solis aquæ. Badiguæ aquæ.* The city of Bath has been celebrated, for a long series of years, for its numerous hot springs, which are of a higher temperature than any in this kingdom, (from 112° to 116°,) and, indeed, are the only natural waters which we possess that are at all hot to the touch; all the other thermal waters being of a heat below the animal temperature, and only deserving that appellation from being invariably warmer than the general average of the heat of common springs. By the erection of elegant baths, these waters are particularly adapted to the benefit of invalids, who find here a variety of establishments, contributing equally to health, convenience, and amusement. There are three principal springs in the city of Bath, namely, those called the *King's Bath*, the *Cross Bath*, and the *Hot Bath*; all within a short distance of each other, and emptying themselves into the river Avon, after having passed through the several baths. Their supply is so copious, that all the large reservoirs used for bathing are filled every evening with fresh water, from their respective fountains. In their sensible and medicinal properties, there is but a slight difference. According to Dr. Falconer, the former are—1. That the water, when newly drawn, appears clear and colourless, remains perfectly inactive, without bubbles, or any sign of briskness, or effervescence. 2. After being exposed to the open air, for some hours, it becomes rather turbid, by the separation of a pale yellow, ochrey precipitate, which gradually subsides. 3. No odour is perceptible from a glass of the fresh water, but a slight pungency to the taste from a large mass of it, when fresh drawn; which, however, is neither fetid nor sulphureous. 4. When hot from the pump, it affects the mouth with a strong chalybeate impression, without being of a saline or pungent taste. And, fifthly, on growing cold, the chalybeate taste is entirely lost, leaving only a very slight sensation on the tongue, by which it can scarcely be distinguished from common hard spring-water. The temperature of the King's Bath water, which is usually preferred for drinking, is, when fresh drawn in the glass, above 116 deg.; that of the Cross Bath, 112 deg. But, after flowing into the spacious bathing vessels, it is generally from 100 to 106 deg. in the hotter baths, and from 92 to 94 deg. in the Cross Bath; a temperature which remains nearly stationary, and is greater than that of any other natural spring in Britain. A small quantity of gas is also disengaged from these waters, which Dr. Priestley first discovered to contain no more than one-twentieth part of its bulk of fixed air, or carbonic acid. The chemical properties of the Bath waters, according to the most accurate analysers, Doctors Lucas, Falconer, and Gibbs, contain so small a proportion of iron, as to amount only to one-twentieth or one-thirty-eighth of a grain in the pint; and, according to Dr. Gibbs, fifteen grains and a quarter of siliceous earth in the gallon. Dr. Saunders estimates a gallon of the King's Bath water to contain about eight cubic inches of carbonic acid, and a similar quantity of air, nearly azotic, about eighty grains of solid ingredients, one-half of which probably consists of sulphate and muriate of soda, fifteen grains and a half of siliceous earth, and the remainder is selenite, carbonate of lime, and so small a portion of oxide of iron as to be scarcely calculable. Hence he concludes, that the King's Bath water is the strongest chalybeate; next in order, the Hot Bath water; and lastly, that of the Cross Bath, which contains the smallest proportions of chalybeate, gaseous and saline, but considerably more of the earthy particles; while its water, in the pump, is also two degrees lower than that of the others. It is likewise now ascertained, that these springs do not exhibit the slightest traces of sulphur, though it was formerly believed, and erroneously supported on the authority of Dr. Charleton, that the subtile aromatic vapour in the Bath waters, was a sulphureous principle, entirely similar to common brimstone.

With regard to the effect of the Bath waters on the human system, independent of their specific properties, as a medicinal remedy not to be imitated completely by any chemical process, Dr. Saunders attributes much of their salubrious influence to the natural degree of warmth peculiar to these springs, which, for ages, have preserved an admirable degree of uniformity of temperature. He thinks too, that one of their most important uses is that of an external application, yet supposes that, in this respect, they differ little from common water, when heated to the same temperature, and applied under similar circumstances.

According to Dr. Falconer, the Bath water, when drunk fresh from the spring, generally raises, or rather accelerates the pulse, increases the heat, and promotes the different secretions. These symptoms in most cases, become perceptible soon after drinking it, and will sometimes continue for a considerable time. It is, however, remarkable, that they are only produced in invalids. Hence we may conclude, that these waters not only possess heating properties, but their internal use is likewise attended with a peculiar stimulus, acting more immediately on the nerves.

One of the most salutary effects of the Bath water, consists in its action on the urinary organs, even when taken in moderate doses. Its operation on the bowels varies in different individuals, like that of all other waters, which do not contain any cathartic salt; but, in general, it is productive of costiveness: an effect resulting from the want of an active stimulus to the intestines, and probably also from the determination this water occasions to the skin, more than from any astringency which it may possess; for, if perspiration be suddenly checked during the use of it, a diarrhœa is sometimes the consequence. Hence it appears that its stimulant powers are primarily, and more particularly exerted in the stomach, where it produces a variety of symptoms, sometimes slight and transient, but, occasionally, so considerable and permanent, as to require it to be discontinued. In those individuals with whom it is likely to agree, and prove beneficial, the Bath waters excite, at first, on agreeable glowing sensation in the stomach, which is speedily followed by an increase both of appetite and spirits, as well as a quick secretion of urine. In others, when the use of them is attended with head-ache, thirst, and constant dryness of the tongue, heaviness, loathing of the stomach, and sickness; or if they are not evacuated, either by urine or an increased perspiration, it may be justly inferred that their further continuance is improper.

The diseases for which these celebrated waters are resorted to, are very numerous, and are some of the most important and difficult of cure of all that come under medical treatment. In most of them, the bath is used along with the waters, as an internal medicine. The general indications, of the propriety of using this medicinal water, are in those cases where a gentle, gradual, and permanent stimulus, is required. Bath water may certainly be considered as a chalybeate, in which the iron is very small in quantity, but in a highly active form; and the degree of temperature is in itself a stimulus, often of considerable powers. These circumstances again point out the necessity of certain cautions, which, from a view of the mere quantity of foreign contents, might be thought superfluous. Although, in estimating the powers of this medicine, allowance must be made for local prejudice in its favour, there can be no doubt but that its employment is hazardous, and might often do considerable mischief, in various cases of active inflammation, especially in irritable habits, where there exists a strong tendency to hectic fever; and even in the less inflammatory state of diseased and suppurating viscera; and, in general, wherever a quick pulse and dry tongue indicate a degree of general fever. The cases, therefore, to which this water are peculiarly suited, are mostly of the chronic kind; and by a steady perseverance in this remedy, very obstinate disorders have given way. The following, Dr. Saunders, in his Treatise on Mineral Waters, considers as the principal, viz. 1. Chlorosis, a disease which, at all times, is much relieved by steel, and will bear it, even where there is a considerable degree of feverish irritation, receives particular benefit from the Bath water; and its use, as a warm bath, excellently contributes to remove that languor of circulation, and obstruction of the natural evacuations, which constitute the leading features of this common and troublesome disorder. 2. The complicated diseases, which are often brought on by a long residence in hot climates, affecting the secretion of bile, the functions of the stomach, and alimentary canal, and which generally produce organic derangement in some part of the hepatic system, often receive much benefit from the Bath water, if used at a time when suppurative inflammation is not actually present. 3. Another and less active disease of the biliary organs, the jaundice, which arises from a simple obstruction of the gall-ducts, is still oftener removed by both the internal and external use of these waters. 4. In rheumatic complaints, the power of this water, as Dr. Charleton well observes, is chiefly confined to that species of rheumatism which is unattended with inflammation, or in which the patient's pains are not increased by the warmth of his bed. A great number of the patients that resort to Bath, especially those that are admitted into the hospital, are affected with rheumatism in all its stages; and it appears, from the most respectable testimony, that a large proportion of them receive a permanent cure. (See *Falconer on Bath Water in Rheumatic Cases.*) 5. In gout, the greatest benefit is derived from this water, in those cases where it produces anomalous affections of the head, stomach, and bowels; and it is here a principal advantage to be able to bring, by warmth, that active local inflammation in any limb, which relieves all the other troublesome and dangerous symptoms. Hence it is that Bath water is commonly said to produce the gout; by which is only meant that, where persons have a gouty affection, shifting from place to place, and thereby much disordering the system, the internal and external use of the Bath water will soon bring on a general increase of action, indicated by a flushing in the face, fulness in the circulating vessels, and relief of the dyspeptic symptoms; and the whole disorder will terminate in a regular fit of the gout in the extremities, which is the crisis always to be wished for. 6. The colica pictonum, and the paralysis, or loss of nervous power in particular limbs, which is one of its most serious consequences, is found to be peculiarly relieved by the use of the Bath waters, more especially when applied externally, either generally, or upon the part affected.

The quantity of water taken daily, during a full course, and by adults, is recommended by Dr. Falconer, not to exceed a pint and a half, or two pints; and in chlorosis, with irritable habits, not more than one pint is employed; and when the bath is made use of, it is generally two or three times a week, in the morning. The Bath waters require a considerable time to be persevered in, before a full and fair trial can be made. Chronic rheumatism, habitual gout, dyspepsia, from a long course of high and intemperate living, and the like, are disorders not to be removed by a short course of any mineral water, and many of those who have once received benefit at the fountains, find it necessary to make an annual visit to them, to repair the waste in health during the preceding year.

BATH, CAUTERES. A sulphureous bath near Barege, which raises the mercury in Fahrenheit's thermometer to 131 deg.

BATH, ST. SAUVEUR'S. A sulphureous and alkaline bath, in the valley adjoining Barege, the latter of which raises Fahrenheit's thermometer as high as 131 deg. It is much resorted to from the South of France, and used chiefly externally, as a simple thermal water.

Bath, cold. See *Bath.*

Bath, vapour. See *Bath.*

Bath, tepid. See *Bath.*

Bath, hot. See *Bath.*

Ba′thmis. (From βαινω, to enter.) *Bathmus.* The seat, or base; the cavity of a bone, with the protuberance of another, particularly those at the articulation of the humerus and ulna, according to Hippocrates and Galen.

Batho'niæ a'quæ. Bath waters.

Ba'thron. (From βαινω, to enter.) *Bathrum.* The same as bathmis; also an instrument used in the extension of fractured limbs, called scamnum. *Hippocrates.* It is described by Oribasius and Scultetus.

Ba'tia. A name formerly given to a retort.

Bati'non-mo'ron. (From βατος, a bramble, and μορον, a raspberry.) A raspberry.

Batra'chium. (From βατραχος, a frog; so called from its likeness to a frog.) The herb crow's foot, or ranunculus.

Ba'trachus. (From βατραχος, a frog; so called because they who are infected with it croak like a frog.) An inflammatory tumour under the tongue.

Battari'smus. (From Βαττος, a Cyrenæan prince, who stammered.) Stammering; a defect in pronunciation. See *Psellismus.*

Batta'ta Virginia'na. See *Solanum tuberosum.*

Batta'ta peregri'na. The cathartic potatoe; perhaps a species of *ipomœa.* If about two ounces of them are eaten at bedtime, they greatly move the belly the next morning.

BATTIE, William, was born in Devonshire, in 1704. He graduated at Cambridge, and after practising some years successfully at Uxbridge, settled in London, and became a fellow of the College of Physicians, as well as of the Royal Society. The insufficiency of Bethlehem hospital to receive all the indigent objects labouring under insanity in this metropolis, naturally led to the establishment of another similar institution; and Dr. Battie having been very active in promoting the subscription for that purpose, he was appointed physician to the new institution, which was called St. Luke's Hospital, then situated on the north side of Moorfields. In 1757 he published a treatise on madness; and a few years after, having exposed before the House of Commons the abuses often committed in private madhouses, they became the subject of legislative interference, and were at length placed under the controul of the College of Physicians, and the magistrates in the country. He died at the age of 72.

Bau'da. A vessel for distillation was formerly so called.

BAUHIN, John, was born at Lyons, in 1541. Being greatly attached to botany, he accompanied the celebrated Gesner in his travels through several countries of Europe, and collected abundant materials for his principal work, the "Historia Plantarum," which contributed greatly to the improvement of his favourite science. He was, at the age of 32, appointed physician to the duke of Wirtemberg, and died in 1613. A Treatise on Mineral Waters, and some other publications by him also remain.

BAUHIN, Gaspard, was brother to the preceding, but younger by 20 years. He graduated at Basle, after studying at several universities, and was chosen Greek professor at the early age of 22; afterwards professor of anatomy and botany; then of medicine, with other distinguished honours, which he retained till his death in 1624. Besides the plants collected by himself, he received material assistance from his pupils and friends, and was enabled to add considerably to the knowledge of botany; on which subject, as well as anatomy, he has left numerous publications. Among other anatomical improvements, he claims the discovery of the valve of the colon. His "Pinax" contains the names of six thousand plants mentioned by the antients, tolerably well arranged; and being continually referred to by Linnæus, must long retain its value.

Baulmoney. See *Æthusa meum.*

BAUMÈ, Anthony, an apothecary, born at Senlis in 1728. He distinguished himself at an early age by his skill in chemistry and pharmacy: and was afterwards admitted a member of the Royal Academy of Sciences of Paris. He also gave lectures on chemistry for several years with great credit. Among other works, he published "Elements of Pharmacy," and a "Manual of Chemistry," which met with considerable approbation: also a detailed account of the different kinds of soil, and the method of improving them for the purposes of agriculture.

Bau'rach. (Arab. *Bourach.*) A name formerly applied to nitre, or any salt; hence it is that borax took its name, which is also thus called, as well as the mineral fixed alkaline salt.

Baxa'na. (Indian.) A poisonous tree growing near Ormuz; called by Ray, rabuxit.

Bay-cherry. See *Prunus Lauro-cerasus.*

Bay-leaves. See *Laurus.*

Bay-leaved Passion-flower. The plant so called is the *Passiflora laurifolia* of Linnæus: which see.

Bay-salt. A very pure salt, prepared from sea-water by spontaneous evaporation.

Ba'zcher. A Persian word for antidote.

Bde'lla. (From βδαλλω, to suck.) *Bdellerum.* A horse-leech.

BDE'LLIUM. (From *bedallah.* Arab.) *Madeleon. Bolchon. Balchus.* Called by the Arabians, mokel. A gum, like very impure myrrh. It is one of the weakest of the deobstruent gums. It was sometimes used as a pectoral and an emmenagogue. Applied externally, it is stimulant, and promotes suppuration. It is never met with in the shops of this country.

Bde'llus. (From βδεω, to break wind.) A discharge of wind by the anus.

Bdely'gmia. (From βδεω, to break wind.) Any filthy and nauseous odour.

Bean. The common bean is the seed of the *Vicia faba* of Linnæus: which see.

Bean, French.
Bean, Kidney. } See *Phaseolus vulgaris.*

Bean, Malacca. See *Avicennia tomentosa.*

Bean of Carthagena. See *Bejuio.*

Bean, St. Ignatius. See *Ignatia amara.*

Beard. The hair growing on the chin and adjacent parts of the face, in adults of the male sex.

Bear's-breech. See *Acanthus.*

Bear's-foot. See *Helleborus fœtidus.*

Bear's-whortleberry. See *Arbutus uva ursi.*

Be'cca. A fine kind of resin from the turpentine and mastich trees of Greece and Syria, formerly held in great repute.

BECCABU'NGA. (From *bach bungen*, water-herb, German, because it grows in rivulets.) See *Veronica.*

Be'cha. See *Bechica.*

Be'chica. (From βηξ, a cough.) *Bechita.* Medicines to relieve a cough. An obsolete term. The *trochisci bechici albi* consist of starch and liquorice, with a small proportion of florentine orris root made into lozenges, with mucilage of gum-tragacanth. They are a soft pleasant demulcent. The *trochisci bechici nigri* consist chiefly of the juice of liquorice, with sugar and gum-tragacanth.

Be'chion. (From βηξ, a cough; so called from its supposed virtues in relieving coughs.) *Bechium.* The herb colt's-foot, or tussilago.

Becui'ba nux. (Indian.) A large nut growing in Brasil, from which a balsam is drawn that is held in estimation in rheumatisms.

Bede'guar. (Arab.) *Bedeguar.* The Carduus lacteus Syriacus is so called, and also the cynosbatos, or rosa canina.

Bedengian. The name of the love-apples in Avicenna.

Bedstraw, lady's. See *Galium Aparine.*

BEE. *Apis mellifica* of Linnæus. This insect was formerly exhibited, after being dried and powdered, internally, as a diuretic. It is to the industry of bees we are indebted for those valuable articles, honey and wax. See *Honey* and *Cera.*

Beech tree. See *Fagus.*

BEES' WAX. See *Cera.*

Beet, red. See *Beta.*

Beet, white. A variety of red beet. The juice and powder of the root are good to excite sneezing, and will bring away a considerable quantity of mucus.

Be'gma. (From βησσω, to cough.) A cough. Expectorated mucus, according to Hippocrates.

Be'hen a'lbum. (From *behen*, a finger, Arab.). See *Centaurea behen.*

Be'hen officina'rum. See *Cucubalus behen.*

Be'hen ru'brum. See *Statice Limonium.*

Beide'lsar. *Beidellopar.* A species of Asclepias, used in Africa as a remedy for fever and the bites of serpents. The caustic juice which issues from the roots when wounded, is used by the negroes to destroy venereal and similar swellings.

Beju'io. *Habilla de Carthagenâ.* Bean of Carthagena. A kind of bean in South America, famed for being an effectual antidote against the poison of all serpents, if a small quantity is eaten immediately. This bean is the peculiar product of the jurisdiction of Carthagena.

Bela-aye co'rtex. (Indian.) *Belae.* A bark of Madagascar, said to be of considerable efficacy in the cure of diarrhœas.

Belemnoi'des. (From βελεμνον, a dart, and ειδος, form; so named from their dart-like shape.) *Belenoides. Beloidos.* The styloid process of the temporal bone, and the lower end of the ulna, were formerly so called.

Bele'son. (Indian.) *Belilia.* The *Mussenda frondosa* of Linnæus, a decoction of which is, according to Ray, cooling.

BELLADO'NNA. (From *bella donna*, Italian, a handsome lady; so called because the ladies of Italy use it, to take away the too florid colour of their faces.) See *Atropa belladonna.*

Be'llegu.
Bellere'gi.
Be'lnileg.
Belle'ricæ. } See *Myrobalanus Bellirica.*

Bellidioi'des. (From *bellis*, a daisy, and ειδος, form.) See *Chrysanthemum.*

BELLI'NI, Laurence, an ingenious physician, born at Florence in 1643. He was greatly attached to the mathematics, of which he was made professor at Pisa, when only twenty years of age. He was soon after appointed professor of anatomy, which office he filled with credit for nearly thirty years. He was one of the chief supporters of the mathematical theory of medicine, which attempted to explain the functions of the body, the causes of diseases, and the operations of medicines on mechanical principles: and having imprudently regulated his practice accordingly, he was generally unsuccessful, and lost the confidence of the public, as well as of Cosmo III. of Florence, who had appointed him his physician. In his anatomical researches he was more successful, having first accurately described the nervous papillæ of the tongue, and discovered them to be the organ of taste; and also having made better known the structure of the kidney. He was the author of several other publications, and died in 1704.

BE'LLIS. (*à bello colore*, from its fair colour.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia superflua.* The daisy.

Be'llis ma'jor. See *Chrysanthemum.*

Be'llis mi'nor. See *Bellis perennis.*

Be'llis pere'nnis. The systematic name

of the common daisy. *Bellis. Bellis minor.* The *bellis perennis* of Linnæus: — *scapo nudo,* or bruisewort, was formerly directed in pharmacopœias by this name. Although the leaves and flowers are rather acrid, and are said to cure several species of wounds, they are never employed by modern surgeons.

Bello′culus. (From *bellus,* fair, and *oculus,* the eye.) A precious stone, resembling the eye, and formerly supposed to be useful in its disorders.

Be′llon. The Devonshire colic, or colica pictonum.

Bellona′ria. (From *Bellona,* the goddess of war.) A herb which, if eaten, makes people mad, and act outrageously, like the votaries of Bellona.

BELLOSTE, Augustin, a surgeon, born at Paris in 1654. After practising several years there, and as an army surgeon, he was invited to attend the mother of the Queen of Sardinia, and continued at Turin till his death in 1730. He was inventor of a mercurial pill, called by his name, by which he is said to have acquired a great fortune. The work by which he is principally known, is called the "Hospital Surgeon," which passed through numerous editions, and was translated into most of the European languages. Among other useful observations, he recommended piercing carious bones, to promote exfoliation, which indeed Celsus had advised before; and he blamed the custom of frequently changing the dressings of wounds, as retarding the cure.

Bellu′tta Tsja′mpacam. (Indian.) A tree of Malabar, to which many virtues are attributed.

Belmu′schus. A name given to the Abelmoschus.

Belo′ere. (Indian.) An evergreen plant of America, whose seeds purge moderately, but the leaves roughly.

Belonoi′des. *Beloides.* The same as belemnoides.

Belu′lcum. (From βελος, a dart, and ελκω, to draw out.) A surgeon's instrument for extracting thorns, or darts.

Belu′zzar. *Beluzaar.* The Chaldee word for antidote.

Belzo′e. } See *Styrax Benzoin.*
Belzoi′num. }

Bemcurini. An Indian shrub used in gout.

Bem-ta′mara. (Arab.) The faba Ægyptiaca.

Ben. (Arab.) See *Guilandina moringa.*

Ben ma′gnum. Monardus calls by this name, the avellana purgatrix, which purges and vomits violently.

Ben ta′mara. The Egyptian bean.

Be′nath. (Arab.) Small pustules produced by sweating in the night.

Be′nedict. (From *benedico,* to bless.) A specific name prefixed to many compositions and herbs on account of their supposed good qualities; as benedicta herba, benedicta aqua, &c.

Benedi′cta a′qua. Lime-water was formerly so called: also a water distilled from serpyllum, and, in Schroeder, it is the name for an emetic.

Benedi′cta a′qua compo′sita. Compound lime-water.

Benedi′cta he′rba. See *Geum urbanum.*

Benedi′cta laxati′va. A compound of turbeth, scammony, and spurges, with some warm aromatics.

Benedi′ctum laxati′vum. Rhubarb, and sometimes the lenitive electuary.

Benedi′ctum li′gnum. A term applied to Guaiacum.

Benedi′ctum vi′num. Antimonial wine.

Benedi′ctus ca′rduus. See *Centaurea benedicta.*

Benedi′ctus la′pis. A name for the philosopher's stone.

Beneole′ntia. (From *bene,* well, and *oleo,* to smell.) Sweet-scented medicines, as gums, &c.

Beng. A name given by the Mahomedans to the leaves of hemp, formed into pills, or conserve. They possess exhilarating and intoxicating powers.

Benga′læ ra′dix. (From *Bengal,* its native place.) See *Cassumuniar.*

Benga′l quince. This fruit is the produce of the *Erateva marmelos* of Linnæus; which see.

Benga′lle Indo′rum. (From *Bengal,* its native place.) See *Cassumuniar.*

Be′ngi ei′ri. A species of evergreen, Indian ricinus, which grows in Malabar.

Benit herb. See *Geum urbanum.*

Beni′vi a′rbor. See *Styrax benzoin.*

Benjamin. See *Styrax benzoin.*

Benjamin flowers. See *Benzoic acid.*

BENZO′AS. A benzoate. A salt formed by the union of benzoic acid, with an alkaline, earthy, or metallic base; as benzoate of alumine, &c.

Benzo′e. See *Styrax benzoin.*

Benzo′e amygdaloi′des. See *Styrax benzoin.*

BENZO′IC ACID. *Acidum benzoicum. Flores benzoes. Flores benzoini.* Benjamin flowers. This acid exists in several balsams, but principally in the concrete balsam, called benzoin. (See *Styrax benzoin.*) Chemists have obtained it from this balsam in various ways, either by sublimation, which gives beautiful foliated crystals, but the process requires to be repeated thrice, and the crystals pressed between bibulous paper after each sublimation, to obtain them white and free from any adherent essential oil: or, by forming some of its soluble compounds, and afterwards decomposing them, so as to precipitate the acid; or, by simply boiling the benzoin in water, which dissolves the acid, and, as it cools, allows it to separate again. The London Pharmacopœia directs it to be obtained thus: — "Take of benzoin, a pound and a half: fresh lime, four ounces: water, a gallon and a half: muriatic acid, four fluid ounces. Rub together the benzoin and lime; then boil them in a gallon of the water, for half an hour, constantly stirring; and, when it is cold, pour off the liquor. Boil what remains, a second time, in four pints of water, and pour off the liquor as before. Mix the liquors, and boil down to half, then strain through paper, and add the muriatic acid gradually, until it ceases to produce a precipitate. Lastly, having poured off the liquor, dry the powder in a gentle heat; put it into a proper vessel, placed in a sand bath; and, by a very gentle fire, sublime the benzoic acid." In this process a solution of benzoate of lime is first obtained, by boiling the benzoin and lime in water; the muriatic acid then abstracting the lime precipitates the benzoic acid, which is finally crystallized by sublimation.

The Edinburgh Pharmacopœia forms a benzoate of soda, precipitates the acid by sulphuric acid, and afterwards crystallizes it by solution in hot water, which dissolves a larger quantity than cold.

Benzoic acid has a strong, pungent, aromatic, and peculiar odour. Its crystals are ductile, not pulverizable; it sublimes in a moderate heat, forming a white irritating smoke. It is soluble in about twenty-four times its weight of boiling water, which, as it cools, precipitates 19-20ths of what it had previously dissolved. It is soluble in alkohol.

Benzoic acid is very seldom used in the cure of diseases; but now and then it is ordered as a stimulant against convulsive coughs and difficulty of breathing. The dose is from one grain to five.

It combines with alkaline, metallic, and earthy bodies; and forms benzoates.

Benzoi′fera. See *Styrax benzoin.*

BENZO′INUM. (From the Arabic term *benzoah.*) See *Styrax benzoin.*

Benzo′es flo′res. See *Benzoic acid.*

Benzo′ini magiste′rium. Magistery or precipitate of gum-benjamin.

Benzo′ini o′leum. Oil of benjamin.

BE′RBERIS. (*Berberi,* wild. Arab. used by Averrhoes, and officinal writers.)

1. The name of a genus of plants in the Linnæan system. Class, *Hexandria.* Order, *Monogynia.* The barberry, or pepperidge bush.

2. The pharmacopœial name for the barberry. See *Berberis vulgaris.*

Be′rberis gelati′na. Barberries boiled in sugar.

Be′rberis vulga′ris. The systematic name for the barberry of the pharmacopœias. *Oxycantha Galeni. Spina acida. Crespinus.* This tree, *Berberis pedunculis racemosis, spinis triplicibus,* of Linnæus, is a native of England. The fruit, or berries, which are gratefully acid, and moderately adstringent, are said to be of great use in biliary fluxes, and in all cases where heat, acrimony, and putridity of the humours prevail. The filaments of this shrub possess a remarkable degree of irritability; for on being touched near the base with the point of a pin, a sudden contraction is produced, which may be repeated several times.

Bere′drias. An ointment.

BERENGA′RIUS, James, born about the end of the 15th century at Carpi, in Modena, whence he is often called *Carpus.* He was one of the restorers of anatomy, of which he was professor, first at Padua, afterwards at Bologna, which he was in a few years obliged to quit, being accused of having opened the bodies of two Spaniards alive. By his numerous dissections, he corrected many previous errors concerning the structure of the human body, and paved the way for his successor Vesalius. He was among the first to use mercurial frictions in syphilis, whereby he acquired a large fortune, which he left to the Duke of Ferrara, into whose territory he retired at his death in 1527. His principal works are an enlarged Commentary on Mundinus, and a Treatise on Fracture of the Cranium.

Bereni′ce. (The city from whence it was formerly brought.) Amber.

Bereni′cium. (From φερω, to bring, and νικη, victory.) A term applied by the old Greek writers to nitre, from its supposed power in healing wounds.

Bereni secum. Mugwort. See *Artemisia vulgaris.*

BERGAMO′TE. A species of citron. See *Citrus.*

Beribe′ri. (An Hindostane word signifying a sheep.) *Beriberia.* A species of palsy, common in some parts of the East Indies, according to Bontius. In this disease, the patients lift up their legs very much in the same manner as is usual with sheep. Bontius adds, that this palsy is a kind of trembling, in which there is deprivation of the motion and sensation of the hands and feet, and sometimes of the body.

BERKENHOUT, John, born at Leeds, about the year 1730. His medical studies were commenced late in life, having graduated at Leyden only in 1765; nor did he long continue the practice of medicine. His "Pharmacopœia Medica," however, was very much approved, and has since passed through many editions: his other medical publications are of little importance. He died in 1791.

Bermudas berry. See *Sapindus Saponaria.*

Berna′rvi. An electuary.

Berrio′nis. A name for colophony, or black rosin.

Bers. Formerly the name of an exhilarating electuary.

Be′rula. An old name for brooklime.

Be′rula ga′llica. Upright water parsnep.

Bery′tion. (From *Berytius*, its inventor.) A collyrium described by Galen.

Bes. An eight-ounce measure.

Be′sachar. An obsolete term for a sponge.

Be′sasa. Formerly applied to wild rue.

Besbase. An old name for mace.

Bese′nna. (Arab.) *Muscarum Fungus.* Probably a sponge, which is the nidus of some sorts of flies.

Bessa′nen. (Arab.) A redness of the external parts, resembling that which precedes the leprosy; it occupies the face and extremities. *Avicenna.*

Be′sto. A name in Oribasius for *Saxifrage.*

BE′TA. (So called from the river *Bætis*, in Spain, where it grows naturally; or, according to Blanchard, from the Greek letter βητα, which it is said to resemble when turgid with seed.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.* The beet.

2. The pharmacopœial name of the common beet. See *Beta vulgaris.*

Be′ta vulga′ris. The systematic name for the beet of the pharmacopœias. *Beta floribus congestis* of Linnæus. The root of this plant is frequently eaten by the French; it may be considered as nutritious and antiscorbutic, and forms a very elegant pickle with vinegar. The root and leaves, although formerly employed as laxatives and emollients, are now forgotten. A considerable quantity of sugar may be obtained from the root of the beet. It is likewise said, that if beet roots be dried in the same manner as malt, after the greater part of their juice is pressed out, very good beer may be made from them. It is occasionally used to improve the colour of claret.

Betele. *Bethle. Betle. Betelle.* An oriental plant, like the tail of a lizard. It is chewed by the Indians, and makes the teeth black; is cordial and exhilarating, and in very general use throughout the East. It is supposed to be the long pepper.

BETO′NICA. (Corrupted from *Vettonica*, which is derived from the *Veetones*, an antient people of Spain.) Betony.

1. The name of a genus of plants in the Linnæan system. Class, *Didynamia.* Order, *Gymnospermia.*

2. The pharmacopœial name for the wood betony. See *Betonica officinalis.*

Beto′nica aqua′tica. See *Scrophularia aquatica.*

Beto′nica officina′lis. The systematic name of the betony of the pharmacopœias. *Betonica purpurea. Vetonica cordi. Betonica spica interrupta, corollarum labii lacinia intermedia emarginata* of Linnæus. The leaves and tops of this plant have an agreeable, but weak smell; and to the taste they discover a slight warmth, accompanied with some degree of adstringency and bitterness. The powder of the leaves of betony, snuffed up the nose, provokes sneezing; and hence it is sometimes made an ingredient in sternutatory powders. Its leaves are sometimes smoked like tobacco. The roots differ greatly, in their quality, from the other parts; their taste is very bitter and nauseous; taken in a small dose, they vomit and purge violently, and are supposed to have somewhat in common with the roots of helebore. Like many other plants, formerly in high medical estimation, betony is now almost entirely neglected. Antonius Musa, physician to the Emperor Augustus, filled a whole volume with enumerating its virtues, stating it as a remedy for no less than forty-seven disorders; and hence in Italy the proverbial compliment, *You have more virtues than betony.*

Beto′nica pau′li. A species of veronica.

Beto′nica vulga′ris. The *betonica officinalis* is so called in some pharmacopœias.

Betony, water. See *Scrophularia aquatica.*

BE′TULA. 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia.* Order, *Tetrandria.* Alder and birch.

2. The pharmacopœial name of the white birch. See *Betula alba.*

Be′tula a′lba. The systematic name for the *betula* of the pharmacopœias. *Betula alba, foliis ovatis, acuminatis, serratis,* of Linnæus. The juice, leaves, and bark have been employed medicinally. If the tree be bored early in the spring, there issues, by degrees, a large quantity of limpid, watery, sweetish juice: it is said that one tree will afford from one to two gallons a-day. This juice is esteemed as an antiscorbutic, deobstruent, and diuretic. The leaves and bark are used externally as resolvents, detergents, and antiseptics.

Be′tula a′lnus. The systematic name for the *alnus* of the pharmacopœias. The common alder, called *Amendanus:* for an account of its virtues, see *Rhamnus frangula.*

Bex. (From βησσω, to cough.) A cough.

Bexu′go. The root of the *Æmatitis Peruviana* of Casper Bauhin; one drachm of which is sufficient for a purge.

Bexagui′llo. A name given to the white ipecacuanha, which the Spaniards bring from Peru, as the Portuguese do the brown from Brazil.

Be′zahan. The fossile bezoar.

Beze′tta cœru′lea. See *Croton tinctorium.*

BE′ZOAR. (From *pa-zahar*, Persian, a destroyer of poison.) *Lapis bezoardicus.* Bezoard. A preternatural or morbid concretion formed in the bodies of land-animals. Several of these kinds of substances were formerly celebrated for their medicinal virtues, and distinguished by the names of the countries from whence they came, or the animal in which they were found. They were considered as powerful alexipharmics, in so much so, that other medicines, possessed, or supposed to be possessed of alexipharmic powers, were called *bezoardics*; and so efficacious were they once thought, that they were bought for ten times their weight in gold. These virtues, however, are in the present day justly denied them, as they produce no other effects than those common to the saline particles which they contain, and which may be given to greater advantage from other sources. A composition of bezoar with absorbent powders, has been much in repute, as a popular remedy for disorders in children, by the name of Gascoigne's powder and Gascoigne's ball; but the real bezoar was rarely, if ever, used for these, its price offering such a temptation to counterfeit it. Some have employed for this purpose, a resinous composition, capable of melting in the fire and soluble in alkohol; but Newmann supposed that those nearest resembling it, were made of gypsum, chalk, or some other earth, to which the proper colour was imparted by some vegetable juice. We understand, however, that tobacco-pipe clay, tinged with ox-gall, is commonly employed, at least for the Gascoigne's powder; this giving a yellow tint to paper, rubbed with chalk, and a green to paper rubbed over with quicklime; which are considered as proofs of genuine bezoar, and which a vegetable juice would not effect.

Be′zoar bovi′num. The bezoar from the ox.

Be′zoar Germa′nicum. The bezoar from the alpine goat.

Be′zoar hy′stricis. *Lapis porcinus. Lapis malacensis. Petro del porco.* The bezoar of the Indian porcupine. Said to be found in the gall-bladder of an Indian porcupine, particularly in the province of Malacca. This concrete differs from others; it has an intensely bitter taste; and on being steeped in water for a very little time, impregnates the fluid with its bitterness, and with aperient, stomachic, and, as it is supposed, with alexipharmic virtues. How far it differs in virtue from the similar concretions found in the gall-bladder of the ox, and other animals, does not appear.

Be′zoar occidenta′le. Occidental bezoar. This concretion is said to be found in the stomach of an animal of the stag or goat kind, a native of Peru, &c. It is of a larger size than the oriental bezoar, and sometimes as large as a hen's egg; its surface is rough, and the colour green, greyish, or brown.

Be′zoar orienta′le. *Lapis bezoar orientalis.* Oriental bezoar stone. This concretion is said to be found in the pylorus, or fourth stomach of an animal of the goat kind, which inhabits the mountains of Persia. It is generally about the size of a kidney bean, of a roundish or oblong figure, smooth, and of a shining olive or dark greenish colour.

Be′zoar microco′smicum. The calculus found in the human bladder.

Be′zoar porci′num. See *Bezoar hystricis.*

Be′zoar si′miæ. The bezoar of the monkey.

Bezoa′rdica ra′dix. See *Dorstenia.*

Bezoa′rdicum jovia′le. *Bezoar* with tin. It differed very little from the *Antihecticum Poterii.*

Bezoa′rdicum luna′le. A preparation of antimony and silver.

Bezoa′rdicum martia′le. A preparation of iron and antimony.

Bezoa′rdicum minera′le. A preparation of antimony, made by adding nitrous acid to butter of antimony.

Bezoa′rdicum satu′rni. A preparation of antimony and lead.

Bezoa′rdicus pu′lvis. The powder of the oriental bezoar.

Bezoa′rticum minera′le. An inert calx of antimony.

Bezoa′rticus spi′ritus ni′tri. The distilled acid of the bezoarticum minerale.

Bezoas. A common chemical epithet.

Biæ′on. Wine of sun-raisins and sea-water.

Bibine′lla. See *Pimpinella.*

Bibito′rius. (*Bibitorius*, sc. *musculus*; from *bibo*, to drink; because by drawing the eye inwards towards the nose, it causes those who drink to look into the cup.) See *Rectus internus oculi.*

BI′CEPS. (From *bis*, twice, and *caput*, a head.) Many muscles have this denomination, from their having two distinct heads, or origins.

Bi′ceps bra′chii. See *Biceps flexor cubiti.*

Bi′ceps cru′ris. See *Biceps flexor cruris.*

Bi′ceps cu′biti. See *Biceps flexor cubiti.*

Bi′ceps exte′rnus. See *Triceps extensor cubiti.*

BI′CEPS FLE′XOR CRU′RIS. *Biceps cruris* of Albinus. *Biceps* of Winslow. Douglas, and Cowper, and *Ischio-femoroperonien* of Dumas. A muscle of the leg, situated on the hind part of the thigh. It arises by two distinct heads; the first, called *longus*, arises in common with the semitendinosus, from the upper and posterior part of the tuberosity of the os ischium. The second, called *brevis*, arises from the linea aspera, a little below the termination of the glutæus maximus, by a fleshy acute beginning, which soon grows broader as it descends to join with the first head, a little above the external condyle of the os femoris.

It is inserted, by a strong tendon, into the upper part of the head of the fibula. Its use is to bend the leg. This muscle forms what is called the outer hamstring; and, between it and the inner, the nervus popliteus, arteria and vena poplitea, are situated.

BI'CEPS FLE'XOR CU'BITI. *Biceps brachii* of Albinus. *Coraco-radialis, seu biceps* of Winslow. *Biceps internus* of Douglas. *Biceps internus humeri* of Cowper. *Scapulo-coracoradial* of Dumas. A muscle of the fore-arm, situated on the fore part of the *os humeri.* It arises by two heads. The first and outermost, called *longus,* begins tendinous from the upper edge of the glenoid cavity of the scapula, passes over the head of the os humeri within the joint, and in its descent without the joint, is inclosed in a groove near the head of the os humeri, by a membranous ligament that proceeds from the capsular ligament and adjacent tendons. The second, or innermost head, called *brevis,* arises, tendinous and fleshy, from the coracoid process of the scapula, in common with the coracobrachialis muscle. A little below the middle of the fore-part of the os humeri, these heads unite. It is inserted by a strong roundish tendon into the tubercle on the upper end of the radius internally. Its use is to turn the hand supine, and to bend the fore-arm. At the bending of the elbow, where it begins to grow tendinous, it sends off an aponeurosis, which covers all the muscles on the inside of the fore-arm, and joins with another tendinous membrane, which is sent off from the triceps extensor cubiti, and covers all the muscles on the outside of the fore-arm, and a number of the fibres, from opposite sides, decussate each other. It serves to strengthen the muscles, by keeping them from swelling too much outwardly when in action, and a number of their fleshy fibres take their origin from it.

Bi'ceps inte'rnus. See *Biceps flexor cubiti.*

Bichi'chiæ. An epithet of certain pectorals, or rather troches, described by Rhazes, which were made of liquorice, &c.

Bi'chos. A Portuguese name for the worms that get under the toe of the people in the Indies, which are destroyed by the oil of cashew nut.

Bi'corn. (*Bicornis:* from *bis,* twice, and *cornu,* an horn.) An epithet sometimes applied to the os hyoides, which has two processes, or horns; and likewise, in former times, to muscles that had two terminations.

BICU'SPIS. (*Bicuspis:* from *bis,* twice, and *cuspis,* a spear.) The name of those teeth which have double points, or fangs. See *Teeth.*

BI'DENS. (From *bis,* twice, and *dens,* a tooth; so called from its being deeply serrated, or indented.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia æqualis.*

BIDLOO, Godfrey, a celebrated anatomist, born at Amsterdam, in 1649. After practising several years as a surgeon, he was appointed physician to William III. and in 1694, made professor of anatomy and surgery at Leyden. He published 105 very splendid, though rather inaccurate anatomical tables, with explanations; and several minor works. His nephew, *Nicholas,* was physician to the Czar, Peter I.

Bifurcated. (*Bifurcus:* from *bis,* twice, and *furca,* a fork.) A vessel, or nerve, is said to bifurcate when it divides into two branches; thus the bifurcation of the aorta, &c.

Biga'ster. (*Bigaster:* from *bis,* twice, and γαϛηρ, a belly.) A name given to muscles which have two bellies.

Bihe'rnius. (From *bis,* double, and *hernia,* a disease so called.) Having a hernia, or rupture, on each side of the scrotum.

Bila'den. A name of iron.

BILE. (*Bilis.* Nævius derives it from *bis,* twice, and *lis,* contention; as being supposed to be the cause of anger and dispute.) The gall. A bitter fluid, secreted in the glandular substance of the liver; in part flowing into the intestines, and in part regurgitating into the gall-bladder. The secretory organ of this fluid is the penicilli of the liver, which terminate in very minute canals, called biliary ducts. The biliary ducts pour their bile into the *ductus hepaticus,* which conveys it into the *ductus communis choledochus,* from whence it is in part carried into the duodenum. The other part of the bile regurgitates through the cystic duct (see *Gall-bladder,*) into the gall-bladder: for hepatic bile, except during digestion, cannot flow into the duodenum, which contracts when empty; hence it necessarily regurgitates into the gall-bladder. The branches of the *vena portæ* contribute most to the secretion of bile; its peculiar blood, returning from the abdominal viscera, is supposed to be, in some respects, different from other venal blood, and to answer exactly to the nature of bile. It is not yet ascertained clearly whether the florid blood, in the hepatic artery, merely nourishes the liver, or whether, at the same time, it contributes a certain principle, necessary for the formation of bile. It has been supposed, by physiologists, that cystic bile was secreted by the arterial vessels of the gall-bladder; but the fallacy of this opinion is proved by making a ligature on the cystic duct of a living animal. From what has been said, it appears that there are, as it were, two kinds of bile in the human body:—

1. *Hepatic bile,* which flows from the liver into the duodenum: this is thin, of a faint yellow colour, inodorous, and very slightly

bitter, otherwise the liver of animals would not be eatable.

2. *Cystic bile*, which regurgitates from the hepatic duct into the gall-bladder, and there, from stagnating, becomes thicker, the aqueous part being absorbed by lymphatic vessels, and more acrid from concentration. Healthy bile is of a yellow, green colour; of a plastic consistence, like thin oil, and when very much agitated, it froths like soap and water: its smell is fatuous, somewhat like musk, especially the putrefying or evaporated bile of animals: its taste is bitter. The constituent principles of bile are:

1. *Water*, which constitutes the greatest part of bile.

2. *An albuminous principle*, precipitated by alkohol and mineral acids.

3. *A resinous principle*, obtained by evaporating a tincture made of alkohol and bile.

4. *A colouring principle*, which adheres to the resinous part, and gives the colour to bile.

5. *Soda*, in its caustic state: hence healthy bile does not effervesce with acids, and affords a neutral salt.

6. *Phosphate of lime.*

The primary uses of this fluid, so important to the animal economy, are:

1. *To separate the chyle from the chyme:* thus chyle is never observed in the duodenum before the chyme has been mixed with the bile: and thus it is that oil is extricated from linen by the bile of animals.

2. By its *acridity* it excites the peristaltic motion of the intestines; hence the bowels are so inactive in people with jaundice.

3. It imparts a *yellow colour* to the excrements; thus we observe the white colour of the fæces in jaundice, in which disease the flow of bile into the duodenum is entirely prevented.

4. It prevents the *abundance of mucus and acidity* in the primæ viæ; hence acid, pituitous, and verminous saburra are common from deficient or inert bile.

BILGUER, John Ulrick, was born at Coire, in Swisserland. He practised surgery at Berlin with such reputation, that he was appointed by the great Frederick, Surgeon-General to the Prussian army. It was then the general practice to amputate in bad compound fractures; and being struck with the small proportion of those, who recovered after the operation, he was led to try more lenient methods; from which meeting with much better success, he published as a thesis, on graduating at Halle, in 1761, a pretty general condemnation of amputation. This work attracted much notice throughout Europe, and materially checked the unnecessary use of the knife. In his "Instructions for Hospital Surgeons," which appeared soon after, he insisted farther on the same subject; and where amputation was unavoidable, he advised leaving a portion of the integuments, which is now generally adopted.

Bi′liary duct. *Ductus biliosus.* The very vascular *glandules*, which compose almost the whole substance of the liver, terminate in very small canals, called *biliary ducts*, which at length from one trunk, the *ductus hepaticus.* Their use is to convey the bile, secreted by the liver, into the hepatic duct; this uniting with a duct from the gall-bladder, forms one common canal, called the *ductus communis choledochus*, which conveys the bile into the intestinal canal.

Bili′mbi. (Indian.) See *Malus Indica.*

Bi′lious. A term very generally made use of, to express diseases which arise from too copious a secretion of bile: thus bilious colic, bilious diarrhœa, bilious fever, &c.

BI′LIS. See *Bile.*

Bi′lis a′tra. Black bile. The supposed cause among the antients of melancholy.

Bi′lis cy′stica. *Bilis fellea.* Cystic bile. The bile when in the gall-bladder is so called to distinguish it from that which is found in the liver.

Bi′lis hepa′tica. Hepatic bile. The bile when it has not entered the gall-bladder.

Bi′lobus. (From *bis*, double, and *lobus*, the end of the ear.) Having two lobes, resembling the tips of ears.

Bime′stris. (From *bis*, twice, and *mensis*, month.) Two months old.

Bindweed. See *Convolvulus sepium.*

Binga′lle. See *Casumuniar.*

Bino′culus. (From *binus*, double, and *oculus*, the eye.) A bandage for securing the dressings on both eyes.

Bi′nsica. A disordered mind. *Helmont.*

Bi′nsica mors. The binsical, or that death which follows a disordered mind.

Bioly′chnium. (From βιος, life, and λυχνιον, a lamp.) Vital heat: an officinal nostrum.

Bi′ote. (From βιος, life.) Life. Light food.

Biotha′nati. (From βια, violence, or βιος, life, and ϑανατος, death.) Those who die a violent death, or suddenly, as if there were no space between life and death.

Bipemu′lla. See *Pimpinella.*

Bipene′lla. See *Pimpinella.*

Bi′ra. Malt liquor or beer.

Bira′o. Stone parsley.

Birch tree. See *Betula.*

Birdstongue. A name given to the seeds of the *Fraxinus excelsior* of Linnæus.

Bi′rsen. (Heb. an aperture.) A deep ulcer, or imposthume in the breast.

Birthwort, climbing. See *Aristolochia clematitis.*

Bisco′ctus. (From *bis*, twice, and *coquo*, to boil.) Twice dressed. It is chiefly applied to bread much baked, as biscuit.

Biscute′lla. Mustard.

Bise′rmas. A name formerly given to clary, or garden clary.

Bishop's weed. See *Ammi.*

Bisli'ngua. (From *bis*, twice, and *lingua*, a tongue; so called from its appearance of being double-tongued; that is, of having upon each leaf a less leaf.) The Alexandrian laurel.

Bisma'lva. (From *vismalva*, *quasi viscum malva*, from its superior viscidity.) The water, or marsh-mallow.

BI'SMUTH. (*Bismut*, Germ.) *Bismuthum.* A metal which is found in the earth in very few different states, more generally native or in the metallic state. *Native bismuth* is met with in solid masses, and also in small particles dispersed in and frequently deposited on different stones, at Schreeberg in Saxony, Sweden, &c. Sometimes it is crystallized in four-sided tables, or indistinct cubes. It exists combined with oxygen in the *oxide of bismuth* (*bismuth ochre*), found in small particles, dispersed, of a blueish or yellowish-grey colour, needle-shaped and capillary; sometimes laminated, forming small cells. It is also, though more seldom, united to sulphur and iron in the form of a sulphuret in the *martial sulphuretted bismuth ore.* This ore has a yellowish-grey appearance, resembling somewhat the martial pyrites. And, it is sometimes combined with arsenic.

Properties.— Bismuth is of a silver-white colour inclining to red. It soon tarnishes and becomes irridescent. It is brittle and can easily be reduced to small particles. It is soft enough to be cut with a knife. It has a lamellated texture. Its specific gravity is 9.800. It requires less heat for fusion than any other metal, tin excepted, melted by a heat=460 deg. Fahr. It can be volatilized by heat and escapes in the state of greyish-white vapour. It readily unites with mercury and with sulphur. When fused, it exhibits on cooling, cubical figures on the surface. It is soluble in sulphuric, nitric, and muriatic acids. The solution in nitric acid is decomposable by mere dilution with pure water. It inflames in oxygenated muriatic acid gas. It is capable of combining with the greatest number of the metals; and when in certain proportions, promotes their fusibility remarkably. It speedily becomes black by sulphuretted hydrogen gas.

Bismu'thum. (From *bismut*, German.) See *Bismuth.*

BISSET, Charles, was born about the year 1716. After studying at Edinburgh, and practising some years as an Hospital-Surgeon in Jamaica, he entered the army; but soon after settled in Yorkshire, and in 1755, published a Treatise on the Scurvy. But his most celebrated work is an "Essay on the medical Constitution of Great Britain," in 1762. He obtained three years after a diploma from St. Andrews, and reached his 75th year.

Bistort. See *Bistorta.*

BISTO'RTA. (From *bis*, twice, and *torqueo*, to bend; so called from the contortions of its roots.) Bistort. See *Polygonum bistorta.*

Bistoury. (*Bistoire*, French.) Any small knife for surgical purposes.

Bi'thinos. A Galenical plaster.

Bithi'nici emplastrum. A plaster for the spleen.

Bitter apple. See *Cucumis Colocynthis.*

BIT NOBEN. Salt of bitumen. A white saline substance has lately been imported from India by this name, which is not a natural production, but a Hindoo preparation of great antiquity. It is called in the country, *bit noben, padnoon,* and *soucherloon*, and popularly *khala mimuc*, or black salt. Mr. Henderson, of Bengal, conjectures it to be the *sal asphaltites*, and *sal sodomenus* of Pliny and Galen. This salt is far more extensively used in Hindostan than any other medicine whatever. The Hindoos use it to improve their appetite and digestion. They consider it as a specific for obstructions of the liver and spleen; and it is in high estimation with them in paralytic disorders, particularly those that affect the organs of speech, cutaneous affections, worms, old rheumatisms, and indeed all chronic disorders of man and beast.

BITU'MEN. (*ϖιτύμα, ϖιτυς*, pine; because it flows from the pine-tree; or, *quòd vi tumeat è terra*, from its bursting forth from the earth.) Bitumens are combustible, solid, soft, or fluid substances, whose smell is strong, acrid, or aromatic, composed of hydrogen and carbon with a contamination of earth and other substances in small proportions. They are found either in the internal part of the earth, or exuding through the clefts of the rocks, or floating on the surface of waters. Like oils they burn with a rapid flame. Natural historians have divided them into several genera; but modern chemists arrange them according to their chemical properties, and are only acquainted with six species, which are very distinct from each other: these are, naphtha, amber, asphaltos, jet, pit-coal, and petroleum.

Bitu'men barbade'nse. See *Petroleum barbadense.*

Bitu'men juda'icum. *Asphaltus.* Jews' pitch. A solid light bituminous substance, of a dusky colour on the outside, and a deep shining black within; of very little taste, and scarcely any smell, unless heated, when it emits a strong pitchy one. It is said to be found plentifully in the earth in several parts of Egypt, and floating on the surface of the Dead Sea. It is now wholly expunged from the catalogue of officinals of this country; but was formerly esteemed as a discutient, sudorific, and emmenagogue.

Bitu'men li'quidum. See *Petroleum.*

BIVE'NTER. (*Biventer*; from *bis*, twice, and *venter*, a belly.) A muscle is so termed, which has two bellies.

Bive′nter cervi′cis. A muscle of the lower jaw.

Bive′nter maxi′llæ inferio′ris. See *Digastricus*.

Bi′xa orlea′na. The systematic name for the plant affording the *terra orleana* of the pharmacopœias. The substance so called is a ceraceous mass obtained from the seeds of the *Bixa orleana* of Linnæus. In Jamaica and other warm climates, it is considered as a useful remedy in dysentery, possessing adstringent and stomachic qualities.

Bla′cciæ. The measles. *Rhazes.*

Bla′ckberry. The fruit of the common bramble, *Rubus fruticosus* of Linnæus: which see.

BLACKMORE, Sir Richard, was born in Wiltshire about the year 1650. After studying at Oxford, he took his degree in medicine at Padua, then settled in London, and met with considerable success, insomuch that he was appointed physician to William III. and retained the same office under Queen Anne. He then published several long and dull epic poems, which appear to have materially lessened his reputation; so that his opposition to the inoculation for small-pox had very little weight. He wrote also several medical tracts, which are little known at present.

Bladder. See *Urinary bladder*, and *Gall-bladder.*

Bladder, inflamed. See *Cystitis.*

Blade-bone. See *Scapula.*

Blæ′sitas. (From *blæsus.*) A defect in speech, called stammering.

Blæ′sus. (From *βλαπτω*, to injure.) A stammerer.

Bla′nca. (*Blanc*, French.) A purging mixture; so called because it was supposed to evacuate the white phlegmatic humours. Also white lead.

Bla′nca muli′erum. White lead.

BLANCARD, Stephen, was born at Leyden, and graduated at Franeker, in 1678. He settled at Amsterdam, and published many anatomical and medical works; especially one on morbid anatomy, containing 200 cases, and a "Lexicon Medicum," which passed through numerous editions.

Bla′sa. (Indian.) A tree, the fruit of which the Indians powder, and use to destroy worms.

BLASIUS, Gerard, son of a physician at Amsterdam, from whom he derived a great predilection for comparative anatomy. After graduating at Leyden about the year 1646, he returned to his native city, and acquired so much reputation, that he was made professor of medicine in 1660, and soon after physician to the hospital. Besides publishing new editions of several useful works, with notes comprehending subsequent improvements, he was author of various original ones, especially relating to comparative and morbid anatomy. He claimed the discovery of the ductus salivaris, asserting he had pointed it out to Steno; to whom it has been commonly ascribed.

Blaste′ma. (From *βλαςανω*, to germinate.) A bud or shoot. Hippocrates uses it to signify a cutaneous pimple like a bud.

Bla′stum mosylitum. Cassia bark kept with the wood.

Bla′tta. (From *βλαττω*, to hurt.) A sort of beetle, or bookworm; so called from its injuring books and clothes: the kermes insect.

Blatta′ria lu′tea. (From *blatta*; so called, because, according to Pliny, it engenders the blatta.) The herb yellow moth-mullein.

Ble′chon. (From *βληχαομαι*, to bleat; so called according to Pliny, because if sheep taste it they bleat.) The herb wild penny-royal.

Bleeding. See *Blood-letting* and *Hæmorrhage.*

Bleeding at the nose. See *Epistaxis.*

Ble′ma. (From *βαλλω*, to inflict.) A wound.

Ble′nde. A species of zinc ore, formed of zinc in combination with sulphur.

Ble′nna. (*βλεννὰ.*) *Blena.* Mucus, a thick excrementitious humour.

BLENNORRHA′GIA. (From *βλεννα*, mucus, and *ρεω*, to flow.) The discharge of mucus from the urethra.

BLENNORRHŒ′A. (From *βλεννα*, mucus, and *ρεω*, to flow.) *Gonorrhœa mucosa.* A gleet. A discharge of mucus from the urethra, arising from weakness.

Ble′phara. (*Quasi βλεπους φαρος*, as being the cover and defence of the sight.) The eyelids.

Blepha′rides. (From *βλεφαρον.*) The hair upon the eyelids; also the part of the eyelids where the hair grows.

BLEPHAROPHTHA′LMIA. (From *βλεφαρον*, the eyelid, and *οφθαλμλια*, a disease of the eye.) An inflammation of the eyelid.

BLEPHAROPTO′SIS. (From *βλεφαρον*, the eyelid, and *ϖτωσις*, from *ϖιπτω*, to fall.) A prolapse, or falling down of the upper eyelid, so as to cover the cornea.

Blepharo′tis. (From *βλεφαρον*, the eyelid.) An inflammation of the eyelids.

Blepharoxy′ston. (From *βλεφαρον*, the eyelid, and *ξεω*, to scrape off.) A brush for the eyes. An instrument for cleansing or scraping off foul substances from the eyelids.

Blepharo′xysis. (From *βλεφαρον*, the eyelid, and *ξεω*, to scrape off.) The cleansing of the eyelids. Inflammation of the eyelids.

Blessed Thistle. See *Centaurea benedicta.*

Blestri′smus. (From *βαλλω*, to throw about.) Phrenetic restlessness.

Ble′ta. A word used by Paracelsus to signify white, and applied to urine when it is milky, and proceeds from a disease of the kidneys.

Ble'ti. (*Bletus*, from βαλλω, to strike.) Those seized with dyspnœa or suffocation.

BLI'STER. *Vesicatorium. Emplastrum vesicatorium.* A topical application which when put on the skin raises the cuticle in the form of a vesicle, filled with a serous fluid. Various substances produce this effect on the skin; but the powder of the *lytta vesicatoria*, or blistering fly, is what operates with most certainty and expedition, and is now invariably made use of for the purpose.

When it is not wished to maintain a discharge from the blistered part, it is sufficient to make a puncture in the cuticle to let out the fluid; but when the case requires keeping up a secretion of pus, the surgeon must remove the whole of the detached cuticle with a pair of scissars, and dress the excoriated surface in a particular manner. Practitioners used formerly to mix powder of cantharides with an ointment, and dress the part with this composition. But such a dressing not unfrequently occasioned very painful affections of the bladder, a scalding sensation in making of water, and very afflicting stranguries. The treatment of such complaints consists in removing every particle of the fly from the blistered part, making the patient drink abundantly of mucilaginous drinks, giving emulsions and some doses of camphor.

These objections to the employment of salves containing the lytta, for dressing blistered surfaces, led to the use of mezereon, euphorbium, and other irritating substances, which, when incorporated with ointment, form very proper compositions for keeping blisters open, which they do without the inconvenience of irritating the bladder, like the blistering fly. — The favourite application, however, for keeping open blisters, is the savine cerate, which was brought into notice by Mr. Crowther in his book on white swellings. (See *Ceratum Sabinæ.*) On the use of the savine cerate, immediately after the cuticle raised by the blister is removed, says Mr. Crowther, it should be observed that experience has proved the advantage of using the application lowered by a half or two-thirds of the unguentum ceræ. An attention to this direction will produce less irritation and more discharge, than if the savine cerate were used in its full strength. Mr. Crowther says also, that he has found fomenting the part with flannel, wrung out of warm water, a more easy and preferable way of keeping the blistered surface clean, and fit for the impression of the ointment, than scraping the part, as has been directed by others. An occasional dressing of unguentum resinæ flavæ, he has found a very useful application for rendering the sore free from an appearance of slough, or rather dense lymph, which has sometimes been so firm in its texture as to be separated by the probe, with as much readiness as the cuticle is detached after blistering. As the discharge diminishes, the strength of the savine dressing should be proportionably increased. The ceratum sabinæ must be used in a stronger or weaker degree, in proportion to the excitement produced on the patient's skin.

Blister-fly. See *Lytta.*

Bli'tum fœ'tidum. See *Chenopodium vulvaria.*

BLONDEL, James Augustus, was born in England of a French family, and admitted licentiate of the College of Physicians about 1720. He chiefly distinguished himself by controverting, in a very able manner, the opinion then generally received, that marks could be imprinted on the fœtus by the imagination of the mother, and he has the merit of contributing very largely to the removal of this prejudice, which had prevailed for ages, and often produced much mischief.

BLOOD. *Sanguis.* A red homogeneous fluid, of a saltish taste, and somewhat urinous smell, and glutinous consistence, which circulates in the cavities of the heart, arteries, and veins. The quantity is estimated to be about twenty-eight pounds in an adult: of this, four parts are contained in the veins, and a fifth in the arteries. The colour of the blood is red; in the arteries it is of a florid hue, in the veins darker; except only the pulmonary vessels, in which the colour is reversed. Physiology demonstrates, that it acquires this florid colour in passing through the lungs, and from the loss of carbon. The blood is the most important fluid of our body. Some physicians and anatomists have considered it as alive, and have formed many ingenious hypotheses in support of its vitality. The temperature of this fluid is of considerable importance, and appears to depend upon the circulation and respiration. The blood of man, quadrupeds, and birds, is hotter than the medium they inhabit; hence they are termed animals of warm blood; whilst in fishes and reptiles, animals with cold blood, it is nearly of the temperature of the medium they inhabit. The microscope discovers that the blood contains a great number of round globules, which are seen floating about in a yellowish fluid, the serum. The blood also possesses remarkable physical properties; its taste is saltish, and the smell of its halitus or vapour, when recently drawn, is somewhat urinous; it is of a plastic consistence, somewhat glutinous and adhesive.

Chemical analysis of blood, by means of distillation, discovers,

1. A considerable quantity of *insipid water*, which very soon becomes putrid.
2. *Empyreumatic oil.*
3. *Ammoniacal spirit.*
4. *Carbon*, which remains behind, is very spongy, and with great difficulty incinerated. The ashes, however, consist of a small quantity of culinary salt, soda, phosphate of lime, and a very small portion of iron.

While hot, and in motion, the blood remains constantly fluid, and red: when it cools, and is at rest, it takes the form of a fluid mass, which gradually and spontaneously separates into two parts; the one, which is red and floating, becomes of a darker colour, remains concrete, and is called the *cruor*, *crassamentum*, or *cake;* the other, which occupies the lower part of the vessel, is of a yellow-greenish colour, and adhesive, and is called the *serum* or *lymph.*

The CRUOR forms more than one half of the blood; it is very plastic, thick, and, in consistence, like glutinous jelly. It soon putrefies in the temperature of the air; but, dried by a gentle heat, becomes a brittle, dark, red mass. It is insoluble in water; and, when boiled in it, is converted into a hard grumous mass, internally red. The surface of the cruor of the blood, after being exposed in a vessel to atmospheric air, becomes of a florid red colour; but the inferior surface, contiguous to the vessel, is of a deep black: the change of colour on the surface is owing to the oxygen of the atmosphere acting upon the blood. The cruor of the blood is composed of,

1. *Red globules*, which chemistry demonstrates consist of a fibrous gluten and iron. The experiments of the celebrated Rhades shew, that from twenty-five pounds of blood from the human body, near two drachms of the oxide of iron were obtained.

2. The fibrous gluten of the cruor, is that which remains after washing the cruor of blood for a considerable time in cold water, and enclosed in a fine linen cloth; in which case the red globules are washed away. If the red water obtained in this experiment be evaporated, and then distilled to dryness, it leaves behind a carbon, exhibiting, when incinerated, a great quantity of iron, attractable by the magnet. From these experiments it would appear, that the redness of the globules is imparted from the oxidated iron, for which purpose a small quantity is sufficient.

The SERUM of the blood is a lymphatic fluid, almost inodorous; rather saltish to the taste; pellucid, and of a yellowish-green colour; and rather of a plastic consistence. It forms scarcely one half of the blood; and it contains,

1. A large portion of *water;* from forty-seven ounces of serum, forty-three of insipid water were yielded by distillation.

2. *Albuminous gluten*, like the white of an egg, obtained by boiling, or by stirring it with a stick, or by an admixture of alkohol or concentrated mineral acid. If equal parts of water and serum of the blood be coagulated by fire, that part of the serum which is not coagulated, upon being cooled, puts on the appearance of a tremulous jelly.

3. *Carbonated soda*, obtained by pouring a mineral acid upon recent diluted serum.

4. *Culinary salt*, found in the incinerated carbon of blood. The albuminous principle of the serum, more commonly called the coagulable lymph, appears to be of very considerable importance in the animal economy, both in diseased and healthy states of it: it affords, by analysis, carbon, azote, and hydrogen.

The importance of the blood is very considerable; it distends the cavities of the heart and blood-vessels, and prevents them from collapsing; it stimulates to contraction the cavities of the heart and vessels, by which means the circulation of the blood is performed; it generates within itself animal heat, which it propagates throughout the body; it nourishes the whole body: and, lastly, it is that source from which every secretion of the body is separated.

Blood, dragon's. See *Calamus rotang.*

BLOOD-LETTING. Under this term is comprehended every artificial discharge of blood made with a view to cure or prevent a disease. Blood-letting is divided into *general* and *topical.* As examples of the former, *venæsection* and *arteriotomy* may be mentioned; and of the latter, the *application* of *leeches*, *cupping-glasses*, and *scarification.*

Blood, spitting of. See *Hæmoptysis.*

Blood, vomiting of. See *Hæmatemesis.*

Blood-stone. See *Hæmatites.*

Bloody flux. See *Dysenteria.*

BO'A. (From βους, an ox.) A pustulous eruption like the small-pox, so called because it was cured, according to Pliny, by anointing it with hot ox-dung: also the name of a serpent of Calabria; and of the hydroa.

BOCHE'TUM. A decoction of the woods prepared by a second boiling with fresh water.

BO'CHIA. A subliming vessel.

BO'CHIUM. A swelling of the bronchial glands.

BODIES, COMBUSTIBLE. This term is given by chemists to all substances which, on account of their affinity for oxygen, are capable of burning.

BODIES, GASEOUS. See *Gas.*

BODIES, INFLAMMABLE. Chemists give this name to such bodies as burn with facility, and flame in an increased temperature; although, strictly speaking, all combustible bodies are inflammable bodies: such are the diamond, sulphur, bitumens, &c.

BODIES, PHOSPHORESCENT. Bodies which produce light, though their temperature be not increased.

BODY. *Corpus.* The human body is divided by anatomists into the trunk and extremities: *i. e.* the head, and inferior and superior extremities, each of which have certain regions before any part is removed, by which the physician is enabled to direct the application of blisters and the like, and the situation of diseases is better described.

The head is distinguished into the hairy part and the face. The former has five regions, viz. the crown of the head or *vertex*, the fore-part of the head or *sinciput*, the hind-part or *occiput*, and the sides, *partes laterales capitis*. In the latter are distinguished, the region of the forehead, *frons*; temples, or *tempora*; the nose, or *nasus*; the eyes, or *oculi*; the mouth, or *os*; the cheeks, *buccæ*; the chin, or *mentum*; and the ears, or *aures*.

The trunk is distinguished into three principal parts, the neck, thorax, and abdomen. The neck is divided into the anterior region or *pars antica*, in which, in men, is an eminence called *pomum Adami*; the posterior region is called *nucha colli*; and the laterial regions, *partes laterales colli*.

The thorax is distinguished into the anterior region, in which are the *sternum* and *mammæ*, and at whose inferior part is a pit or hollow called *scrobiculus cordis*; a posterior region, called *dorsum*; and the sides, or *latera thoracis*.

The abdomen is distinguished into an anterior region, properly the *abdomen*; a posterior region, called the loins, or *lumbi*; and lateral regions or flanks, called *latera abdominis*. The anterior region of the abdomen being very extensive, is subdivided into the *epigastric*, *hypochondriac*, *umbilical*, and *hypogastric* regions, which are described under their respective names. Immediately below the abdomen is the *mons Veneris*, and at its sides the groins or *inguina*. The space between the organs of generation and the *anus*, or fundament, is called the *perinæum*.

The superior extremity is distinguished into the shoulder, *summitas humeri*, under which is the arm-pit, called *axilla* or *fovea axillaris*; the *brachium*, or *arm*; the *antibrachium*, or fore-arm, in which anteriorly is the bend of the arm, where the veins are generally opened, called *flexura antibrachii*; and posteriorly the elbow, called *angulus cubiti*; and the hand, in which are the *carpus* or wrist, the back or *dorsum manûs*, and the palm or *vola*.

The inferior extremity is divided into, 1. the region of the femur, in which is distinguished the *coxa* or *regio ischiadica*, forming the outer and superior part; 2. the leg, in which are the knee or *genu*, the bend or *cavum poplitis*, and the calf or *sura*; 3. the foot, in which are the outer and inner ankle, or *malleolus externus* and *internus*, the back or *dorsum*, and the sole or *planta*.

Bo'e. (From βοαω, to exclaim.) Clamour, or moaning made by a sick person.

BOERHAAVE, Herman, was born at Voorhout, in Holland, December 31, 1668. His father, the pastor of the village, having nine children, educated them himself, and intending Herman for the church, was careful to ground him well in the learned languages; in which he made such rapid progress, that he was sent at 14 to Leyden. His father dying soon after in slender circumstances, he was fortunately supported by the burgomaster, Daniel Van Alphin; which Boerhaave ever remembered with gratitude. Among other studies, he was very partial to the mathematics, and improved so much, as to be able to give private instructions in them, whereby he partly maintained himself. In 1690, he took his degree in philosophy, and in an inaugural thesis refuted the errors of the materialists. But he soon after turned his mind to the study of medicine, and attended dissections under Nuck; he greatly preferred Hippocrates among the antient, and Sydenham among the modern physicians. He was made doctor of medicine at Harderwyck, in 1693; and in his dissertation on that occasion, insisted on the utility of observing the excretions in disease, especially the urine. He was then engaged in forming a new theory of medicine, by a judicious selection from all that had been before advanced; which was so well arranged, and so ably supported by him, that it became generally adopted, and prevailed throughout Europe for more than half a century. He gave also lectures on chemistry, with considerable reputation, about the same period. The university of Leyden therefore appointed him, in 1701, professor of the theory of medicine; when he read an oration recommending the study of Hippocrates; and, as he declined some very advantageous offers from other parts, they afterwards augmented his salary. About this time, he published another Latin oration, "On the Use of mechanical Reasoning in Medicine," which contributed to extend his fame. In 1709, he was appointed professor of botany, to which study he was ever after eminently attached. On that occasion he produced another oration, maintaining that medicine would be best improved by observation, and by simplicity in prescriptions. His "Aphorisms" had appeared the year before, giving a brief account of the history and cure of diseases, a work universally admired; to which his pupil Van Swieten afterwards attached a very ample commentary. About the same time, he published his "Institutes," treating of physiology. These two works, with successive improvements, passed through numerous editions, and were translated into every European, nay even into the Arabic language. In the year after, he printed a catalogue of the plants in the university garden. In 1714, he was made rector of the university, and at the end of the year for which he held the office, delivered a discourse "On attaining Certainty in Physics." About this period he was made professor of the practice of medicine, and in 1718, of chemistry also. His lectures on these subjects, and on botany, were delivered with such clearness and precision, that students thronged from every part to hear him; insomuch that Leyden could scarcely afford accommodations for them. He was also often consulted in difficult cases by physicians even in distant parts of the world. When appointed to the chemical chair, he had published a short work on that subject; but some of his pupils having printed his lectures without authority, and very incorrectly, he was led to prepare them for the press in 1732. In his conversation, Boerhaave was generally familiar, in his demeanour grave, but disposed to occasional pleasantry: he was distinguished for piety, and on his moral character, his disciple Haller has passed a very high eulogium. Having acquired considerable wealth by his exertions, and being plain in his dress, as well as abstemious in his diet, he was by some accused of parsimony: but he spared no reasonable expense in procuring rare books, and foreign plants. Being of a vigorous constitution, and accustomed to much exercise abroad, he met with little interruption from illness; but in 1729, having become corpulent, and incapable of riding, his health began to suffer, and he was induced to resign his botanical and chemical appointments. In an oration then delivered, he recounted the chief events of his life, expressing himself grateful for the patronage which he had received from individuals; as well as to his own profession, for the little opposition shewn to his opinions. It perhaps never happened, that so great a revolution in science was so readily brought about. The great reputation acquired by his extensive abilities, and the moderation of his character, particularly averse from contention, no doubt contributed materially to this result. In the year following, he was again made rector of the university of Leyden; and also elected a fellow of the Royal Society in London, having been previously admitted to the Royal Academy of Sciences in Paris. The remainder of his life was chiefly occupied in revising his own numerous productions, in publishing more correct editions of several esteemed authors, and in domestic recreations at his seat near Leyden, with his wife and daughter. Towards the end of 1737, he was attacked with symptoms of disease in the chest, which terminated his existence in the September following. His fellow-citizens erected an elegant monument to his memory.

Boethe'ma. (From βοηθεω, to assist.) A remedy.

Boethema'tica. (From βοηθεω, to assist.) Favourable symptoms.

Bog-bean. See *Menyanthes trifoliata.*

Bo'gia gu'mmi. Gamboge.

Bohea tea. See *Thea.*

BOHN, John, was born at Leipsic, in 1640; and after studying in many parts of Europe, graduated there; and was made successively professor of anatomy, and of therapeutics, public physician to the city, &c. Among numerous publications, he chiefly distinguished himself by his "Circulus anatomico physiologicus," and a treatise "De officio medici clinico et forensi," which latter particularly has great merit. He also well explained the judgment to be formed concerning wounds; and recommended purging with calomel in the beginning of small-pox. He died in 1718.

Bois de coissi. See *Quassia.*

Bolar earths. See *Bole.*

BOLE. (Βωλος, a mass.) A friable earthy substance, uniting with water into a smooth paste, adhering to the tongue, and dissolving as it were in the mouth; it is of the argillaceous or clay kind, but more readily imbibing water than the clays strictly so called. Those used in medicine, are the Armenian and French boles. See *Bole Armenian*, and *Bolus Gallica.* Many other bolar earths have been recommended for medicinal uses, and were formerly ranked amongst the officinals; as red boles from Armenia, Lemnos, Strigonium, Portugal, Tuscany, and Livonia; yellow boles from Armenia, Tockay, Silesia, Bohemia, and Blois; white boles from Armenia, Lemnos, Nocera, Eretria, Lamos, Chio, Malta, Tuscany, and Goltberg. Several of these earths have been commonly made into little cakes or flat masses, and stamped with certain impressions; from which circumstance they received the name of *terræ sigillatæ*, or sealed earths.

BOLE, ARMENIAN, *Bolus Armeniæ.* Bole armenic. A pale, but bright red coloured earth, which is occasionally mixed with honey, and applied to children's mouths when afflicted with aphthæ. It forms, like all argillaceous earths, a good tooth-powder, when mixed with some aromatic.

BOLE'TUS. (From *βωλος*, a mass, or *βωλιτης*, from its globular form.)

The name of a genus of plants in the Linnæan system. Class, *Cryptogamia.* Order, *Fungi.* Boletus. Spunk.

Bole'tus ce'rvi. The mushroom.

Bole'tus ignia'rius. The systematic name for the *agaricus* of the pharmacopœias. *Agaricus chirurgorum. Agaricus quercûs. Fungus igniarius.* Agaric of the oak. Touchwood boletus. Female agaric. This fungus *Boletus igniarius — acaulis pulvinatus levis, poris tenuissimis* of Linnæus, has been much used by surgeons as an external styptic. Though still employed on the Continent, the surgeons in this country have not much confidence in it.

Bole'tus la'ricis. The systematic name for the officinal *agaricus albus.* The plant known by this name in the pharmacopœias, is the *Boletus laricis* of Linnæus; so called from its being met with on old larch trees, in different parts of Europe. Several preparations, as troches, an extract, and pills, are ordered to be made with it in foreign pharmacopœias, which are administered against phthisical complaints.

BOLE′TUS PI′NI LA′RICIS. A species of agaric.

BOLE′TUS SUAVE′OLENS. The systematic name for the *fungus salicis* of the pharmacopœias. The species of fungus ordered in some pharmacopœias by this name, is the *Boletus suaveolens; acaulis superne lævis, salicibus*, of Linnæus, and the *Boletus albus* of Hudson. When fresh, it has a suburinous smell, and at first an acid taste, followed by a bitter. It is seldom used at present, but was formerly given in phthisical complaints.

BOLI′SMUS. A voracious appetite, according to Avicenna; but most probably meant for bulimus.

BOLUS. (Βωλος, a bole or bolus.) Any medicine, rolled round, that is larger than an ordinary sized pea, and yet not too large to be swallowed.

BO′LUS ALEXIPHA′RMICA. A preparation of contrayerva.

BO′LUS EX ALU′MINE. Alum, bark, and nutmeg.

BO′LUS A′RMENA. See *Bole, Armenian.*

BOLUS A′RMENA A′LBA. The white armenian bole.

BO′LUS ARMO′NIAC. See *Bole, Armenian.*

BO′LUS BLESSE′NSIS. Bole of Blois. See *Bole.*

BO′LUS GA′LLICA. French bole. A pale red coloured bolar earth, variegated with irregular specks and veins of white and yellow. It is occasionally administered as an absorbent and antacid.

BOMBAX. See *Gossypium.*

BOMBIAS. A bombiate. A salt formed by the union of the bombic acid with different bases; thus *bombiate of alumine*, &c.

BO′MBIC ACID. *Acidum bombicum.* Acid of the silk-worm. Silk-worms contain, especially when in the state of chrysalis, an acid liquor in a reservoir placed near the anus. It is obtained by expressing their juice in a cloth, and precipitating the mucilage by spirit of wine, and likewise by infusing the chrysalides in that liquor. This acid is very penetrating, of a yellow amber colour, but its nature and combinations are not yet well known.

BO′MBUS. (Βομβος.) A resounding noise, or ringing of the ears. Also, a sonorous expulsion of flatus from the intestines.

BON A′RBOR. A name given to the coffee-tree.

BO′NA. *Boona.* The phaseolus, or kidney-bean.

BO′NDUCH INDO′RUM. See *Guilandina.*

BONE. *Os.* Bones are hard, dry, and insensible parts of the body, of a whitish colour, and composed of a spongy, compact, or recticular substance. They vary much in their appearances, some being long and hollow, others flat and compact, &c. The greater number of bones have several processes and cavities, which are distinguished from their figure, situation, use, &c. Thus processes extended from the end of a bone, if smooth and round, are called *heads;* and *condyles*, when flattened either above or laterally. That part which is beneath the head, and which exceeds the rest of the bone in smallness and levity, is called the neck. Rough, unequal processes are called *tuberosities* or tubercles: but the longer and more acute, *spinous* or *styloid* processes, from their resemblance to a thorn. Thin broad processes with sharp extremities, are known by the name of *cristæ*, or *sharp edges.* Other processes are distinguished by their form, and called *alar* or *pterygoid, mamillary* or *mastoid, dentiform* or *odontoid*, &c. Others, from their situation, are called *superior, inferior, exterior*, and *interior.* Some have their name from their direction, as *oblique, straight, transverse*, &c.; and some from their use, as *trochanters, rotators*, &c. *Furrows, depressions*, and *cavities*, are destined either for the reception of contiguous bones, to form an articulation with them, when they are called *articular cavities*, which are sometimes deeper, sometimes shallower; or they receive hard parts, but do not constitute a joint with them. Cavities serve also for the transmission and attachment of soft parts. Various names are given to them, according to the magnitude and figure of bones. If they be broad and large at the beginning, and not deep, but contracted at their ends, they are called *foveæ* or *pits.* Furrows are open canals, extending longitudinally in the surface of bones. A hollow, circular tube, for the most part of the same diameter from beginning to end, and more or less crooked or straight, long or short, is named a *canal. Foramina* are the apertures of canals, or they are formed of the excavated margins of two bones, placed against each other. If such be the form of the margin of a bone, as if a portion were taken out of it, it is called a *notch.*

With respect to the formation of bone, there have been various opinions. Physiologists of the present day assert that it is from a specific action of small arteries, by which ossific matter is separated from the blood, and deposited where it is required. The first thing observable in the embryo, where bone is to be formed, is a transparent *jelly*, which becomes gradually firmer, and is formed into *cartilage.* The cartilage gradually increases to a certain size, and when the process of ossification commences, vanishes as it advances. Cartilages, previous to the ossific action, are solid, and without any cavity; but when the ossific action of the arteries is about to commence, the absorbents become very active, and form a *small cavity* in which the bony matter is deposited; bone continues to be separated, and the absorbents model the mass into its required shape. The process of ossification is extremely rapid in utero: it advances slowly after birth, and is not completed in the human body till about the twentieth year. Ossification in the flat bones, as those of the skull, always begins from *central points*, and the radiated fibres meet the radii of other ossifying points, or the edges of the adjoining bone. In long bones, as those of the arm and leg, the clavicle, metacarpal, and metatarsal bones, a *central ring* is formed in the body of the bone, the head and extremities being cartilage, in the centre of which ossification afterwards begins. The central ring of the body shoots its bony fibres towards the head and extremities, which extend towards the body of the bone. The head and extremities at length come so close to the body as to be merely separated by a cartilage, which becomes gradually thinner until the twentieth year. Thick and round bones, as those of the tarsus, carpus, sternum, and patella, are, at first, all cartilage: ossification begins in the *centre* of each. When the bones are deprived of their soft parts, and are hung together in their natural situation, by means of wire, the whole is termed an *artificial* skeleton; but when they are kept together by means of their ligaments, it is called a *natural* skeleton. — The uses of the bones are various, and are to be found in the account of each bone; it is, therefore, only necessary to observe, in this place, that they give shape to the body, contain and defend the vital viscera, and afford an attachment to all the muscles.

A Table of the Bones.

				No.
Bones of the Head.	Bones of the *cranium* or *skull*		Frontal	1
			Parietal	2
			Occipital	1
			Temporal	2
			Ethmoid	1

Bones, growth of. See *Osteogeny.*

Bonebinder. See *Osteocolla.*

BONET, Theophilus, was born at Geneva in 1620, and graduated at Bologna. He had considerable practice, and was extremely zealous in the pursuit of morbid anatomy, as well as in extracting valuable observations from authors. His hearing becoming impaired, he devoted the latter part of his life to the arrangement of the materials, which he had prepared. His principal work, entitled "Sepulchretum," published 1679, was highly approved; and laid the foundation of Morgagni's excellent treatise, "De Sedibus et Causis Morborum." Another publication of his, "Mercurius compilatitius," is an index of medical literature to the time of its appearance, 1682. His death occurred seven years after.

Bononie'nsis la'pis. The Bononian-stone. Called also *phosphorus bononiensis, phosphorus kircheri*, the light carrier, or Bononian phosphorus. As a medicine the stone is caustic and emetic.

BONTIUS, James, was born at Leyden

where he studied medicine, and then went to practise in India. After his return, he wrote several valuable works on the diseases and practice of that country, as well as on its natural productions, animal and vegetable. The most esteemed is entitled " De Medicina Indorum," and appeared in 1642.

Bo′nus Henri′cus. (*Henricus;* so called because its virtues were detected by some one whose name was Henry.) See *Chenopodium.*

BORACIC ACID. *Acidum boracicum.* Sedative salt of Homberg. Acid of borax. Boracine acid. A concrete salt crystallized in small white scales, which may be obtained from borax, by adding concentrated sulphuric, nitric, muriatic, and even vegetable acids, to a hot solution of borax, till the lixivium becomes somewhat acid: the solution is then to be cooled, when the boracic acid will appear in the shape of bright scales. This acid, in combination with alkalies, earths, and metallic oxides, forms borates.

Bo′rage. See *Borago.*

BORA′GO. (Formerly written *Corago;* from *cor,* the heart, and *ago,* to affect; because it was supposed to comfort the heart and spirits.) Borage.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

2. The pharmacopœial name of the officinal borage. See *Borago officinalis.*

Bora′go officina′lis. The systematic name for the borage of the shops. *Buglossum verum. Buglossum latifolium. Borago hortensis.* The leaves and flowers of this plant, *Borago; foliis omnibus alternis, calycibus patentibus* of Linnæus, are esteemed in some countries as refrigerant and cordial. A syrup is prepared from the leaves in France, and used in pleurisies and inflammatory fevers. Their principal use in this island is in that grateful summer beverage, known by the name of cool tankard.

BO′RAS. A borate. A salt formed of boracic acid with an earthy, alkaline or metallic base: as borate of soda, &c.

Bo′ras so′dæ. Borate of soda. See *Borax.*

Bo′rate. See *Boras.*

BO′RAX. (*Borak,* Arab.) *Boras sodæ, sub-boras sodæ.* The obsolete synonyms are *Chrysocolla, capistrum auri, ancinar, boraxtrion, acestis anucar, antincar, tincal, amphitane, baurach, nitrum factitium, santerna,* and *nitrum nativum.* This salt, consisting of boracic acid united with soda, the soda being slightly in excess, is brought from Thibet and Persia, where it is found in a native state. This native or crude borax is called *tincal, tincor, boresh, pounxa,* in the East Indies, and was formerly purified in Europe by the Venetians, when it was called refined or Venetian borax; but it is now prepared by the Dutch by solution in hot water filtration, and careful crystallization. The particular process is not known. Its taste is cool: it is soluble in eighteen parts of cold and six of hot water. It is decomposed by several of the acids. Borax is rarely used internally in modern practice; and according to Murray it does not appear to possess any activity, although it is supposed by some to be, in doses of half a drachm or two scruples, diuretic and emmenagogue. It is occasionally given in cardialgia as an antacid. Its solution is in common use as a cooling gargle, and to detach mucus, &c. from the mouth in putrid fever; and mixed with an equal quantity of sugar, it is used in the form of powder to remove the aphthous crust from the tongue in children. The salts formed by the union of the acid of borax with different bases are called borates.

BORBORY′GMUS. (From βορβορυζω, to make a noise.) The rumbling noise occasioned by flatus in the intestines. It frequently precedes hysterical affections.

BORDEU, Theophilus de, a French physician, born in 1722. He graduated at Montpelier, and was soon after appointed inspector of the mineral waters at Bareges, and professor of anatomy. Subsequently he went to Paris, and was admitted to the faculty there in 1754. He died of apoplexy in his 55th year. His most esteemed work is on the cellular membrane; his distinctions of the pulse appear too nice for practical utility.

BORELLI, John Alphonsus, was born at Castelnuovo, in 1608. He first taught the mathematics in Sicily, then as professor at Pisa; and being soon after admitted to the celebrated academy del Cimento, he formed the design of explaining the functions of animal bodies on mathematical principles. For this purpose he applied himself diligently to dissection. His grand Work, " De Motu Animalium," was published after his death, which happened in 1679, at the expense of Christina, queen of Sweden. The imposing appearance of his opinions gained them many converts at first, but they have been found very defective on maturer examination. He was author of many other publications on different subjects.

Boro′zail. (Æthiop.) An epidemic disease of the Æthiopians, in appearanc similar to the lues venerea.

Borra′go. See *Borago.*

Bo′rri. (Indian.) *Borri-borri. Boberri.* The Indian name for turmeric; also an ointment used there, in which the roots of turmeric are a chief ingredient.

Bo′sa. An Egyptian word for a mass which is made of the meal of darnel, hempseed, and water. It is inebriating.

Bo′smoros. (From βοσκω, to eat, and μορος, a part: because it is divided for food by the mill.) *Bosporas.* A species of meal.

Bota′le fora′men. A name formerly applied to the foramen ovale.

BOTALLUS, Leonard, an eminent physician of Piedmont, flourished about the middle of the 16th century. He graduated at Padua; and attained considerable reputation, as well in surgery as in medicine; having the honour of attending two of the French kings, and the prince of Orange; the latter of whom he cured of a wound, in which the carotid artery had been injured. He published a treatise on gun-shot wounds, which long remained in high estimation. But that which chiefly gained him celebrity was a work on bleeding, general and local, which he recommended to be freely practised in a great variety of diseases, both acute and chronic. His opinions were adopted by many, and carried to an extravagant length, particularly in France: but more enlarged experience has tended greatly to lessen their prevalence.

BO′TANY. (*Botanica, βοτανικη*: from *βοτανη*, an herb or grass.) That part of natural history which considers every thing respecting the natural history of vegetables.

Bota′nicon. (From *βοτανη*, an herb.) A plaster made of herbs, and described by Paulus Ægineta.

Bo′thor. (Arab.) Tumours: pimples in the face: also the small-pox or measles.

Bo′thrion. (From *βοθριον*, a little pit.) *Botrium.* The alveolus or socket for the tooth: also an ulcerated cornea.

Bo′tia. A name given to scrophula.

Bo′tin. A name for turpentine.

Bo′tium. *Bocium.* Indurated bronchial glands.

Botothi′num. The most evident symptom of disease.

Botri′tis. (From *βοτρυς*, a bunch of grapes.) *Botryites.* A sort of burnt cadmia, collected in the top of the furnace, and resembling a bunch of grapes.

Bo′trys. (*βοτρυς*, a cluster of grapes; so called because its seeds hang down like a bunch of grapes.) The oak of Jerusalem.

Bo′trys mexica′na. See *Chenopodium ambrosioides.*

Bo′trys vulga′ris. See *Chenopodium botrys.*

Bo′tus. *Botia. Botus barbatus.* A cucurbit of the chemists.

Bouba′lios. See *Momordica Elaterium,* and *Pudendum muliebre.*

Bou bon. See *Bubo.*

BOUGI′E. (French for wax candle.) *Candela cerea. Candela medicata. Catheteres* of Swediaur. *Cerei medicati* of Le Dran. *Cereolus chirurgorum.* A term applied by surgeons to a long, slender instrument, that is introduced through the urethra into the bladder. Bougies made of the elastic gum are preferable to those made of wax. The caustic bougie differs from the ordinary one in having a thin roll of caustic in its middle, which destroys the stricture, or any part it comes in contact with. Those made of catgut are very seldom used, but are deserving of the attention of the surgeon. Bougies are chiefly used to overcome strictures in the urethra, and the introduction of them requires a good deal of address and caution. They should not be kept in the urethra so long at one time as to excite much pain or irritation. Before their use is discontinued, they should, if practicable, be carried the length of the bladder, in order to ascertain the extent of the strictures, taking care that this be performed not at once, but in a gradual manner, and after repeated trials; for much injury might arise from any hasty or violent efforts to remove the resistance that may present itself. There are bougies also for the œsophagus and rectum.

Bou′limus. (From *βου*, greatly, and *λιμος*, hunger; or from *βουλομαι*, to desire.) A canine or voracious appetite.

Bovi′llæ. (From *bos*, an ox, because cattle were supposed subject to it.) The measles.

Bovi′na fa′mes. The same as bulimia.

Bovi′sta. See *Lycoperdon.*

Box-tree. See *Buxus.*

Brache′rium. (From *brachiale*, a bracelet. A truss or bandage for hernia; a term used by the barbarous Latin writers.

Brachiæ′us mu′sculus. See *Brachialis internus.*

Brachiæ′us exte′rnus. See *Triceps extensor cubiti.*

Brachiæ′us inte′rnus. See *Brachialis internus.*

BRA′CHIAL A′RTERY. *Arteria brachialis.* The brachial artery is the continuation of the axillary artery, which, as it passes behind the tendon of the pectoralis major, receives the name of *brachial.* It runs down on the inside of the arm, over the musculus coraco-brachialis, and anconæus internus, and, along the inner edge of the biceps, behind the vena basilica, giving out small branches as it goes along. Below the bend of the arm it divides into the cubitalis and radialis. Sometimes, though rarely, the *brachial artery* is divided from its origin into two large branches, which run down on the arm, and afterwards on the fore-arm, where they are called *cubitalis* and *radialis.*

Brachia′le. The word means a bracelet; but the antient anatomical writers apply this term to the carpus, the part on which the bracelet was worn.

Brachia′lis. See *Brachialis internus.*

Brachia′lis exte′rnus. See *Triceps extensor cubiti.*

BRACHIA′LIS INTE′RNUS. *Brachiæus* of Winslow, *Brachiæus internus* of Cowper, and *Humero-cubital* of Dumas. A muscle of the fore-arm, situated on the fore part of the os humeri. It arises fleshy from the middle of the os humeri, at each side of the insertion of the deltoid muscle, covering all the inferior and fore-part of this bone, runs over the joint, and adheres firmly to the ligament; is inserted, by a strong short tendon, into the coronoid process of the ulna. Its use is to bend the fore-arm, and to prevent the capsular ligament of the joint from being pinched.

Brachio-cubital ligament. *Ligamentum brachio-cubitale.* The expansion of the lateral ligament, which is fixed in the inner condyle of the os humeri, runs over the capsular, to which it closely adheres, and is inserted like radii on the side of the great sigmoid cavity of the ulna; it is covered on the inside by several tendons, which adhere closely to it, and seem to strengthen it very considerably.

Brachio-radial ligament. *Ligamentum brachio-radiale.* The expansion of the lateral ligament, which runs over the external condyle of the os humeri, is inserted round the coronary ligament, from thence all the way down to the neck of the radius, and also in the neighbouring parts of the ulna. Through all this passage it covers the capsular ligament, and is covered by several tendons adhering closely to both.

Bra′chii os. See *Humeri os.*

BRA′CHIUM. (Βραχιον, the arm.) The arm, from the shoulder to the wrist.

Bra′chium mo′vens qua′rtus. See *Latissimus dorsi.*

Brachu′na. According to Avicenna, a species of furor uterinus.

Brachychro′nius. (From βραχυς, short, and χρονος, time.) A disease which continues but a short time.

Brachypnœ′a. (From βραχυς, short, and ϖνεω, to breathe.) Shortness and difficulty of breathing

Bra′chys. (From βραχυς, short.) A muscle of the scapula.

Bra′cium. Copper. Verdigris.

Bradype′psia. (From βραδυς, slow, and ϖεπτω, to concoct.) Weak digestion. See *Dyspepsia.*

Bra′ggat. A name formerly applied to a ptisan of honey and water.

Brain. See *Cerebrum.*

Brain, little. See *Cerebellum.*

BRAN. *Furfur.* The husks or shells of wheat, which remain in the boulting machine. It contains a portion of the farinaceous matter, and is said to have a laxative quality. Decoctions of bran, sweetened with sugar, are used by the common people, and sometimes with success, against coughs, hoarseness, &c.

Bra′nca. (*Branca*, Span. a foot, or branch.) A term applied to some herbs, which are supposed to resemble a particular foot; as *branca leonis*, lion's foot; *branca ursina*, bear's foot.

Bra′nca leoni′na. See *Alchemilla.*

Bra′nca ursi′na. See *Acanthus* and *Heracleum.*

Bra′nca leo′nis. See *Alchemilla.*

Bra′nchæ. (From βρεχω, to make moist.) *Branchi.* Swelled tonsils, or glandulous tumours, of the fauces, which secrete saliva.

Bra′nchus. (From βρεχω, to moisten.) A defluxion of humours from the fauces.

BRANDY. *Spiritus Gallicus.* A colourless, slightly opaque, and milky fluid, of a hot and penetrating taste, and a strong and agreeable smell, obtained by distilling from wine. It consists of water, ardent spirit, and a small portion of oil, which renders it milky at first, and, after a certain time, colours it yellow. It is the fluid from which rectified or ardent spirit is obtained. Its peculiar flavour depends on the nature of the volatile principles, or essential oil, which come over along with it in the distillation, and likewise, in some measure, upon the management of the fire, the wood of the cask in which it is kept, &c. It is said, that our rectifiers imitate the flavour of brandy, by adding a small proportion of nitrous ether to the spirit of malt, or molasses. The utility of brandy is very considerable, but, from its pleasant taste and exhilarating property, it is too often taken to excess. It gives energy to the animal functions; is a powerful tonic, cordial, and antispasmodic; and its utility with camphire, in gangrenous affections, is very great.

Branks. The name, in Scotland, for the mumps. See *Cynanche parotidæa.*

Brankursine. See *Acanthus.*

Brasi′lia. Brazil wood.

Brasilie′nse li′gnum. See *Hæmatoxylon.*

Brasilie′nsis ra′dix. The ipecacuanha root is sometimes so called.

Bra′sium. (From βρασσω, to boil.) Malt, or germinated barley.

Bra′sma. (From βρασσω, to boil.) The unripe black pepper. Fermentation.

Bra′smos. The same.

Brass. *Æs.* A combination of copper and zinc.

Brassade′lla. *Brassatella.* Ophioglossum, or the herb adder's tongue.

BRA′SSICA. (Varro says, *quasi præsica*; from *præseco*, to cut off; because it is cut from the stalk for use; or from ϖρασια, a bed in a garden where they are cultivated.) Crambe. Cabbage. Colewort. The name of a genus of plants in the Linnæan system.

Bra′ssica a′lba. The white cabbage.

Bra′ssica apia′na. Jagged or crimpled colewort.

Bra′ssica cani′na. The mercurialis sylvestris.

Bra′ssica capita′ta. Cabbage. There are several varieties of cabbage, all of which are generally hard of digestion, producing flatulencies, and afford very little nourishment. These inconveniences are not experienced by those whose stomachs are strong and accustomed to them. Few vegetables run into a state of putrefaction so quickly as cabbages; they ought, therefore, always to be used immediately after cutting. In Holland and Germany there is a method of preserving them, by cutting them into pieces, and sprinkling salt and some aromatic herbs among them; this mass is put into a tub, where it is pressed close, and left to ferment, when it is called *sour crout*, or *sauer kraut*. These, and all pickles of cabbage, are considered as wholesome and antiscorbutic, from the vinegar and spices they contain.

Bra'ssica congylo'des. Turnip cabbage.

Bra'ssica cuma'na. Red colewort.

Bra'ssica eru'ca. The systematic name for the plant which affords the semen erucæ. Garden rocket. Roman rocket. Rocket gentle. The seeds of this plant, *Brassica; foliis lyartis, caule hirsuto siliquis glabris*, of Linnæus, and of the wild rocket, have an acrid taste, and are eaten by the Italians in their pickles, &c. They are said to be good aperients and antiscorbutics, but are eesteemed by the above-mentioned people for their supposed aphrodisiac qualities.

Bra'ssica eruca'strum. *Eruca sylvestris.* Wild rocket. See *Brassica eruca.*

Bra'ssica flo'rida. Cauliflower. A variety of the oleracea.

Bra'ssica gonylico'des. Turnip cabbage.

Bra'ssica lacutu'rria. *Brassica lacuturris.* The savoy plant.

Bra'ssica mari'na. See *Convolvulus soldanella.*

Bra'ssica na'pus. The systematic name for the plant from which the *semen napi* is obtained. *Napus sylvestris. Bunias.* Wild navew, or rape. The seeds yield upon expression a large quantity of oil called rape oil, which is sometimes ordered in stimulating liniments.

Bra'ssica olera'cea. The systematic name for the *brassica capitata* of the shops. See *Brassica capitata.*

Bra'ssica ra'pa. The systematic name for the plant whose root is called turnip. *Rapum. Rapus. Napus. Napus dulcis.* The turnip. Turnips are accounted a salubrious food, demulcent, detergent, somewhat laxative and diuretic, but liable, in weak stomachs, to produce flatulencies, and prove difficult of digestion. The liquor pressed out of them, after boiling, is sometimes taken medicinally in coughs and disorders of the breast. The seeds are occasionally taken as diuretics; they have no smell, but a mild acrid taste.

Bra'ssica ru'bra. Red cabbage. Mr. Watt finds that the red cabbage affords a very excellent test both for acids and alkalies, in which it is superior to litmus, being naturally blue, turning green with alkalies, and red with acids.

Bra'ssica sati'va. The common garden cabbage.

Bra'ssica sabau'da. The savoy plant.

Brasside'llica ars. A way of curing wounds, mentioned by Paracelsus, by applying the herb *Brassidella* to them.

Bra'thu. (Βραθυ.) An old name for savine.

BREAD-FRUIT. The tree which affords this, grows in all the Ladrone Islands in the South sea, in Otaheite, and now in the West Indies. The bread-fruit grows upon a tree the size of a middling oak. The fruit is about the size of a child's head, and the surface is reticulated, not much unlike the surface of a truffle. It is covered with a thin skin, and has a core about the size of a small knife. The eatable part is between the skin and the core: it is as white as snow, and somewhat of the consistence of new bread. It must be toasted before it is eaten, being first divided into three or four parts. Its taste is insipid, with a slight sweetness, nearly like that of wheaten bread and artichoke together. This fruit is the constant food of the inhabitants all the year, it being in season eight months.

BREAST. *Mamma.* The two globular projections, composed of common integuments, adipose substance, and lacteal glands and vessels, and adhering to the anterior and lateral regions of the thorax of females. On the middle of each breast is a projecting portion, termed the *papilla* or *nipple*, in which the excretory ducts of the glands terminate, and around which is a coloured orb, or disc, called the *areola.* The use of the breasts is to suckle new-born infants.

Breast-bone. See *Sternum.*

Bre'gma. (From βρεχω, to moisten; formerly so called because, in infants, and sometimes even in adults, they are tender and moist.) An old name for the parietal bones.

Bre'via. (From *brevis*, short.) A specific name of some parts whose termination is not far from their origin, as *brevia vasa*, the branches of the splenic vein.

Bre'vis mu'sculus. A muscle of the scapula.

Bre'vis cu'biti. A muscle of the forearm.

Brévis exténsor digitórum pédis. See *Extensor brevis digitorum pedis.*

Brévis fléxor póllicis pédis. See *Flexor brevis pollicis pedis.*

Bre'vis perone'us. See *Peroneus brevis.*

Brévis pronátor rádii. See *Pronator radii quadratus.*

Brey'nia. (An American plant named in honour of Dr. Brennius.) A species of capparis.

Briar, wild. See *Rosa canina.*

Bri'cumum. A name which the Gauls gave to the herb artemisia.

Brimstone. See *Sulphur.*

BRISTOL HOT-WELL. *Bristoliensis aqua.* A pure, thermal or warm, slightly acidulated, mineral spring, situated about a mile below Bristol. The fresh water is inodorous, perfectly limpid, and sparkling, and sends forth numerous air bubbles when poured into a glass. It is very agreeable to the palate, but without having any very decided taste, at least none that can be distinguished by a common observer. Its specific gravity is only 1.00077, which approaches so near to that of distilled water, that this circumstance alone would shew that it contained but a very small admixture of foreign ingredients. The temperature of these waters, taking the average of the most accurate observations, may be reckoned at 74 deg.; and this does not very sensible vary during winter or summer. Bristol water contains both solid and gaseous matter, and the distinction between the two requires to be attended to, as it is owing to the very small quantity of solid matter that it deserves the character of a very fine natural spring; and to an excess in gaseous contents, that it seems to be principally indebted for its medical properties, whatever they may be, independent of those of mere water, with an increase of temperature. From the different investigations of chemists, it appears that the principal component parts of the Hotwell water, are a large proportion of carbonic acid gas, or fixed air, and a certain portion of magnesia and lime, in various combinations, with the muriatic, vitriolic, and carbonic acids. The general inference is, that it is considerably pure for a natural fountain, as it contains no other solid matter than is found in almost all common spring water, and in less quantity.

On account of these ingredients, especially the carbonic acid gas, the Hotwell water is efficacious in promoting salutary discharges, in green sickness, as well as in the blind hemorrhoids. It may be taken with advantage in obstructions, and weakness of the bowels, arising from habitual costiveness; and, from the purity of its aqueous part, it has justly been considered as a specific in diabetes, rendering the urinary organs more fitted to receive benefit from those medicines which are generally prescribed, and sometimes successful.

But the high reputation which this spring has acquired, is chiefly in the cure of pulmonary consumption. From the number of unsuccessful cases among those who frequent this place, many have denied any peculiar efficacy in this spring, superior to that of common water. It is not easy to determine how much may be owing to the favourable situation and mild temperate climate which Bristol enjoys; but it cannot be doubted that the Hotwell water, though by no means a cure for consumption, alleviates some of the most harassing symptoms of this formidable disease. It is particularly efficacious in moderating the thirst, the dry burning heat of the hands and feet, the partial night sweats, and the symptoms that are peculiarly hectical; and thus in the earlier stages of phthisis, it may materially contribute to a complete re-establishment of health; and even in the latter periods, mitigate the disease when the cure is doubtful, if not hopeless.

The sensible effects of this water, when drank warm and fresh from the spring, are a gentle glow of the stomach, succeeded sometimes by a slight and transient degree of headache and giddiness. By a continued use, in most cases it is diuretic, keeps the skin moist and perspirable, and improves the appetite and health. Its effects on the bowels are variable. On the whole, a tendency to costiveness seems to be the more general consequence of a long course of this medicinal spring, and therefore the use of a mild aperient is requisite. These effects, however, are applicable only to invalids, for healthy persons, who taste the water at the fountain, seldom discover any thing in it but a degree of warmth, which distinguishes it from the common element.

The season for the Hotwell is generally from the middle of May to October; but as the medicinal properties of the water continue the same throughout the year, the summer months are preferred merely on account of the concomitant benefits of air and exercise.

It should be mentioned, that another spring, nearly resembling the Hotwell, has been discovered at Clifton, which is situated on the summit of the same hill, from the bottom of which the Hotwell issues. The water of Sion-spring, as it is called, is one or two degrees colder than the Hotwell; but in other respects it sufficiently resembles it to be employed for all similar purposes.

Brita'nnica he'rba. See *Rumex hydrolapathum.*

British oil. A variety of the black species of petroleum, to which this name has been given as an empirical remedy.

Bro'ccoli. *Brassica Italica.* As an article of diet, this may be considered as more delicious than cauliflower and cabbage. Sound stomachs digest broccoli without any inconvenience; but in dyspeptic stomachs, even when combined with pepper, &c. it always produces flatulency, and nauseous eructations.

Brochos. (Βροχος, a snare.) A bandage.

Bro'chthus. (From βρεχω, to pour.) The throat; also a small kind of drinking-vessel.

Bro'chus. (Βροκος.) One with a prominent upper-lip, or one with a full mouth and prominent teeth.

BROCKLESBY, Richard, was born in Somersetshire, though of an Irish family, in 1722. After studying at Edinburgh, he graduated at Leyden; then settled in London, but did not advance very rapidly in practice. About 1757, he was appointed physician to the army in Germany, and on his return after six years, published the result of his experience, in a work entitled "Economical and Medical Observations." His success now became more decided, and being prudent in his affairs, and without a family, he realized a considerable fortune. He proved himself however sufficiently liberal, by presenting 1000l. to Mr. Edmund Burke, who had been his school-fellow; and by offering an annuity of 100l. to Dr. Johnson, to enable him to travel, which was not however accepted. He was author of several other works, and died in 1797.

Bro dium. A term in pharmacy, signifying the same with *jusculum*, broth, or the liquor in which any thing is boiled. Thus we sometimes read of *Brodium Salis*, or a decoction of salt.

BRO′MA. (From βρωσκω, to eat.) Food of any kind that is masticated, and not drank.

Broma-theon. (From βρωσκω, to eat.) Mushrooms.

BROMATO′LOGY. (*Bromatologia*: from βρωμα, food, and λογος, a discourse.) A discourse or treatise on food.

Brome′lia ana′nas. The systematic name of the plant which affords the *ananas* fruit, is the *Bromelia foliis ciliato-spinosis, mucronatis, spica comosa* of Linnæus. It is used principally as a delicacy for the table, and is also given with advantage as a refrigerant in fevers.

Brome lia kara′tas. The systematic name of the plant from which we obtain the fruit called penguin, which is given in the Spanish West Indies to cool and quench thirst in fevers, dysenteries, &c. It grows in a cluster, there being several of the size of one's finger together. Each portion is clothed with a husk, containing a white pulpy substance, which is the eatable part; and if it be not perfectly ripe, its flavour resembles that of the pine-apple. The juice of the ripe fruit is very austere, and is made use of to acidulate punch. The inhabitants of the West Indies make a wine of the penguin, which is very intoxicating, and has a good flavour.

BROMFEILD, William, was born in London, 1712; and attained considerable reputation as a surgeon. At the age of twenty-nine he began to give anatomical lectures, which were very well attended. About three years after, in conjunction with the Rev. Mr. Madan, he formed the plan of the Lock Hospital; and so ably enforced the advantages of such an institution, that a sufficient fund was raised for erecting the present building; and it has been since maintained by voluntary contributions. He was appointed surgeon, and held that office for many years: he was also surgeon to St. George's Hospital, and to Her Majesty's household. He wrote many works; the most considerable was entitled "Chirurgical Cases and Observations," in 1773, but reckoned not to answer the expectations entertained of him. He attained his eightieth year.

Bro′mion. (From βρωμος, the oat.) The name of a plaster, made with oaten flour, mentioned by Paulus Ægineta.

Bro′mus ste′rilis. (From βρωσκω, to eat.) The wild oat.

BRO′NCHIA. (*bronchia-orum*, neut. plur. From βρογχος, the throat.) See *Trachea*.

Bronchia′les arte′riæ. Bronchial arteries. Branches of the aorta given off in the chest.

Bronchia′les gla′ndulæ. Bronchial glands. Large blackish glands, situated about the bronchia and trachea, which secrete blackish mucus.

BRONCHOCE′LE. (From βρογχος, the windpipe, and κηλη, a tumour.) *Botium. Hernia gutturis. Guttur tumidum. Trachelophyma. Gossum. Exechebronchos. Gongrona. Hernia bronchialis. Tracheocele.* Derbyshire neck. This disease is marked by a tumour on the forepart of the neck, and seated between the trachea and skin. In general it has been supposed principally to occupy the thyroid gland. We are given to understand that it is a very common disorder in Derbyshire; but its occurrence is by no means frequent in other parts of Great Britain, or in Ireland. Amongst the inhabitants of the Alps, and other mountainous countries bordering thereon, it is a disease very often met with, and is there known by the name of goitre. The cause which gives rise to it, is by no means certain, and the observations of different writers are of very little practical utility. Dr. Saunders controverts the general idea of the bronchocele being produced by the use of snow water. The swelling is at first without pain, or any evident fluctuation; when the disease is of long standing, and the swelling considerable, we find it in general a very difficult matter to effect a cure by medicine, or any external application; and it might be unsafe to attempt its removal with a knife, on account of the enlarged state of its arteries, and its vicinity to the carotids; but in an early stage of the disease, by the aid of medicine a cure may be effected.

Although some relief has been obtained at times, and the disease probably somewhat retarded by external applications, such as blisters, discutient embrocations, and saponaceous and mercurial plasters, still a complete cure has seldom been effected without an internal use of medicine; and that which has always proved the most efficacious, is burnt sponge. The form under which this is most usually exhibited, is that of a lozenge. ℞. spongiæ ustæ ʒss. mucilag. Arab. gum. q. s. fiat trochiscus. When the tumour appears about the age of puberty, and before its structure has been too morbidly deranged, a pill consisting of a grain or two of calomel, must be given for three successive nights; and, on the fourth morning, a saline purge. Every night afterwards for three weeks, one of the troches should, when the patient is in bed, be put under the tongue, suffered to dissolve gradually, and the solution swallowed. The disgust at first arising from this remedy soon wears off. The pills and the purge are to be repeated at the end of three weeks, and the troches had recourse to as before; and this plan is to be pursued till the tumour is entirely dispersed. Some recommend the burnt sponge to be administered in larger doses. Sulphuretted potash dissolved in water, in the proportion of 30 grains to a quart daily, is a remedy which has been employed by Dr. Richter with success, in some cases, where calcined sponge failed. The sodæ subcarbonas being the basis of burnt sponge, is now frequently employed instead of it, and, indeed, it is a more active medicine.

BRONCHO′TOMY. (*Bronchotomia*; from *βρογχος*, the windpipe, and *τεμνω*, to cut.) Tracheotomy. Laryngotomy. This is an operation in which an opening is made into the larynx, or trachea, either for the purpose of making a passage for the air into and out of the lungs, when any disease prevents the patient from breathing through the mouth and nostrils, or of extracting foreign bodies, which have accidentally fallen into the trachea; or, lastly, in order to be able to inflate the lungs, in cases of sudden suffocation, drowning, &c. Its practicableness, and little danger, are founded on the facility with which certain wounds of the windpipe, even of the most complicated kind, have been healed, without leaving any ill effects whatever, and on the nature of the parts cut, which are not furnished with any vessel of consequence.

Bro′nchos. (Βρογχος, the windpipe.) A catarrh; a suppression of the voice from a catarrh.

Bro′nchus. (From *βρεχω*, to pour.) The windpipe. The antients believed that the solids were conveyed into the stomach by the œsophagus, and the fluids by the bronchia; whence its name.

Brooklime Speedwell. See *Veronica beccabunga.*

Broom, common. See *Spartiumscoparium.*

BROWN, John, born in the county of Berwick, in 1735. He made very rapid progress in his youth in the learned languages, and at the age of twenty went to Edinburgh to study theology; but before he could be ordained, became attached to free-living and free-thinking. About 1759 having translated the inaugural thesis of a medical candidate into Latin, and the performance being highly applauded, he was led to the study of medicine. The professors at Edinburgh allowed him to attend their lectures gratuitously; and he maintained himself by instructing the students in Latin, and composing or translating their dissertations. Dr. Cullen particularly encouraged him, notwithstanding his irregularities, employing him as tutor to his sons, and allowing him to repeat and enlarge upon his lectures in the evening to those pupils, who chose to attend. In 1765 he married, and his house was soon filled with boarders; but his imprudence brought on bankruptcy within four years after. About this period he was an unsuccessful candidate for one of the medical chairs; and attributing his failure to Dr Cullen, became his declared enemy. This probably determined him to form his new system of medicine, afterwards published under the title of "Elementa Medicinæ:" in which certainly much genius is displayed, but little acquaintance with practice, or with what had been written before on the subject. His chief object seems to have been to reduce the medical art to the utmost simplicity: whence he arranged all diseases under the two divisions of sthenic and asthenic, and maintained that all agents operate on the body as stimuli; so that we had only to increase or diminish the force of these according to circumstances. At the head of his stimulant remedies he places wine, brandy, and opium; in the recommendation of which he is very liberal: and especially betrays his partiality to them by asserting, contrary to universal experience, that he found them in his own person the best preservatives against the gout. He is said to have prepared himself for his lectures by a large dose of laudanum in whisky; and thus roused himself to a degree of enthusiasm, bordering on frenzy. After completing his work, he procured a degree from St. Andrew's, and commenced public teacher. The novelty and imposing simplicity of his doctrines procured him at first a pretty numerous class: but being irregular in his attendance, and his habits of intemperance increasing, they fell off by degrees: and he was at length so embarrassed, as to be obliged to quit Edinburgh in 1786. He then settled in London, but met with little success, and in about two years after died. His opinions at first found many supporters as well in this as in other countries; but they appear now nearly fallen into deserved oblivion.

BROWNE, Sir Thomas, was born in Cheapside, 1605. After studying and practising for a short time at Oxford, he spent about three years in travelling, graduating at length at Leyden. He then came to London, and published his "Religio Medici;" which excited great attention as a work of genius, though blemished by a few of the popular superstitions then prevailing. He soon after settled at Norwich, and got into very good practice; and was admitted an honorary member of the London College of physicians. In 1646 appeared his most popular work "On Vulgar Errors," which added greatly to his fame; though he injudiciously ranked the Copernican system among them. He was knighted by Charles II.; and died at the termination of his 77th year. His son Edward was also a physician, and attained considerable eminence, having had the honour of attending Charles II. and William III., and being for three years president of the college.

BRU'CEA. (So named by Sir Joseph Banks, in honour of Mr. Bruce, the traveller in Abyssinia, who first brought the seeds thence into England.) The name of a genus of plants in the Linnæan system.

BRU'CEA ANTIDYSENTE'RICA. The systematic name of the plant from which it was erroneously supposed we obtained the angustura bark. See *Cusparia.*

BRU'CEA FERRUGI'NEA. This plant was also supposed to afford the angustura bark.

Bruisewort. See *Saponaria.*

BRUNE'LLA. See *Prunella.*

BRUNNER, JOHN CONRAD, was born in Switzerland in 1653. He obtained his degree in medicine at Strasburg when only nineteen. He afterwards spent several years in improving himself at different universities, particularly at Paris; where he made many experiments on the pancreas, and found that it might be removed from a dog with impunity. On his return he was made professor of medicine at Heidelberg; and gained great reputation, so as to be consulted by most of the princes of Germany. He discovered the mucous glands in the duodenum; and was author of several inconsiderable works. He died in 1727.

BRU'NNER'S GLANDS. *Brunneri glandulæ.* Peyer's glands. The muciparous glands, situated between the villous and cellular coat of the intestinal canal; so named after Brunner, who discovered them.

BRU'NUS. An erysipelatous eruption.

BRU'SCUS. See *Ruscus.*

BRU'TA. (Arab.) Instinct. Savine.

BRU'TIA. An epithet for the most resinous kind of pitch, therefore used to make the *Oleum Picinum.* The *Pix Brutia* was so called from Brutia, a country in the extreme parts of Italy, where it was produced.

BRUTI'NO. Turpentine.

BRU'TOBON. The name of an ointment used by the Greeks.

BRUTUA. See *Cissampelos Pareira.*

BRUXANE'LI. (Indian.) A tall tree in Malabar, whose bark is diuretic, according to Ray.

BRY'GMUS. (From *βρυχω*, to make a noise.) A peculiar kind of noise, such as is made by gnashing or grating the teeth; or, according to some, a certain kind of convulsion affecting the lower jaw, and striking the teeth together, most frequently observed in such children as have worms.

BRYO'NIA. (From *βρυω*, to abound, from its abundance.) Bryony.

1. The name of a genus of plants in the Linnæan system. Class, *Diœcia.* Order, *Syngenesia.*

2. The pharmacopœial name of the white bryony. See *Bryonia alba.*

BRYO'NIA A'LBA. The systematic name of the white bryony plant. *Vitis alba sylvestris. Agrostis. Ampelos. Archeostris. Echetrosis* of Hippocrates. *Bryonia aspera. Cedrostis. Chelidonium. Labrusca. Melothrum. Ophrostaphylon. Psilothrum. Bryonia; foliis palmatis utrinque calloso-scabris* of Linnæus. This plant is very common in woods and hedges. The root has a very nauseous biting taste, and disagreeable smell. Bergius states the virtues of this root to be purgative, hydragogue, emmenagogue, and diuretic; the fresh root emetic. This powerful and irritating cathartic, though now seldom prescribed by physicians, is said to be of great efficacy in evacuating serous humours, and has been chiefly employed in hydropical cases. Instances of its good effects in other chronic diseases are also mentioned, as asthma, mania, and epilepsy. In small doses, it is reported to operate as a diuretic, and to be resolvent and deobstruent. In powder, from ℈j. to a drachm, it proves strongly purgative; and the juice, which issues spontaneously, in doses of a spoonful or more, has similar effects, but is more gentle in its operation. An extract prepared by water, acts more mildly, and with greater safety than the root in substance, given from half a drachm to a drachm. It is said to prove a gentle purgative, and likewise to operate powerfully by urine. Of the expressed juice, a spoonful acts violently both upwards and downwards; but cream of tartar is said to take off its virulence. Externally, the fresh root has been employed in cataplasms, as a resolvent and discutient: also in ischiadic and other rheumatic affections.

BRYO'NIA MECHOACHA'NA NI'GRICANS. A name given to the jalap root.

BRYO'NIA NI'GRA. Black bryony, or vine. The *Tamus communis* of Linnæus.

BRYO'NIA PERUVIA'NA. Jalap.

Bry'ony, black. See *Bryonia nigra.*

Bry'ony, white. See *Bryonia.*

BRY'THION. (Βρυθιον.) A malagma so called, and described by Paulus Ægineta.

BRY'TON. (From *βρυω*, to pour out.) A kind of ale, or wine, made of barley.

BUBASTECO'RDIUM. (From *bubastus* and *cor*, the heart.) A name formerly given to artemisia, or mugwort.

BU'BO. (From *βουϐων*, the groin; because they most frequently happen in that part.) Modern surgeons mean, by this term, a swelling of the lymphatic glands, particularly of those of the groin and axilla. The disease may arise from the mere irritation of some local disorder, when it is called *sympathetic bubo;* from the absorption of some irritating matter, such as the venereal poison; or from constitutional causes, as in the pestilential bubo, and scrophulous swellings, of the inguinal and axillary glands.

BUBON. (From βουβων, the groin, or a tumour to which that part is liable, and which it was supposed to cure.) The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.*

Bu'bon ga'lbanum. The systematic name of the plant which affords the officinal galbanum. *Albetad. Chalbane. Gesor.* The plant is also named *Ferula Africana; Oreoselinum Africanum; Anisum fruticosum galbaniferum; Anisum Africanum frutescens;* and *Ayborzat.* Galbanum is the gummi-resinous juice, obtained partly by its spontaneous exudation from the joints of the stem of the Lovage-leaved bubon, *Bubon; foliis rhombeis dentatis striatis glabris, umbellis paucis,* of Linnæus: but more generally, and in greater abundance, by making an incision in the stalk, a few inches above the root, from which it immediately issues, and soon becomes sufficiently concrete to be gathered. It is imported into England from Turkey and the East Indies, in large, softish, ductile, pale-coloured masses, which, by age, acquire a brownish-yellow appearance: these are intermixed with distinct whitish tears, that are the most pure part of the mass. Galbanum has a strong unpleasant smell, and a warm, bitterish, acrid taste. Like the other gummy resins, it unites with water, by trituration into a milky liquor, but does not perfectly dissolve, as some have reported, in water, vinegar, or wine. Rectified spirit takes up much more than either of these menstrua, but not the whole: the tincture is of a bright golden colour. A mixture of two parts of rectified spirit, and one of water, dissolves all but the impurities, which are commonly in considerable quantity. In distillation with water, the oil separates and rises to the surface, in colour yellowish, in quantity one-twentieth of the weight of the galbanum. Galbanum, medicinally considered, may be said to hold a middle rank between assafœtida and ammoniacum; but its fœtidness is very inconsiderable, especially when compared with the former: it is therefore accounted less antispasmodic, nor are its expectorant qualities equal to those of the latter; it however is esteemed more efficacious than either in hysterical disorders. Externally, it is often applied, by surgeons, to expedite the suppuration of inflammatory and indolent tumours, and, by physicians, as a warm stimulating plaster. It is an ingredient in the *pilulæ galbani compositæ,* the *emplastrum galbani compositum* of the London Pharmacopœia, and in the *emplastrum gummosum* of the Edinburgh.

Bu'bon macedo'nicum. The systematic name of the plant which affords the *semen petroselini Macedonici* of the shops. *Apium petræum. Petrapium.* Macedonian parsley. This plant, *Bubon Macedonicum* of Linnæus, is similar in quality to the common parsley, but weaker and less grateful. The seeds enter the celebrated compounds mithridate and theriaca.

Bubo'nium. (From βουβων, the groin.) A name of the golden starwort; so called because it was supposed to be efficacious in diseases of the groin.

BUBONOCE'LE. (From βουβων, the groin, and κηλη, a tumour.) *Hernia inguinalis.* Inguinal hernia, or rupture of the groin. A species of hernia, in which the bowels protrude, at the abdominal ring. See *Hernia.*

Bu'cca. (Heb.) The cheek. The hollow inner part of the cheek, that is inflated by the act of blowing.

Buccacra'ton. (From *bucca,* or *buccella,* and κραω, to mix; that is, a morsel of bread sopped in wine, which served in old times for a breakfast.)

Bu'ccal glands. (*Glandulæ buccinales:* from *bucca,* the cheek.) The small glands of the mouth, under the cheek, which assist in secreting saliva into that cavity.

Bu'ccea. (From *bucca,* the cheek; as much as can be contained at one time within the cheeks.) A mouthful; a morsel; a polypus of the nose.

Buccela'ton. (From *buccella,* a morsel.) A purging medicine, made up in the form of a loaf; consisting of scammony, &c. put into fermented flour, and then baked in an oven.

Bucce'lla. Paracelsus calls by the name of *Buccella,* the carneous excrescence of the polypus in the nose, because he supposes it to be a portion of flesh parting from the bucca, and insinuating itself into the nose. See *Buccea.*

Buccella'tio. (From *buccellatus,* cut into small pieces.) *Bucelatio.* A method of stopping an hemorrhage, by applying small pieces of lint to the vein, or artery.

BUCCINA'TOR. (*Musculus buccinator.* So named from its use in forcing the breath to sound the trumpet; from βουκανον, a trumpet.) *Retractor anguli oris* of Albinus, and *alveolo-maxillaire* of Dumas. The trumpeter's muscle. The buccinator was long thought to be a muscle of the lower jaw, arising from the upper alveoli, and inserted into the lower alveoli, to pull the jaw upwards; but its origin and insertion, and the direction of its fibres, are quite the reverse of this. For this large flat muscle, which forms in a manner the walls of the cheek, arises chiefly from the coronoid process of the lower jaw-bone, and partly also from the end of the alveoli, or socket process of the upper-jaw, close by the pterygoid process of the sphenoid bone: it goes forward, with direct fibres, to be implanted into the corner of the mouth; it is thin and flat, covers in the mouth, and forms the walls of the cheek, and is perforated in the middle of the cheek by the duct of the parotid gland. These are its principal uses: — it flattens the cheek, and so assists in swallowing liquids; — it turns, or helps to turn, the morsel in the mouth, while chewing, and prevents it from getting without the line of the teeth; — in blowing wind-instruments, it both receives and expels the wind; — it dilates like a bag, so as to receive the wind in the cheeks; and it contracts upon the wind, so as to expel the wind, and to swell the note. In blowing the strong wind-instruments, we cannot blow from the lungs, for it distresses the breathing, we reserve the air in the mouth, which we keep continually full; and from this circumstance, as mentioned above, it is named buccinator, from blowing the trumpet.

Bu′ccula. (Dim. of *bucca,* the cheek.) The fleshy part under the chin.

Buce′phalon, red-fruited. The plant so called, is the *Trophis Americana* of Linnæus. Its fruit is a kind of rough red berry, which is eaten by the inhabitants of Jamaica, although its flavour is by no means pleasant.

Bu′ceras. (From *βους*, an ox, and *κερας*, a horn; so called from the horn-like appearance of its seed.) *Buceros.* Fenugreek seed. See *Trigonella Fœnumgræcum.*

BUCHAN, William, was born at Ancram, in 1729. After studying at Edinburgh, he settled in Sheffield, and was soon appointed physician to the Foundling Hospital at Ackworth: but that establishment being afterwards given up, he went to practise at Edinburgh, where he remained several years. During that period he composed his celebrated Work, called "Domestic Medicine," on the plan of Tissot's "Avis aux Peuples;" which has been very extensively circulated, translated into other languages, and obtained the author a gold medal, with a commendatory letter, from the Empress of Russia. It has been objected, that such publications tend to degrade and injure the medical profession; but it does not appear that those, who are properly qualified, can suffer permanently thereby. There seems more foundation for the opinion, that imaginary diseases will be multiplied, and patients sometimes fall victims to their complaints, being treated by those, who do not properly understand them. Dr. Buchan afterwards practised in London, and published some other works; and died in 1805.

Buck-bean. See *Menyanthes trifoliata.*

Buck-thorn. See *Rhamnus catharticus.*

Buck-wheat. See *Polygonum fagopyrum.*

Buck-wheat, eastern. See *Polygonum divaricatum.*

Bucra′nion. (From *βους*, an ox, and *κρανιον*, the head; so called from its supposed resemblance to a calf's snout.) The antirrhinum, or snap-dragon plant.

Bu′cton. The hymen, according to Piræus.

Buga′ntia. Chilblains.

Bugle. See *Prunella.*

Bugloss. See *Anchusa officinalis.*

BUGLO′SSUM. (From *βους*, an ox, and *γλωσσα*, a tongue; so called from the shape and roughness of its leaf.) See *Anchusa officinalis.*

Buglo′ssum sylve′stre. The stone bugloss.

Bu′gula. (A dim. of *buglossa.*) See *Ajuga pyramidalis.*

BULBOCA′STANUM. (From *βολϐος*, a bulb, and *καϛανον*, a chesnut; so called from its bulbous appearance.) See *Bunium bulbocastanum.*

Bulbocaverno′sus. (*Bulbocavernosus,* sc. *musculus:* so called from its origin and insertion.) See *Accelerator urinæ.*

Bu′lbonach. (Germ.) The *Lunaria rediviva* of Linnæus. Satin and honesty. It is said, by Ray, to be a warm diuretic.

Bu′lbus escule′ntus. Such bulbous roots as are commonly eaten are so called.

Bu′lbus vomito′rius. *Muscari. Hyacinthus muscari* of Linnæus. Musk-Grape-flower. Emetic and diuretic, according to Ray.

Bulge-water-tree. The *Geoffroya Jamaicensis.*

BULI′MIA. (From *βου*, a particle of excess, and *λιμος*, hunger.) *Bulimiasis. Boulimos. Bulimus. Bolismos* of Avicenna. *Fames canina. Appetitus caninus. Phagedæna. Adephagia. Bupeina. Cynorexia.* Insatiable hunger, or canine appetite.

Dr. Cullen places this genus of disease in the class *locales,* and order *dysorexiæ;* and distinguishes three species. 1. *Bulimia helluonum;* in which there is no other disorder of the stomach, than an excessive craving of food. 2. *Bulimia syncopalis;* in which there is a frequent desire of food, and the sense of hunger is preceded by swooning. 3. *Bulimia emetica,* also *cynorexia;* in which an extraordinary appetite for food is followed by vomiting. The real causes of this disease are, perhaps, not properly understood. In some cases, it has been supposed to proceed from an acid in the stomach, and in others, from a superabundance of acid in the gastric juice, and from indigested sordes, or worms. Some consider it as depending more frequently on monstrosity than disease. An extraordinary and well-attested case of this disease, is related in the third volume of the Medical and Physical Journal, of a French prisoner, who, in one day, consumed of raw cow's udder 4 lbs., raw beef 10 lbs., candles 2 lbs.; total, 16 lbs.; besides 5 bottles of porter.

Buli′mia addepha′gia. A voracious appetite.

Buli′mia cani′na. A voracious appetite, with subsequent vomiting.

Buli′mia cardia′lgica. A voracious appetite, with heartburn.

Buli′mia convulso′rum. A voracious appetite, with convulsions.

Buli′mia eme′tica. A voracious appetite, with vomiting.

Buli′mia helluo′num. Gluttony.

Buli′mia esuri′gio. Gluttony.

Buli′mia syncopa′lis. A voracious appetite, with fainting, from hunger.

Buli′mia vermino′sa. A voracious appetite, from worms.

Bulimi′asis. See *Bulimia*.

Bu′limus. See *Bulimia*.

Buli′thum. (From βους, an ox, and λιθος, a stone.) A bezoar, or stone, found in the kidneys, or gall, or urinary bladder, of an ox, or cow.

Bu′lla. (A bubble.) A clear vesicle, which arises from burns, or scalds; or other causes.

Bu′llace. The fruit so called, is the produce of the *Prunus insitia* of Linnæus, which grows wild in our hedges. There are two varieties of bullace, the red and the white, which are used with the same intentions as the common damsons.

Bullo′sa fe′bris. An epithet applied to the vesicular fever, because the skin is covered with little vesicles, or blisters. See *Pemphigus*.

Buni′tes vi′num. (From *bunium*, wild parsley.) A wine made of bunium and must.

BU′NIUM. (From βουνος, a little hill; so called from the tuberosity of its root.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Digynia*.

2. The name of the wild parsley.

Bu′nium Bulboca′stanum. The systematic name of a plant whose root is called the pig-nut. *Agriocastanum*. *Nucula terrestris*. *Bulbocastaneum*. *Bulbocastanum majus et minus*. Earth-nut. Hawk-nut. Kipper-nut, and pig-nut. The root is as large as a nutmeg; hard, tuberous, and whitish; which is eaten raw, or roasted. It is sweetish to the taste, nourishing, and supposed to be of use against strangury and bloody urine.

Bu′nius. A species of turnip.

Bupei′na. (From βου, a particle of magnitude, and ϖεινα, hunger.) A voracious appetite.

Bu′phagos. (From βου, a particle of excess, and φαγω, to eat.) The name of an antidote which created a voracious appetite in Marcellus Empiricus.

Buphtha′lmum. (From βους, an ox, and οφθαλμος, an eye; so called from its flowers, which are supposed to resemble an eye.) The herb ox-eye daisy. See *Chrysanthemum leucanthemum*.

Buphtha′lmum cre′ticum. Pellitory of Spain. See *Anthemis Pyrethrum*.

Buphtha′lmum Germa′nicum. The common ox-eye daisy.

Buphtha′lmum ma′jus. Great, or ox-eye daisy. See *Chrysanthemum leucanthemum*.

Buphtha′lmus. (From βους, an ox, and οφθαλμος, an eye; so named from its large appearance, like an ox's eye.)

1. Diseased enlargement of the eye.

2. Houseleek.

BUPLEU′RUM. (From βου, large, and ϖλευρον, a rib; so named from its having large rib-like filaments upon its leaves.)

1. The name of a genus of plants in the Linnæan system.

2. The pharmacopœial name of the herb hare's ear.

Bupleu′rum rotundifo′lium. The systematic name of the plant called perfoliata, in some pharmacopœias. *Bupleuron*. *Bupleuroides*. Round-leaved hare's ear, or thorow wax. This plant, *Bupleurum rotundifolium* of Linnæus, was formerly celebrated for curing ruptures, mixed into a poultice with wine and oatmeal.

Búrdock. See *Arctium Lappa*.

Búrgundy pitch. See *Pinus Abies*.

Bu′rac. (Arab.) Borax. It also means any kind of salt.

Bu′ris. According to Avicenna, a scirrhous hernia, or hard abscess.

BURN, or Scald, denotes a lesion of the animal body, occasioned by the application of heat, but the latter term is applicable only where this is conveyed through the medium of some fluid. The consequences are more or less serious according to the extent of the injury, or the particular part affected: sometimes even proving fatal, particularly in irritable constitutions. The life of the part may be at once destroyed by these accidents, or mortification speedily follow the violent inflammation excited; but when slighter, it usually produces an effusion of serum under the cuticle, like a blister. When the injury is extensive, considerable fever is apt to supervene, sometimes a comatose state; and a remarkable difficulty of breathing often precedes death. In the treatment of these accidents, two very different methods have been pursued. The more ancient plan consists in antiphlogistic means, giving cooling purgatives, &c. and even taking blood, where the irritation is great; employing at the same time cold applications, and where the skin is destroyed emollient dressings; opium was also recommended to relieve the pain, notwithstanding stupor might attend. Mr. Cleghorn, a brewer at Edinburgh, was very successful in these cases by a treatment materially different; first bathing the part with vinegar, usually a little warmed, till the pain abated; then, if there were any destruction of parts, applying poultices, and finely powdered chalk immediately on the sore, to absorb the discharge: in the mean time allowing the patient to live pretty well, and abstaining from active purgatives, &c. More recently, a surgeon at Newcastle of the name of Kentish, has deviated still more from the ancient practice; applying first oil of turpentine, alkohol, &c. heated as much as the sound parts could bear, and gradually lessening the stimulus; in the mean time supporting the patient by a cordial diet, æther, &c. and giving opium largely to lessen the irritation. Now the cases chiefly under his care were of persons scorched very extensively by the explosion of carburetted hydrogen in mines; and probably where the injury is over a large part of the surface, or where the constitution is weakly, it may be hazardous to pursue the antiphlogistic plan, or to use cold applications, which, while intended to keep down action, are wearing out the power of the part. If any extraneous substance be forced into the burnt part, it should be of course removed: and sometimes where a limb is irrecoverably injured, amputation may be necessary.

Bu'rnea. Pitch.

Burnet saxifrage. See *Pimpinella.*

Burning. *Brenning.* An antient medical term, denoting an infectious disease, got in the stews by conversing with lewd women, and supposed to be the same with what we now call the venereal disease.

Bu'rrhi spi'ritus matrica'lis. Burrhus's spirit, for disorders of the womb. A compound of myrrh, olibanum, amber, and spirit of wine.

Burnt hartshorn. See *Cornu ustum.*

Burnt sponge. See *Spongia usta.*

Bu'rsa. A bag.

1. The scrotum.

2. A herb called *Thlaspi bursæ pastoris,* from the resemblance of its seminal follicles to a triangular purse.

BURSA'LOGY. (From βυρσα, a bag, and λογος, a discourse.) The doctrine of the bursæ mucosæ.

BU'RSÆ MUCO'SÆ. Mucous bags, composed of proper membranes, containing a kind of mucous fat, formed by the exhaling arteries of the internal coat. They are of different sizes and firmness, and are connected by the cellular membrane with articular cavities, tendons, ligaments, or the periosteum. The use of the bursæ mucosæ is to secrete, and contain a substance to lubricate tendons, muscles, and bones, in order to render their motion easy.

A Table of all the Bursæ Mucosæ.

In the Head.

1. *A bursa of the superior oblique muscle* of the eye, situated behind its trochlea in the orbit.

2. *The bursa of the digastricus,* situated in the internal surface of its tendon.

3. *A bursa of the circumflexus,* or tensor palati, situated between the hook-like process of the sphenoid bone and the tendon of that muscle.

4. *A bursa of the sterno-hyoideus muscle,* situated between the os hyoides and larynx.

About the Shoulder-joint.

1. *The external acromial,* situated under the acromion, between the coracoid process, deltoid muscle, and capsular ligament.

2. *The internal acromial,* situated above the tendon of the infra-spinatus and teres major: it often communicates with the former.

3. *The coracoid bursa,* situated near the root of the coracoid process; it is sometimes double and sometimes triple.

4. *The clavicular bursa,* found where the clavicle touches the coracoid process.

5. *The subclavian bursa,* between the tendon of the subclavius muscle and the first rib.

6. *The coraco-brachial,* placed between the common origin of this muscle and the biceps, and the capsular ligament.

7. *The bursa of the pectoralis major,* situated under the head of the humerus, between the internal surface of the tendon of that muscle and another bursa placed on the long head of the biceps.

8. *An external bursa of the teres major,* under the head of the os humeri, between it and the tendon of the teres major.

9. *An internal bursa of the teres major,* found within the muscle where the fibres of its tendon diverge.

10. *A bursa of the latissimus dorsi,* between the tendon of this muscle and the os humeri.

11. *The humero-bicipital bursa,* in the vagina of the tendon of the biceps.

There are other bursæ mucosæ about the humerus, but their situation is uncertain.

Near the Elbow-joint.

1. *The radio-bicipital,* situated between the tendon of the biceps, brachialis, and anterior tubercle of the radius.

2. *The cubito-radial,* between the tendon of the biceps, supinator brevis, and the ligament common to the radius and ulna.

3. *The anconeal bursa,* between the olecranon and tendon of the anconeus muscle.

4. *The capitulo-radial bursa,* between the tendon common to the extensor carpi radialis brevis, and extensor communis digitorum and round head of the radius. There

are occasionally other bursæ, but as their situation varies, they are omitted.

About the inferior part of the Fore-arm and Hand.

On the inside of the Wrist and Hand.

1. A *very large bursa*, for the tendon of the flexor pollicis longus.

2. *Four short bursæ* on the fore-part of the tendons of the flexor sublimis.

3. *A large bursa* behind the tendon of the flexor pollicis longus, between it and the fore-part of the radius, capsular ligament of the wrist and os trapezium.

4. *A large bursa* behind the tendons of the flexor digitorum profundus, and on the fore-part of the end of the radius, and fore-part of the capsular ligament of the wrist. In some subjects it communicates with the former.

5. *An oblong bursa* between the tendon of the flexor carpi radialis and os trapezium.

6. *A very small bursa* between the tendon of the flexor carpi ulnaris and os pisiforme.

On the back part of the Wrist and Hand.

7. *A bursa* between the tendon of the abductor pollicis longus and the radius.

8. *A large bursa* between the two extensores carpi radiales.

9. *Another* below it, common to the extensores carpi radiales.

10. *A bursa*, at the insertion of the tendon of the extensor carpi radialis.

11. *An oblong bursa*, for the tendon of the extensor pollicis longus, and which communicates with 9.

12. *A bursa*, for the tendon of the extensor pollicis longus, between it and the metacarpal bone of the thumb.

13. *A bursa* between the tendons of the extensor of the fore, middle, and ring fingers.

14. *A bursa* for the extensors of the little finger.

15. *A bursa* between the tendon of the extensor carpi ulnaris and ligament of the wrist.

There are also bursæ mucosæ between the musculi lumbricales and interossei.

Near the Hip-joint.

On the fore-part of the joint.

1. *The ileo-puberal*, situated between the iliacus internus, psoas magnus, and the capsular ligament of the head of the femur.

2. *The pectineal*, between the tendon of the pectineus and the thigh-bone.

3. *A small bursa* of the gluteus medius muscle, situated between it and the great trochanter, before the insertion of the pyriformis.

4. *A bursa* of the gluteus minimus muscle between its tendon and the great trochanter.

5. *The gluteo-fascial*, between the gluteus maximus and vastus externus.

On the posterior part of the Hip-joint.

6. *The tubero-ischiatic bursa*, situated between the obturator internus muscle, the posterior spine of the ischium, and its tuberosity.

7. *The obturatory bursa*, which is oblong, and found between the obturator internus and gemini muscles, and the capsular ligament.

8. *A bursa of the semi-membranosus*, under its origin and the long head of the biceps femoris.

9. *The gluteo trochanteral bursa*, situated between the tendon of the psoas muscle and the root of the great trochanter.

10. *Two gluteo-femoral bursæ*, situated between the tendon of the gluteus maximus and os femoris.

11. *A bursa of the quadratus femoris*, situated between it and the little trochanter.

12. *The iliac bursa*, situated between the tendon of the iliacus internus and the little trochanter.

Near the Knee-joint.

1. *The supra-genual*, which adheres to the tendons of the vastus and cruralis and the fore-part of the thigh-bone.

2. *The infra-genual bursa*, situated under the ligament of the patella, and often communicating with the above.

3. *The anterior genual*, placed between the tendon of the sartorius, gracilis, and semitendinosus and the internal and lateral ligament of the knee.

4. *The posterior genual*, which is sometimes double, and is situated between the tendons of the semi-membranosus, the internal head of the gastrocnemius, the capsular ligament, and internal condyle.

5. *The popliteal*, conspicuous between the tendon of that muscle, the external condyle of the femur, the semilunar cartilage, and external condyle of the tibia.

6. *The bursa of the biceps cruris*, between the external part of the tendon, the biceps cruris, and the external lateral ligament of the knee.

In the Foot.

On the back, side, and hind-part of the Foot.

1. *A bursa of the tibialis anticus*, between its tendon, the lower part of the tibia, and capsular ligament of the ankle.

2. *A bursa* between the tendon of the extensor pollicis pedis longus, the tibia and capsular ligament of the ankle.

3. *A bursa of the extensor digitorum communis*, between its tendons, the tibia, and ligament of the ankle.

4. *A large bursa*, common to the tendons of the peronei muscles.

5. *A bursa of the peroneus brevis*, proper to its tendon.

6. *The calcaneal bursa*, between the tendo Achillis and os calcis.

In the Sole of the Foot.

1. *A bursa for the tendon of the peroneus longus.*

2. *A bursa* common to the tendon of the flexor pollicis pedis longus, and the tendon of the flexor digitorum pedis communis longus profundus.

3. *A bursa of the tibialis posticus,* between its tendon, the tibia, and astragalus.

4. *Five bursæ for the flexor tendons,* which begin a little above the first joint of each toe, and extend to the root of the third phalanx, or insertion of the tendons.

Bursa′lis mu′sculus. (From its resemblance to a bursa, or purse.) See *Obturator externus et internus.*

Buseli′num. (From βου, great, and σελινον, parsley.) A large species of parsley.

Bu′ssii spi′ritus bezoa′rdicus. The bezoardic spirit of Bussius, an eminent physician at Dresden. A distillation of ivory, sal-ammoniac, amber, &c.

Butchersbroom. See *Ruscus.*

Bu′tiga. A synonym for gutta rosacea.

Bu′tino. Turpentine.

Bu′tomon. See *Iris pseudacorus.*

BUTTER. (*Butyrum:* from βους, a cow, and τυρος, *coagulum,* or cream.) A concrete and soft substance, of a yellow colour, approaching more or less to that of gold, and of a mild, agreeable taste. It melts by a gentle heat, and becomes solid by cooling. Fresh butter is nourishing and relaxing, but it readily becomes sour, and, in general, agrees with few stomachs. Rancid butter is one of the most unwholesome and indigestible of all foods.

Butter-bur. See *Tussilago petasites.*

Butter-flower. See *Ranunculus.*

Butter-milk. The thin and sour milk which is separated from the cream by churning it into butter.

Butterwort. See *Pinguicula.*

Butua. See *Cissampelos pariera.*

BUTY′RUM. See *Butter.*

Buty′rum antimo′nii. See *Murias antimonii.*

BUXTON WATERS. *Buxtonienses aquæ.* Warm mineral springs, which rise in the village of Buxton, in Derbyshire. They have been long celebrated for their medicinal properties. With respect to sensible properties, the Buxton water cannot be distinguished from common spring water, when heated to the same temperature. Its temperature, in the gentleman's bath, is invariably 82°. The principal peculiarity in the appearance of this spring, is a large quantity of elastic vapour, that rises and forms bubbles, which pass through the water, and break as soon as they reach the surface. The air of these bubbles was ascertained, by Dr. Pearson, to consist of azotic gas, mixed with a small proportion of atmospheric air. Buxton water is frequently employed both internally and externally: one of which methods often proves beneficial, when the other would be injurious: but, as a bath alone, its virtues may not be superior to those of tepid common water. As the temperature of 82° is several degrees below that of the human body, a slight shock of cold is felt on the first immersion into the bath; but this is almost immediately succeeded by a pleasing glow over the whole system. It is therefore proper for very delicate and irritable habits. The cases which derive most benefit from the *external* use of Buxton waters, are those in which a loss of action, and sometimes of sensation, affects particular limbs, in consequence of long-continued or violent inflammation, or external injury. Hence the chronic rheumatism succeeding the acute, and where the inflammation has been seated in particular limbs, is often wonderfully relieved by this bath. The *internal* use of the water has been found to be of considerable service in symptoms of defective digestion, and derangement of the alimentary organs. A judicious use of this simple remedy will often relieve the heartburn, flatulency, and sickness; it will increase the appetite, animate the spirits, and improve the health. At first, however, it sometimes occasions a diarrhœa, which is rather salutary than detrimental; but costiveness is a more usual effect, especially in sluggish habits. It also affords great relief when taken internally, in painful disorders of the bladders and kidneys; and has likewise been recommended in cases of gout; but when taken for these complaints, the addition of some aromatic tincture is recommended. In all cases of active inflammation, the use of these waters should be carefully avoided, on account of their supposed heating properties. A full course consists of two glasses, each containing one-third of a pint, before breakfast; which quantity should be repeated between breakfast and dinner. In chronic cases, a long residence on the spot is requisite to ensure the desired effect.

BU′XUS. (From ϖυκαζω, to become hard.) The box tree.

1. The name of a genus of plants in the Linnæan system. Class, *Monœcia.* Order, *Triandria.*

2. The pharmacopœial name of the *Buxus sempervirens* of Linnæus, the leaves of which possess a very strong, nauseous, bitter taste, and aperient virtues. They are occasionally exhibited, in form of decoction, amongst the lower orders of people, in cases of dropsy and asthma, and worms. As much as will lay upon a shilling, of the common dwarf box, dried and powdered, may be given at bed-time, every night, to an infant.

Bu′xus sempervi′rens. The systematic name of the *buxus* of the pharmacopœias. See *Buxus.*

By′arus. A plexus of blood-vessels in the brain.

Byng. A Chinese name for green tea.

Byre′thrum. (*Beretta*, Ital. or *barette*, Fr. a cap.) *Byrethrus*. An odoriferous cap, filled with cephalic drugs, for the head.

By′rsa. (Βυρσα, leather.) A leather skin, to spread plasters upon.

Bysau′chen. (From βυω, to hide, and αυχην, the neck.) Morbid stiffness of the neck.

By′ssus. (Heb.) A woolly kind of moss. Pudendum muliebre. A kind of fine linen.

By′thos. (Βυθος, deep.) An epithet used by Hippocrates for the bottom of the stomach.

By′zen. (From βυω, to rush together.) In a heap; throngingly. Hippocrates uses this word to express the hurry in which the menses flow in an excessive discharge.

C.

C, In the chemical alphabet, means nitre.

Caa-a′pia. (Indian.) A Brazil root, which, chewed, has nearly the effects of ipecacuanha. It is the *Dorstenia Brasiliensis* of Wildenow. The Brasilians cure the wounds from poisoned darts with the juice of this root, which they pour into the wound.

Caa-atay′a. (Indian.) A bitter plant of Brazil, very powerfully cathartic and emetic. It resembles the euphrasia. *Ray.*

Caaci′ca. (Indian.) A Brazilian herb applied in cataplasms against venomous bites; called also *colubrina Lusitanica. Ray.*

Caa′co. The name of a species of sensitive plant, whose root is used by the natives of America as an antidote to several poisons.

Caaetima′y. *Senecio Brasiliensis.* A decoction of the plant thus called, is used as a wash to cure the itch. Its systematic name is unknown. *Ray.*

Caaghiyu′yo. (Indian.) *Frutex baccifer Brasiliensis.* A shrub of Brazil, whose leaves are applied to ulcers, as desiccative.

Caa-o′pia. (Indian.) *Arbuscula gummifera Brasiliensis. Hypericum bacciferum* of modern naturalists. The name of a tree in the Brasils, whose bark emits a juice, when wounded, which, in a dried state, resembles gamboge, except that it is rather of a darker colour.

Caape′ba. See *Cissampelos pareira.*

Caapo′nga. (Indian.) The Brasilian name for crithmum; also called *Trifolia spica. Crithmum marinum non spinosum. Inula crithmoides* of Linnæus. The leaves and young stalks are pickled for the use of the table, they are gently diuretic.

Caaro′ba. (Indian.) The name of a tree, which grows in the Brasils. A decoction of its leaves promotes perspiration, and is given in the cure of the venereal disease. *Ray.*

Cabali′stica ars. *Cabala. Cabula. Kabala.* The cabalistic art. It is derived from the Hebrew word, signifying to receive by tradition. It is a term that hath been antiently used, in a very mysterious sense, amongst divines; and since, some enthusiastic philosophers and chemists have transplanted it into medicine, importing by it somewhat magical; but such unmeaning terms are now justly rejected.

Cáballine áloes. See *Aloë.*

Cabbage. See *Brassica.*

Cabbage-bark tree. See *Geoffroya Jamaicensis.*

Cabbalistic art. See *Cabalistica ars.*

Caburei′ba. *Caburiiba.* A name of the *Balsamum Peruvianum.* Ray thinks it is the tree which affords that balsam.

Cacago′ga. (From κακκη, excrement, and αγω, to expel.) Cathartics. Ointments which, being rubbed on the fundament, procure stools, according to Paulus Ægineta.

Caca′lia. (From κακον, bad, and λιαν, exceedingly; because it is mischievous to the soil on which it grows.) *Cacamum.* The herb wild chervil, or wild carraways, formerly said to be pectoral.

Cacamotictlano quiloni. (Indian.) *Batatas peregrina.* The purging potatoe.

Ca′camum. See *Cacalia.*

Ca′cao. *Cacoa. Cocoa. Cacavifera. Cacari. Quahoil. Cacavata.* The cocoa or chocolate nut of Virginia and Jamaica.

Cacapho′nia. (From κακος, bad, and φωνη, the voice.) Defective articulation.

Ca′cari. See *Cacao.*

Cacato′ria fe′bris. (From *caco*, to go to stool.) An epithet given by Sylvius to a kind of intermittent fever, attended with copious stools.

Caccio′nde. A sort of pill recommended

by Baglivi against dysenteries; its basis is catechu.

CACHE′XIA. (From *κακος*, bad, and *ἕξις*, a habit.) A bad habit of body, known by a depraved or vitiated state of the solids and fluids.

CACHE′XIÆ. A class of diseases in Cullen's nosology, embracing three orders, viz. *marcores*, *intumescentiæ*, and *impetigines*.

Cache′xia uteri′na. The fluor albus is sometimes so called.

Cache′xia icte′rica. The jaundice, or a disposition thereto.

Ca chlan. The *buphthalmum verum*.

Ca′chlex. A little stone, or pebble. Galen says, that the cachleces, heated in the fire and quenched in whey, become astringents, and useful in dysenteries.

Cachinna′tio. (From *cachinno*, to laugh aloud.) A tendency to immoderate laughter, as in some hysteric and maniacal affections.

Cacho′re. A name for catechu.

Ca′chos. (Indian.) A shrub which the Indians use as a diuretic, and to expel concretions from the kidneys.

CACHU′NDE. A medicine highly celebrated among the Chinese and Indians, made of several aromatic ingredients, perfumes, medicinal earths, and precious stones. They make the whole into a stiff paste, and form out of it several figures, according to their fancy, which are dried for use. These are principally used in the East Indies, but are sometimes brought over to Portugal. In China, the principal persons usually carry a small piece in their mouths, which is a continued cordial, and gives their breath a very sweet smell. It is highly esteemed as a medicine in nervous complaints; and it is reckoned a prolonger of life, and a provocative to venery; the two great intentions of most of the medicines used in the East.

Ca′chrys. Galen says it sometimes means parched barley. In Linnæus's botany, it is the name of a genus of which he enumerates three species.

Ca′chrys odonta′lgica. A plant, the root of which may be substituted for that of the pyrethrum.

Cachy′mia. (Κακυμια.) An imperfect metal, or an immature metalline ore, according to Paracelsus.

Cacoalexite′rium. (From *κακος*, bad, and *αλεξιτηρεω*, to preserve.) An antidote to poison or against infectious diseases. Alexipharmics.

Cacocho′lia. (From *κακος*, and *χολη*, bile.) An indisposition, or disease of the bile.

Cacochy′lia. (From *κακος*, bad, and *χυλη*, the chyle.) Indigestion, or depraved chylification.

CACOCHY′MIA. (From *κακος*, bad, and *χυμος*, juice, or humour.) A diseased or depraved state of the humours.

Cacocne′mus. (From *κακος*, bad, and *κνημη*, the leg.) Having a natural defect in the tibia.

Cacocore′ma. (From *κακος*, bad, and *κορεω*, to purge or cleanse.) A medicine which purges off the vitiated humours.

Cacodæ′mon. (From *κακος*, bad, and *δαιμων*, a spirit.) An evil spirit, or genius, which was supposed to preside over the bodies of men, and afflict them with certain disorders. The night-mare.

Caco′dia. (From *κακος*, bad, and *ωζω*, to smell.) A defect in the sense of smelling.

Cacoe′thes. (From *κακος*, ill, and *ηθος*, a word which, when applied to diseases, signifies a quality, or a disposition.) Hippocrates applied this word to malignant and difficult distempers. Galen, and some others, express by it an incurable ulcer, that is rendered so through the acrimony of the humours flowing to it. Linnæus and Vogel use this term much in the same sense with Galen, and describe the ulcer as superficial, spreading, weeping, and with callous edges.

Cacopa′thia. (From *κακος*, bad, and *ϖαθος*, affection.) An ill affection of the body, or part.

Cacopho′nia. (From *κακος*, bad, and *φωνη*, the voice.) A defect in the organs of speech; a bad pronunciation.

Cacopra′gia. (From *κακος*, bad, and *ϖραττω*, to perform.) Diseased chylopoietic viscera.

Cacorry′thmus. (From *κακος*, bad, and *ρυθμος*, order.) A disordered pulse.

Caco′sis. (From *κακος*, bad.) A bad disposition of body.

Cacosi′tia. (From *κακος*, and *σιτιον*, food.) An aversion to food, or nausea.

Cacosphy′xia. (From *κακος*, bad, and *σφυξις*, pulse.) A disorder of the pulse.

Ca′costo′machus. (From *κακος*, bad, and *ϛομαχος*, the stomach.) A bad or disordered stomach; also food which the stomach rejects.

Caco′stomus. (From *κακος*, bad, and *ϛομα*, a mouth.) Having a bad formed, or disordered mouth.

Cacothy′mia. (From *κακος*, ill, and *ϑυμος*, the mind.) Any vicious disposition of the mind; or a diseased mind.

Cacotro′phia. (From *κακος*, ill, and *τροφη*, nutriment.) A vitiated nourishment; a wasting of the body, through a defect of nutrition.

CA′CTUS. The name of a genus of plants in the Linnæan system. Class, *Icosandria*. Order, *Monogynia*. The melon-thistle.

Ca′ctus opu′ntia. The systematic name of the plant bearing the epithet opuntia in the pharmacopœias. The prickly leaves of this plant abound with a mucilaginous matter, which is esteemed in its native countries an emollient, in the form of poultice.

Cacu′balus. (From *κακος*, evil, and *βαλλω*, to cast out; so named because it was thought to be efficacious in expelling poisons.) The berry-bearing chickweed.

Ca′cule. The Arabian term for cardamoms.

CACU′MEN. (*-minis*, neut.) The top or point.

CADA′VER. (*-veris*, neut. From *cado*, to fall; because the body, when deprived of life, falls to the ground.) A carcase. A body deprived of life.

Ca′dmia. (Heb.) *Chlimia. Catimia.* A name given to the lapis calaminaris. See *Zinc.*

Ca′dmia meta′llica. A name given, by the Germans, to cobalt.

CADOGAN, William, graduated at Oxford in 1755. Five years before, he had published a small treatise on the management of children, which was very much approved. In 1764 his "Dissertation on the Gout and all Chronic Diseases" appeared, which attracted considerable attention, being written in a popular style. He referred the gout principally to indolence, vexation, and intemperance; and his plan of treatment is generally judicious. He was a fellow of the London College of Physicians, and died in 1797, at an advanced age.

Cadu′ca. (From *cado*, to fall down.) See *Decidua.*

Cadu′cus mo′rbus. (From *cado*, to fall down.) The epilepsy or falling sickness.

Cæ′citas. (From *cæcus*, blind.) Blindness. See *Caligo*, and *Amaurosis.*

CÆ′CUM. (From *cæcus*, blind.) The cæcum, or blind gut; so called from its being perforated at one end only. The first portion of the large intestines, placed in the right iliac region, about four fingers' breadth in length. It is in this intestine that the ileum terminates by a valve, called the valve of the cæcum. The *appendicula cæci vermiformis* is also attached to it. See *Intestines.*

CÆ′LIUS Aurelia′nus, is supposed to have been born at Sicca, in Africa, and is referred by Le Clerc to the fifteenth century, from the harshness of his style. He has left a Latin translation of the writings of Soranus, with additional observations, partly collected from others, partly from his own experience. The work is in eight books, three on acute, the rest on chronic disorders. He treats of several diseases not mentioned by any earlier writers, and has some observations in surgery peculiar to himself; he appears too generally judicious in his remarks on the opinions of others.

Cæ′ros. (*Καιρος.*) Hippocrates, by this word, means the opportunity or moment in which whatever is to be effected should be done.

CÆSALPI′NUS, Andrew, was born in Tuscany in 1519. He graduated at Pisa, and become professor in anatomy and medicine there; and was afterwards made physician to Pope Clement VIII. He died in 1603. His works are numerous, and evince much genius and learning. In 1571 he published a work, defending the philosophy of Aristotle against the doctrines of Galen, from some passages in which he appears to have approached very near to a knowledge of the circulation of the blood; having explained the use of the valves of the heart, and pointed out the course which these compelled the blood to take on both sides during the contraction and dilatation of that organ. In a treatise "De Plantis," he justly compared the seeds to the eggs of animals; and formed an arrangement of them according to the parts of fructification. On medical subjects also he offered many judicious remarks.

CÆSA′RIAN OPERA′TION, (So called because Julius Cæsar is said to have been extracted in this manner.) *Hysterotomia. Hysterotomatocia.* The operation for extracting the fœtus from the uterus, by dividing the integuments of the abdomen and the uterus.

There are three cases in which this operation may be necessary. — 1. When the fœtus is perceived to be alive, and the mother dies, either in labour or in the last two months. 2. When the fœtus is dead, but cannot be delivered in the usual way, from the deformity of the mother, or the disproportionate size of the child. 3. When both the mother and the child are living, but delivery cannot take place, from the same causes as in the second instance. Both the mother and the child, if accounts can be credited, have often lived after the Cæsarian operation, and the mother even borne children afterwards. Heister gives a relation of such success, in his Institutes of Surgery; and there are some others. In England, the Cæsarian operation has almost always failed. Mr. James Barlow, of Chorley, Lancashire, succeeded, however, in taking a fœtus out of the uterus by this bold proceeding, and the mother was perfectly restored to health.

Cæ′sares. *Cæsones.* Children who are brought into the world by the Cæsarian operation.

Cæ′tchu. See *Acacia catechu.*

Caf. (Arab.) *Cafa. Caffa.* A name given by the Arabians to camphire.

Caga′strum. A barbarous term used by Paracelsus, to express the morbific matter which generates diseases.

Ca′jan. *Cayan.* The *Phaseolus creticus* of Linnæus. A decoction of the leaves restrains the hæmorrhoids when excessive. *Ray.*

Ca′jeput oil. See *Melaleuca.*

CAIUS, John, was born at Norwich in 1510. After studying at Cambridge, and in different parts of Italy, and distinguishing himself by his interpretations of Hippocrates, Galen, and other ancient authors, he graduated at Bologna. In 1544, he returned to this country, and for some time read lectures in anatomy to the corporation of surgeons in London. He afterwards practised at Shrewsbury, having been admitted a fellow of the College of Physicians; and published a popular account of the memorable sweating sickness, which prevailed in 1551, subsequently reprinted, much improved, in Latin. He was made physician to Edward VI., to Mary and to Elizabeth. On the death of Linacre, he was chosen President of the College of Physicians, and during the seven years, for which he held that office, performed many important services. He was also a signal benefactor to Gonvil Hall, where he studied at Cambridge, having obtained permission to erect it into a college, considerably enlarging the building, and assigning provision for three fellows and twenty scholars. He was chosen master on the completion of the improvements, and retained that office till near the period of his death, which happened in 1573. He published a dissertation "De Canibus Britannicis," which Mr. Pennant has entirely followed in his British Zoology, and some other learned works besides those already mentioned.

Cala′ba. The Indian mastich tree. *Catophyllum inophyllum* of Linnæus, a native of America, accounted vulnerary, resolvent, and anodyne.

Calagua′læ radix. *Calaguelæ radix.* The root so called is knotty, and somewhat like that of the polypody tribe. It has been exhibited internally at Rome, with success, in dropsy; and it is said to be efficacious in pleurisy, contusions, abscesses, &c. It was first used in America, where it is obtained; and Italian physicians have since written concerning it, in terms of approbation.

Calamagro′stis. (From *καλαμος*, a reed, and *αγρωϛις*, a sort of grass.) Sheer grass. Reed grass.

Cala′mbac. (Indian.) The agallochum, or aromatic aloe.

Calama′corus. Indian reed.

Calame′don. (From *καλαμος*, a reed.) A sort of fracture which runs along the bone, in a straight line, like a reed, but is lunated in the extremity.

CA′LAMINA PRÆPARA′TA. Prepared calamine. Burn the calamine, and reduce it to powder; then let it be brought into the state of a very fine powder, in the same manner that chalk is directed to be prepared. See *Calamine.*

CA′LAMINE. (From *calamus*, a reed; so called from its reed-like appearance.) *Cadmia. Cathmia. Cadmia lapidosa ærosa. Cadmia fossilis. Calamina. Lapis calaminaris.* An ore of zinc. A sort of stone, or mineral, containing oxide of zinc and carbonic acid, united with a portion of iron, and sometimes other substances. It is very heavy, moderately hard and brittle, of a gray, yellowish, red, or blackish brown; found in quarries of considerable extent, in several parts of Europe, and particularly in this country, in Derbyshire, Gloucestershire, Nottinghamshire, and Somersetshire; as also in Wales. The calamine of England is, by the best judges, allowed to be superior in quality to that of most other countries. It seldom lies very deep, being chiefly found in clayey grounds, near the surface. In some places it is mixed with lead ores. This mineral is an article in the materia medica; but, before it comes to the shops, it is usually roasted, or calcined, to separate some arsenical or sulphureous particles which, in its crude state, it is supposed to contain, and in order to render it more easily reducible into a fine powder. In this state, it is employed in collyria, for weak eyes, for promoting the cicatrization of ulcers, and healing excoriations of the skin. It is the basis of an officinal cerate, called Ceratum calaminæ, by the London College, formerly called ceratum lapidis calaminaris, ceratum epuloticum; and ceratum carbonatis zinci impuri by the Edinburgh College. These compositions form the cerate which Turner strongly recommends for healing ulcerations and excoriations, and which have been popularly distinguished by his name. The collyria in which the prepared calamine has been employed, have consisted simply of that substance added to rose-water, or elder-flower water.

Calamint, common. See *Melissa calamintha.*

Calamint, mountain. See *Melissa grandiflora.*

CALAMI′NTHA. (From *καλος*, beautiful, or *καλαμος*, a reed, and *μινθη*, mint.) Common calamint. See *Melissa.*

Calami′ntha a′nglica. See *Melissa nepeta.*

Calami′ntha humi′lior. The ground-ivy.

Calami′ntha ma′gno flo′re. See *Melissa grandiflora.*

Calami′ntha monta′na. See *Melissa Calamintha.*

CA′LAMUS. A word of Arabian derivation.

1. A general name denoting the stalk of any plant.

2. The name of a genus of plants in the Linnæan system. Class, *Hexandria.* Order, *Monogynia.*

CA′LAMUS AROMA′TICUS. (From *kalam*, Arab.) Sweet-flag or acorus. See *Acorus Calamus.*

Ca′lamus aroma′ticus Asia′ticus. The *Acorus calamus* of Linnæus.

Ca′lamus odora′tus. See *Acorus calamus.*

Ca′lamus rota′ng. The systematic name of the plant from which we obtain the

Dragon's blood. *Cinnabaris græcorum. Draconthæma. Asagen. Asegen.* Dragon's blood. The red resinous juice which is obtained by wounding the bark of the *Calamus rotang; — caudice densissime aculeato, aculeis erectis, spadice erecto.* It is chiefly obtained from the Molucca islands, Java, and other parts of the East Indies. It is generally much adulterated, and varied in goodness and purity. The best kind is of a dark red colour, which, when powdered, changes to crimson: it readily melts and catches flame, has no smell, but to the taste discovers some degree of warmth and pungency. The antient Greeks were well acquainted with the adstringent power of this drug; in which character it has since been much employed in hemorrhages, and in alvine fluxes. At present, however, it is not used internally, being superseded by more certain and effectual remedies of this numerous class.

CA'LAMUS SCRIPTO'RIUS. A kind of canal at the bottom of the fourth ventricle of the brain, so called from its resemblance to a writing pen.

Ca'lamus vulga'ris. See *Acorus Calamus.*

Calathiana. (From καλαθος, a twig basket; so called from the shape of its flowers.) The herb marsh-gentian, or *Gentiana pneumonanthe* of Linnæus.

Calbia'num. The name of a plaster in Myrepsus.

Calca'dinum. Vitriol.

Calca'dis. An Arabian name for white vitriol and alkali.

CALCA'NEUM. (From *calx*, the heel.) *Calcar pterna. Os calcis.* The largest bone of the tarsus, which forms the heel. It is situated posteriorly under the astragalus, is very regular, and divided into a body and processes. It has a large *tuberosity* or knob, projecting behind to form the heel. A *sinuous cavity*, at its fore part, which, in the fresh subject, is filled with fat, and gives origin to several ligaments. Two *prominences*, at the inner and fore part of the bone, with a pit between them, for the articulation of the under and fore part of the astragalus. A *depression*, in the external surface of the bone near its fore-part, where the tendon of the peronæus longus runs. A large *cavity*, at the inner side of the bone, for lodging the long flexors of the toes, together with the vessels and nerves of the sole. There are two *prominences*, at the under and back part of this bone, that give origin to the aponeurosis, and several muscles of the sole. The anterior surface of the os calcis is concave, for its articulation with the os cuboides, and it is articulated to the astragalus by ligaments.

Calca'nthum. (From χαλκος, brass, and ανθος, a flower; i. e. flowers of brass.) *Calcanthos.* Copperas. Vitriol.

Ca'lcar. (From *calx*, the heel; also from *caleo*, to heat.) The heel-bone; also the furnace of a laboratory.

Calcáreous earth. See *Calx and Lime.*

Calca'ris flos. The larkspur.

Calca'rius la'pis. Limestone.

Ca'lcatar. A name for vitriol.

Ca'lcaton. White arsenic. Troches of arsenic.

Calcatri'ppa. See *Ajuga pyramidalis.*

Calce'na. *Calcenonius. Calcetus.* Paracelsus uses these words to express the tartarous matter in the blood; or that the blood is impregnated with tartarous principles.

Ca'lces, meta'llic. Metals which have undergone the process of calcination, or combustion; or any other equivalent operation.

Ca'lceum equi'num. (From *calceus*, a shoe, and *equus*, a horse; so called from the figure of its leaf.) The herb tussilago, or colt's foot.

Calchi'theos. (From καλχιον, purple.) Verdigrise.

Calchoi'des. (From χαλιξ, a chalkstone, and ειδος, form.) *Calchoidea ossicula.* A name of the cuneiform bones.

Calcidi'cium. The name of a medicine in which arsenic is an ingredient.

Calci'fraga. (From *calx*, a stone, and *frango*, to break; so named from its supposed property of breaking the human calculus.) Breakstone. The herb spleenwort, or scolopendrium, in *Scribonius Largus.*

CALCINA'TION. Oxidation. The fixed residues of such matters as have undergone combustion are called cinders, in common language, and calces, but now more commonly oxides, by chemists; and the operation, when considered with regard to these residues, is termed calcination. In this general way, it has likewise been applied to bodies not really combustible, but only deprived of some of their principles by heat. Thus we hear of the calcination of chalk, to convert it into lime by driving off its carbonic acid and water; of gypsum, or plaster stone, of alum, of borax, and other saline bodies, by which they are deprived of their water of crytallization; of bones which lose their volatile parts by this treatment, and of various other bodies.

Calcina'tum. *Cinificatum.* Terms applicable to calcined substances.

Calcina'tum ma'jus. It is whatsoever is dulcified by the chemical art, which was not so by nature; such as dulcified mercury, lead, and the like substances, which are very speedily consolidated.

Calcina'tum ma'jus Pote'rii. Mercury dissolved in aqua fortis, and precipitated with salt water. Poterius used it in the cure of ulcers.

Calcina'tum mi'nus. Any thing which is sweet by nature, and speedily cures, as sugar, manna, tamarinds, &c.

Calcino'nia. See *Calcena.*

Ca'lcis a'qua. See *Calx.*

Ca'lcis vi'vi flo'res. The pellicle on lime-water.

Ca'lcis os. See *Calcaneum.*

Calcita'ri. Alkaline salt.

Calcite'a. Vitriol.

Calciteo'sa. Litharge.

Ca'lcithos. Verdigrise.

Calcitra'pa. See *Centaurea calcitrapa.*

Calcitra'pa officina'lis. See *Centaurea solstitialis.*

Calcitre'a. Vitriol.

Calcoi'dea ossi'cula. The cuneiform bones.

Ca'lcotar. Vitriol.

Calculi'fragus. (From *calculus,* a stone, and *frango,* to break.) Having the power to break calculi, or stones in the human body.

1. A synonym of lithontriptic. See *Lithontriptics.*

2. A name sometimes applied to scolopendrium, or the pimpernel, from its supposed virtue.

CA'LCULUS. (Diminutive of *calx,* a lime-stone.) *Calculus humanus. Bezoar microcosmicum.* Gravel. Stone. In English we understand by *gravel,* small sand-like concretions, or stones, which pass from the kidneys through the ureters in a few days; and by *stone,* a calculous concretion in the kidneys, or bladder, of too large a size to pass, without great difficulty. Similar concretions are found occasionally in other cavities, or passages. When a disposition to form minute calculi or gravel exists, we often find nephritic paroxysms, as they are called (see *Nephritis,*) which consist of pain in the back, shooting down through the pelvis to the thighs; sometimes a numbness in one leg, and a retraction of either testicle in men, symptoms arising from the irritation of a stone passing through the ureters, as these cross the spermatic cord, on the nerves passing to the lower extremities. These pains, often violent, are terminated by the painful discharge of small stones through the urethra, and the patient is for a time easy. What, however, is meant by the stone is a more serious and violent disease. It is singular that these discharges of small gravel do not usually terminate in stone. Many have experienced them during a long life, without any more serious inconvenience: while the latter is a disease chiefly of the young, and depending on circumstances not easily explained. If the stone attacks persons more advanced in age, it is often the consequence of paroxysms of gout, long protracted, and terminating imperfectly.

When once a stone has acquired a moderate size, it usually occasions the following symptoms: — frequent inclination to make water, excessive pain in voiding it drop by drop, and sometimes a sudden stoppage of it, if discharged in a stream; after making water, great torture in the glans penis, which lasts one, two, or three minutes; and, in most constitutions, the violent straining makes the rectum contract and expel its excrements; or, if it be empty, occasions a tenesmus, which is sometimes accompanied with a prolapsus ani. The urine is often tinctured with blood, from a rupture of the vessels, and sometimes pure blood itself is discharged. Sometimes the urine is very clear, but frequently there are great quantities of slimy sediment deposited at the bottom of it, which is only a preternatural separation of the mucilage of the bladder, but has often been mistaken for pus. The stone is a disease to which both sexes and all ages are liable; and calculi have even been found in the bladders of very young children, nay of infants only six months old.

Women seem less subject to this complaint than men, either owing to constitutional causes, or to the capaciousness, shortness, and straightness of their urethræ, allowing the calculi to be discharged while small, together with the urine.

Chemical analysis of Urinary Calculi.

It is only since the time of Scheele that we have become acquainted with the nature of urinary calculi, this subject having been quite in the dark before that great chemist discovered, in the year 1776, a peculiar acid (the lithic acid) in them, and at the same time found them usually to contain no lime, a circumstance which was soon after confirmed by the experiments of Bergman. From this period, the chemists bestowed a particular attention upon the examination of urinary concretions, as appears from the writings of Dobson, Percival, Falconer, Achard, Hartenkeit, Tychsen, Link, Titius, Walther, Gartner, Brugnatelli, Pearson, and several others, some of whom confirmed the discovery of Scheele, while others contracted, and others enlarged it.

But we are particularly indebted to Fourcroy and Vauquelin, who, since 1786, had turned their attention on this subject, for having made many experiments, by which great light is thrown on the nature of urinary concrements. The following are the interesting results of their chemical inquiries.

The Seat and Physical Properties of Urinary Calculi.

Calculi are found in different parts of the urinary system, in the pelvis of the kidney, in the ureters, in the bladder and urethra; but as they, for the most part, originate in the kidney, the calculi renales make the nucleus of the greatest number of urinary stones. The *calculi renales* differ greatly with respect to their external qualities; for the most part, however, they consist of small, concrete, roundish, smooth, glossy, and crystalline bodies, of a red-yellow colour, like that of wood, and so hard as to admit of polishing. On account of their minuteness, they easily pass through the urinary passages in form of gravel, which being sometimes of a rough surface, cause several complaints on their passage. But in some instances they are of too great a size to be able to pass along the ureters; in which case they increase in the kidneys, sometimes to a great size. Calculi renales of this kind are generally of a brown, dark red, or black colour, and surrounded with several strata of coagulated blood and pus; they have also been observed of a yellow, reddish, and lighter colour; and some consisting of an homogeneous stony mass, but white or grey calculi renales are very rarely to be met with. Amongst the great number that were examined, one or two only were found of a grey or blackish colour, and of a composition similar to those which generally bear the name of mulberry-like stones.

The stones in the ureters, which, on passing into the ureters, are prevented by their size from descending into the bladder, frequently increase very much: they, however, rarely occur; their colour is white, and they consist of phosphate of lime.

The stones in the bladder are the most frequent urinary concrements that have been principally examined; they draw their first origin from the kidneys, whence they descend into the bladder, where they increase; or they immediately originate and increase in the bladder; or they arise from a foreign body that by chance has got into the bladder, which not unfrequently happens, particularly in the female sex. Concretions of this kind differ greatly in their respective physical qualities and external form, which, however, is generally spherical, oval, or compressed on both sides; and sometimes, when there are several stones in the bladder, they have a polyhedrous or cubical form; their extremities are frequently pointed or roundish, but they are very seldom found cylindrical, and more rarely with cylindrical ends.

There is a great variety in the size of the calculi, and likewise in their colour, which is materially different, according to their respective nature and composition. They occur, 1. of a yellowish colour, approaching nearly to red, or brown; such stones consist of lithic acid. 2. Grey, or more or less white; these stones always contain phosphates of earths. 3. Dark grey, or blackish; stones of this colour have oxalates of earths. Many stones shew brown or grey spots, on a yellow or white ground, generally raised on the surface, and consisting of oxalate of lime, which is enclosed in lithic acid, when the ground-colour of the stone is of a wood colour, or in phosphate of lime, when it is white. These spots are, in general, only to be observed in the middle of the stone, or at one of its extremities.

All that is here stated, is the result of observations on more than 600 calculi; and different other colours, that are said to have been observed, either arise from heterogeneous substances, or are merely variations of the above colours. Their surface is smooth and polished in some, in others only smooth, and in others uneven, and covered with rough or smooth corpuscles, which are always of a yellow colour; in some, the surface is partly smooth and partly rough. The white ones are frequently even and smooth, half transparent, and covered with shining crystals, that generally indicate phosphate of ammonia, with magnesia, or they are faint, and consist of minute grains; or rough, in which case they consist of phosphate of lime. The brown and dark grey stones are, from their similarity to mulberries, called mulberry-stones, and being frequently very rugged, they cause the most pain of all.

On examining the specific weight of urinary calculi in more than 500 specimens, it was found to be, in the lightest, as 1213.1000, in the heaviest, as 1976.1000. Their smell is partly strong, like urine or ammonia, partly insipid, and terreous; especially the white ones, which are like sawed ivory, or rasped bone.

The internal texture of calculi is but seldom guessed from their external appearance, particularly when they exceed the size of a pigeon's egg. On breaking them, they generally separate into two or there strata, more or less thick and even, which prove that they are formed by different precipitations, at different times. In the middle, a nucleus is generally seen, of the same mass as the rest. When the place they are broken at is finely streaked, and of a yellow or reddish colour, the lithic acid predominates; but when they are half transparent, luminous like spar, they have ammoniacal phosphate of magnesia in them, and phosphate of lime, and then they are brittle and friable; but when they are so hard as to resist the instrument, of a smooth surface, and a smell like ivory, they contain oxalate of lime. It frequently happens, that the exterior stratum consists of white phosphate of earth, while the nucleus is yellow lithic acid, or oxalate of lime, covered sometimes with a yellow stratum of lithic acid, in which case the nucleus appears radiant; but when it consists of lithic acid, and is covered with white phosphate of earth, it is roundish, oval, and somewhat crooked. These concretions have very seldom three strata; namely, on the outside a phosphate, towards the inside lithic acid, and quite withinside an oxalate of lime; but still rarer these substances occur in more strata, or in another order, as beforementioned.

Stones of the urethra are seldom generated in the urethra itself; however, there are instances of their having been formed in the fossa navicularis, by means of foreign bodies that have got into the urethra. We also very frequently observe stony concrements deposited between the glans and prepuce. All the concretions produced in the inside and outside the urethra consist of phosphate of earths, which are easily precipitated from the urine. There are likewise stones in the urethra which have come out of the bladder, having been produced there, or in the kidneys; and they generally possess the properties of stones of the kidneys.

The different constituent Particles of Urinary Calculi.

It has been mentioned before, that Scheele found a peculiar acid in the urinary concretions, and likewise that phosphate of lime was discovered in them. The identity of the lithic acid, however, was much doubted by modern chemists, particularly by Dr. Pearson, who asserted that it was merely an oxide, whereby he gave rise to the discoveries which Fourcroy and Vauquelin have since made on this subject, because they were induced to repeat the experiments, in order to examine whether the lithic acid were really an acid. Their endeavours were fully rewarded, as they not only found the lithic acid and phosphate of lime in the different calculi, but also five other substances, viz. the lithate of ammonia, oxalate of lime, siliceous earth, phosphate of ammoniacal magnesia, and an animal matter.

1. *Of the Lithic or Uric Acid.*

The acid discovered by Mr. Scheele, in the urinary concretions, was styled lithic acid, or, according to Dr. Pearson's Researches, uric acid; which, after Scheele, has the following properties. It is insipid, without smell, hard, crystallizable, not soluble in cold water, and in boiling water only in several thousand times its quantity. The solution, after having become cool, deposits the acid in form of minute yellow needles, easily soluble in the lye of fixed alkalies, out of which, however, it is precipitated by all acids (even the carbonic acid), except the sulphuric and muriatic, which have no effect on it. Concentrated nitric acid, on dissolving it, obtains a red colour. On distilling the lithic acid, it yields a small quantity of sublimed, undecomposed acid, very little oil and water, crystallized carbonate of ammonia, carbonic acid, and a very black coal, which, however, contains neither alkali nor lime. Besides these properties, it possesses still others. On rubbing it with concentrated lye of potash or soda, it immediately forms a saponaceous, thick, and pulpy mass, which is very soluble in water, when saturated with alkali, but little soluble when only neutralized with it. The neutral combinations have little taste, are not crystallizable, and, when diluted with water, the muriatic acid precipitates the uric acid in form of small, needle-like, shining, somewhat yellowish crystals. Ammonia receives very little of it, which combination is almost indissoluble. Lime-water has likewise very little effect on it, and the carbonates of alkalies none at all. On being dissolved in nitric acid, a part of the lithic acid is changed into oxalic acid. The red colour which appears after this combination, is said by Pearson to prove that substance to be merely an oxide; but it arises from a peculiar animal matter. When oxygenated muriatic acid is brought in contact with lithic acid, the colour of it grows pale, it puffs up, becomes soft and gelatinous, and at last obtains the consistency of a milky liquor; from which process, only one-sixtieth of a white, light, animal substance remains, and a quantity of carbonic acid evolves itself under continual slow effervescence. The liquor yields muriate of ammonia, oxalate of ammonia, both in crystals, free muriatic and malic acid; consequently the oxygenated muriatic acid separates the uric acid into ammonia, carbonic acid, oxalic acid, and malic acid, whereby we observe that the oxygenated muriatic acid changes the uric acid, first into ammonia and malic acid, but on the addition of more acid, into oxalic acid: and when still more acid is added, into water and carbonic acid. The remaining white substance is the same, from which the red colour originates that appears on the combination of the uric acid with nitric acid, and which imparts the cubical form to the muriate of ammonia, obtained by the evaporation of the liquor. It remains now to be stated what is observed in the distillation of that acid, by which it yields, not only carbonate of ammonia, but also carbonic gas, very little oil, Prussic acid, partly in form of gas, partly fluid, a considerable quantity of coal that contains no salt, and a little water. The productions thus obtained have the smell of bitter almonds. The results of these inquiries manifestly shew, that the lithic acid is really a distinct acid from all others, consisting of azote, carbon, hydrogen, and oxygen. This peculiar acid is an excrementitious substance, which is carried off by the urine, and, at the forming of calculi, combines itself with a coloured animal matter, from which also it probably originates by a process still unknown.

2. *Of the Lithate of Ammonia.*

This substance seems to have been unknown before, or at least not properly discerned from the uric acid; and, though Scheele has observed it, he was ignorant of its particular nature. It is easily to be distinguished, by the small even strata in which it is formed, by its colour, that looks like milk coloured with coffee, and by its forming but small calculi. It dissolves in the lees of fixed alkalies like the lithic acid, but with the characteristic difference that it discharges ammonia, a phenomenon already observed by Scheele. It is more soluble in cold as well as warm water, than the lithic acid. It is in the same way affected by acids, except that a greater quantity is required for changing it. It is generally mixed with phosphate of ammoniacal magnesia, because it seems only to be produced after a sufficient quantity of ammoniacal magnesia has been formed, to saturate the phosphoric acid.

3. *Of the Phosphate of Lime.*

The existence of this substance had hitherto been but inaccurately determined, every substance which was not lithic acid being formerly comprised by the name of phosphate of lime. It occurs in small friable strata, which break in scales, or splints, of a grey white colour, and are faint, opaque, without any smell or taste, and crystallized in a luminous or spar-like form; instead of strata, it is frequently composed of friable grains, that slightly cohere, and has many holes and pores, like a spongy texture. It never forms a calculus by itself, being in a calculus always united with an animal gelatinous matter; on account of which circumstance it becomes black by exposing it to strong heat; and burns to coal, exhaling the odour of burned bones; and yields water, oil, carbonate of ammonia, and a carbonaceous residuum. Being calcined white, it only leaves lime, and phosphate of lime, without any water of crystallization. It is not soluble in cold water, but in boiling water a part of its gelatine dissolves, spreading an animal odour. All acids, except the boracic and carbonic acid, dissolve it, leaving on the bottom of the vessels transparent spots of animal matter. These solutions are all precipitated by alkalies, but without any decomposition, the precipitate remaining phosphate of lime. On treating the phosphate of lime with concentrated sulphuric acid, a thick pulpy mass of acid-sulphate and phosphate of lime will be obtained, on which pure alkalies, as well as carbonates of alkalies, have no effect. We never could find acid-phosphate of lime, as Brugnatelli pretends to have observed.

4. *Of the Phosphate of Ammoniacal Magnesia.*

It consists of scaly, half-transparent, hard, and coherent strata; can be sawed without crumbling, and reduced to a fine, soft, and white powder. It is of a sweetish insipid taste, somewhat soluble, and crystallized in rhomboids, or thick laminas, dispersed in the cavities of other calculous substances; and it is frequently found on the surface of other calculi. It contains, betwixt its strata, a gelatinous substance, but less than the phosphate of lime, on which account it also blackens by being heated. Though it be but little soluble in water, yet it dissolves in such a quantity as to be capable of crystallizing by slow evaporation. Acids dissolve it more quickly than they do the phosphate of lime. Weak sulphuric acid entirely dissolves it, forming sulphate of ammoniacal magnesia. In diluted muriatic or nitric acid, it disappears more quickly than phosphate of lime. Ammonia, by which that salt is made turbid, only precipitates small particles of magnesia. The lees of fixed alkalies disengage from it ammonia, without forming with it a solution; and, depriving it of the phosphoric acid, leave the magnesia behind.

5. *Of the Oxalate of Lime.*

It is, according to our observations, only found in the mulberry-like calculi, in combination with a coloured animal matter, and consisting of strata covered with pointed, roundish, rough or smooth protuberances; outside it appears of a dark or brown colour, but internally it is grey, frequently with white streaks, of a solid texture, and may be polished like ivory; it breaks in scales, or in the shape of shells; and, on being pounded, or sawed, it exhales an animal odour, like semen. It is the heaviest of all calculous substances, and the only one which yields one-third of lime by calcination. It dissolves with difficulty in acids, and is precipitated unaltered by alkalies from nitric acid. The fixed alkalies decompose it when they are impregnated with carbonic acid, and when it is pulverized, and the solution heated, whereby carbonate of lime and oxalates of alkalies are obtained.

The great quantity of animal matter which constantly adheres to this oxalate of lime is very characteristic, it imparts the brown, reddish, blackish colour to the above kind of stones, and likewise the fine and solid texture. This substance may be obtained by putting small pieces of these stones into diluted nitric acid, whereby it appears of the same colour, and becomes soft and spongy. The great hardness of this kind of calculous substance, most probably arises from the intimate connection of its particles, produced by the combination of the oxalate of lime with animal matter, in the same way as lime obtains a great degree of solidity by its combination with albuminous matter, of which, and of a peculiar matter of urine, that animal substance seems to consist.

6. *Of the Siliceous Earth.*

Amongst 600 calculi that were examined, there were only two which contained this earth; both had the texture of mulberry-like stones, though of a lighter colour, and by being calcined, lost one-third of their weight, without giving free-lime; heated with acids they lost nothing, but when melted with four times as much of alkali, they yielded siliceous earth by being treated with muriatic acid. They contained phosphate of lime, and an animal matter similar to that which is united with the oxalate of lime. They were hard, difficult to be sawed and pulverized, and the powder made scratches in metal. On being burnt, they emitted an animal odour; they imparted nothing to boiling water, and to the acids a little phosphate of lime, which difficultly separates from the siliceous earth. Alkalies, either pure or combined with carbonic acid, did not affect them, merely depriving them of a part of their animal matter. Their essential character consists in their being fusible and vitrifiable with fixed alkalies.

7. *Of the Animal Matter.*

All the six substances just examined, which constitute the urinary calculi of the human species, are always combined with an animal matter, as appears from its being burnt to coal, from the productions it yields by distillation, from its stench on being burnt, and from the cellulous membranous flocculi, which remain when pieces of calculi are dissolved in diluted acids. This animal matter has been frequently, and with good reason, considered as the basis of all urinary concretions, like as in bones the gelatinous matter, the first basis of the bones, forms an organic texture, in the interstices of which the phosphate of lime is deposited. It is very remarkable, that the different constituent particles of urinary calculi are combined with a dissimilar animal matter, which is sometimes albuminous, sometimes gelatinous, sometimes composed of both, and frequently united with the matter of urine. Thus the lithic acid, or the lithate of ammonia, contains a third of albuminous matter, combined with the matter of urine; the phosphates of earths, albuminous matter, gelatine in form of membranes, and laminas, or tela cellulosa; the oxalate of lime, a spongy, yet more solid texture, of the colour of albumen; and the siliceous earth, a similar substance. On the whole, the animal matter seems to unite and join together all the acid and saline particles of urinary concretions.

The Classification of Urinary Stones.

The old classification of urinary calculi, made according to their figure and their size, cannot at present, where we have acquired so accurate a knowledge of their internal nature, be retained, as they ought rather to be classed according to their constituent particles; however no regard is to be had to the animal matter, as being found in all urinary concretions, and having no influence on their respective difference. On comparing the results of the analyses of more than 600 stones, Fourcroy was induced to bring them under three genera; *the first* of which comprehends such stones as are merely composed of one substance, besides the animal matter; *the second*, contains urinary concretions, consisting of two substances, besides the animal matter; and *the third*, comprises all those which are formed by more than three calculous substances. These three genera comprehend about twelve species, namely, the first genus three, the second seven, and the third two; but it must be remembered that the number of the genera, as well as of the species, is determined after the observations hitherto made, and may consequently be increased in future.

1. *The first species* of urinary concretions consists of lithic acid, and stones of this kind most frequently occur, as there were, amongst 600, about 150. They are easily distinguished by their reddish or high yellow colour, much resembling that of wood, by their brittle, radiant-like, homogeneous, and fine texture, and by their perfect solubility in the lyes of fixed alkalies, without disengaging the smell of ammonia. Their size vaires from the bigness of a pea to that of a duck's egg, &c. and their figure is roundish, spheroid, compressed, oval, oblong, &c. the surface polished like marble, but frequently rough and warty; of a crimson light red, yellowish, or light brown colour, but never white, grey, or black; their strata differ in number and thickness, and are frequently of a smooth surface. The specific weight of these stones is from 1.276 to 1.786, but generally more than 1.500. The urinary concretions in the kidneys are mostly of this species.

2. *The second species* is composed of lithate of ammonia, and differs from the former by disengaging ammonia on their being dissolved in the lyes of fixed alkalies. Concretions of this kind are generally small, of a pale or grey colour, and consist of fine strata, easily separable from each other; they mostly contain a nucleus, which is easily separated from the strata that cover it. Their figure is generally oblong, compressed like almonds, and of a smooth surface, which is frequently crystalline. Their specific weight varies from 1.225 to 1.720. They are entirely soluble in water, particularly when previously pulverised. All acids, principally the muriatic acid, deprive them of the ammonia, leaving the pure lithic acid behind. They are frequently found covered with a thin stratum of lithic acid. Amongst 600 calculi there were but few of this kind.

3. *The third species*, consisting of oxalate of lime, are easily to be distinguished by the protuberances and inequality of their surface, whence they have got the appellation of mulberry-like stones; by their hardness, grey colour, solid texture, their polish like ivory, in the inside, and their

particular smell on being sawed, which resembles that of semen. A peculiar characteristic, which distinguishes them from all others, consists in their leaving lime after the calcination, in their being with difficulty soluble in acids and not soluble in alkalies, and, at last, in their being only decomposed by the lees of carbonates of alkali. They weigh from 1.428 to 1.976, and their size varies from that of a calculus renalis to the bigness of an egg, or more; their figure is generally spherical or spheroid. They often make the nucleus of other stones, in which case they belong to another species. In 300 stones they bore the proportion of one-fourth or one-fifth.

4. *Stones of this species* contain lithic acid and phosphate of earth, but in a separate state. Their surface is white, cretaceous, brittle, and half-transparent, as it either consists of phosphate of lime, or of phosphate of ammoniacal magnesia, the kernel being formed by lithic acid; thus both constituents are exactly separate from each other. They were found in the proportion of one-twelfth amongst the stones that were examined, and they grow bigger than any of the rest, as they appear from the size of an egg to that of the whole bladder, even when extended. They generally have an oval form, often pointed at one end, of a smooth surface, which, however, is frequently covered with crystals of phosphate of ammoniacal magnesia. Sometimes the lithic acid in the middle is alternately covered with phosphate of lime, and phosphate of ammoniacal magnesia. The specific weight of these stones is extremely variable.

5. *The fifth species of calculi* contains, likewise, lithic acid and phosphates of earth, but intimately mixed with each other. Of these stones, a great many varieties are observed, depending on the proportionable quantity of their constituent particles, as well as on the strata in which they lie above one another. The chief constituents, the phosphates of earths, are separated in different strata, but sometimes so intimately mixed with each other, that it is impossible to distinguish them with the eye; and the analysis could only shew their difference. From this circumstance arise the variety in the colour, figure, and number of the strata. The colour, however, is generally grey, but frequently variegated like marble, sometimes like soap. Their figure is irregular, oval, or globular, and the surface mostly brittle, cretaceous, or whitish, so as to make us believe that they only consist of phosphate of lime. The polyhedrous stones generally belong to this species, when they have the appearance of being worn away by rubbing. They make about one-fifth of the stones that were examined. Their specific weight varies extremely, the least being 1.213, the greatest 1.739.

6. *This species* is constituted by lithate of ammonia and phosphate of earth, *i. e.* of lime and ammoniacal magnesia; and resembles in its external appearances the fourth species. One of the constituents, generally the lithate of ammonia, makes the nucleus, while a mixture of the two others, but rarely one by itself forms the crust. Sometimes, however, the nucleus contains also the phosphates, and the crust a little lithate of ammonia, which, even in some varieties, is mixed with pure lithic acid. The strata in stones of this kind are more easily separable, and always smaller than those of the fourth species. The specific weight is 1.312 to 1.761; and they are more rarely met with than most of the rest. Amongst 600 there were only twenty of this kind.

7. Stones of the *seventh species* consist likewise of lithate of ammonia and phosphate of earths, but intimately mixed with each other. They are of a paler colour, much lighter than the first species, and disengage a great deal of ammonia on their being treated with potash. We found them only in the proportion of one-fortieth amongst the stones which we have analysed. They never grow so large as the two former.

8. The constituent particles of the *eighth species* are phosphate of lime and phosphate of ammoniacal magnesia. The pure white colour, the friability, their being insoluble in alkalies, and their easy solubility even in weak acids, constitute the chief characteristics of this sort of stones, of which about 60 were found amongst 600: sometimes they are of an enormous size, of irregular form, rarely round, but frequently of an uneven surface, and resembling an incrustation. Their texture is formed of white brittle strata; sometimes interwoven with solid half-transparent crystals of phosphate of ammoniacal magnesia. The crusts formed on foreign bodies that happened to penetrate into the bladder, belong to this species; the specific weight of which is 1.138 to 1.473.

9. This species of calculi contains oxalate of lime, but externally uric acid, in more or less quantity, and are only to be distinguished by the nucleus from the first species. The proportion of both constituents, and the specific weight, vary extremely, the latter being 1.341 to 1.754. Sometimes the nucleus, consisting of oxalate of lime, is only covered on one side with uric acid, and discernible on the other by protuberances with which the surface is variegated; which variety, however, seldom occurs.

10. Stones of this species have, in their centre, oxalate of lime, surrounded by phosphates of earths; the kernel is grey, or brown, and radiant-like, the crust white and cretaceous; their size and figure differ extremely, and their specific weight is from

1.168 to 1.752. They amount to one-fifth of the 600 stones that were examined.

11. This species contains stones composed of three or four calculous substances, namely, of oxalate of lime, phosphates of earths, and uric acid, either pure or combined with ammonia. They rarely occur; and amongst 600 stones only ten or twelve were observed. They often consist of three distinct strata, viz. in the interior, of oxalate of lime; in the middle, of lithate of ammonia; and the exterior of phosphates of earths, which are frequently mixed with uric acid or lithate of ammonia, all which are distinguished on their being sawed through. This species comprehends three varieties; the first of which consists of oxalate of lime, uric acid, and phosphates of earths; the second contains lithate of ammonia, combined with pure uric acid, and the two other constituents; the third has, besides these substances, free uric acid and lithate of ammonia, mixed with the phosphates of earths. We forbear to mention other varieties of this species, as being less remarkable and instructive.

12. The last species of calculi is of a very complicated composition. The siliceous earth seems to have taken the place of the oxalate of lime; it is mixed with uric acid and lithate of ammonia, and covered by phosphates of earths. Stones of this kind are the rarest of all, and there were only *two* amongst 600.

The causes of the Generation of Urinary Calculi.

To inquire into the causes by which urinary concretions are produced, is both interesting and useful, however attended with the greatest difficulties. The writings of medical authors are full of conjectures and hypotheses with regard to this subject, on which nothing could be ascertained before we had acquired an accurate knowledge of the nature of urinary concretions. It is owing to this circumstance that the most enlightened physicians acquiesced in ascribing the immediate cause of them to a superabundance of terreous matter in the urine; and Boerhaave, as well as, particularly, Van Swieten, imagined that the urine of all men contained calculous matter in the natural state, and that, for the generation of stones, a nucleus was only required, to attract it. That this may be the case, in some instances, is proved by frequent experience; but stones produced by foreign bodies, that have accidentally got into the urethra or bladder, are always white and composed of phosphates of earths, and seldom or never covered with lithic acid, a substance which is observed to form the stones that most frequently occur; but even in these the nucleus consists of a substance formed in the body itself, as a particle descended from the kidneys, &c. which must, therefore, have necessarily originated in a peculiar internal cause. A superabundance of uric acid in stony patients, and its more copious generation than in a sound state, though it seems to be one of the principal and most certain causes, is by no means satisfactory, as it only explains the precipitation of stony matter from the urine, but not why it unites in strata. A coagulating substance is required for separating, attracting, and, as it were, agglutinating the condensible particles that are precipitated. This substance is undoubtedly the animal matter which we have constantly found in all calculous masses, and which seems to constitute the basis of stones, like the membranous gelatina that of bones. It is known that the urine of calculous patients is generally muddy, ductile, in threads, slimy, and as if mixed with albumen, which quality it obtains at the moment when the ammonia is disengaged, or on the addition of potash that separates it from the acid in which it was dissolved; and in all cases of superabundance of lithic acid the urine contains a great quantity of that animal matter, which promotes the precipitation of it, and attracts, and unites the particles thus separated. Hence it appears, that every thing capable of increasing the quantity of that pituitous gluten in the urine, may be considered as the remote cause of the formation of calculi. And the old ideas on pituitous temperaments, or superabundant pituita, &c. which were thought to dispose people to a calculus, seem to be connected with the late discoveries on the nature of urinary stones. Though the animal matter appears to be different in different calculi, yet it is certain, that every calculous substance contains an animal gluten, from which its concrete and solid state arises; whence we may fairly state the superabundance of that substance as the chief and principal cause of the formation of calculi.

There are, however, other causes which seem to have a particular influence on the nature of urinary stones, and the strata in which they are formed; but it is extremely difficult to penetrate and to explain them. We are, for instance, entirely ignorant of the manner in which urinary stones are formed from the oxalate of lime; though, from their occurring more frequently in children than in adults, we might be entitled to ascribe them to a disposition to acor, a cause considered by Boerhaave as the general source of a great number of diseases incident to the infantile age. This opinion seems to be proved by the ideas of Bonhomme, physician at Avignon, on the oxalic or saccharic acid, as the cause of mollities ossium in the rickets; by this acid being discovered in a species of saliva by Brugnatelli; and, lastly, by an observation of Turgais, who found this acid in the urine of a child diseased with worms. We but rarely observe saccharic acid in the human body, which appears to be mostly adventitious, and by which the animal matter is rendered coagulable, and deposited, or precipitated, with the oxalate of lime; or the oxalic acid decomposes the phosphate of lime, and forms an insoluble combination, incapable of being any longer kept dissolved in the urine. It is, however, extremely difficult to determine how far the constitution of the body is connected with that particular disposition in the urine, of precipitating sometimes phosphate of lime mixed with oxalate of lime, sometimes phosphate of ammoniacal magnesia, either by itself or mixed with lithic acid, &c. &c. Who can explain the reason why, of 600 stones, there were only two in which siliceous earth could be traced? Still more difficult is it to explain the causes why the above substances precipitate either at once or in different strata; but it may suffice to have shewn how many observations and experiments are required, and what accurate attention and perseverance are necessary, in order to throw light on so difficult a subject.

The means to be employed in calculous complaints must vary according to circumstances. Permanent relief can be obtained only by the removal of the morbid concretion; and where this is of too large a size to be passed by the natural outlet, the operation of lithotomy becomes necessary. Various remedies indeed have been proposed as capable of dissolving urinary calculi; and some of them are certainly useful in palliating the symptoms, and perhaps preventing the formation of fresh calculous matter: but experience has not sanctioned their efficacy as actual lithontriptics; and by delaying the operation, we not only incur the risk of organic disease being produced, but the concretion may also become friable externally, so as to be with more difficulty removed. Sometimes however the advanced age of the patient, the complication with organic disease, or the exhausted state of the system, may render an operation inexpedient; or he may not be willing to submit to it; we shall then find some advantage from the use of chemical remedies, according to the morbid quality of the urine; that is generally from alkaline or earthy preparations, where a red deposit appears, and from acids where there is a white sediment. Tonic medicines may also be useful, and some of the mild astringents, especially uva ursi, and occasional narcotics, where violent pain attends: sometimes an inflammatory tendency may require fomentations, the local abstraction of blood, and other antiphlogistic measures. The most likely plan of effecting a solution of the calculus must certainly be that proposed by Fourcroy, namely, injecting suitable liquids into the bladder. The most common calculi, containing uric acid, are readily soluble in a solution of potash, or soda, weak enough to be held in the mouth, or even swallowed without inconvenience; those which consist of phosphoric acid neutralized by lime, or other base, the next in frequency, dissolve in nitric or muriatic acid of no greater strength; the most rare variety, made up mostly of oxalate of lime, may be dissolved, but very slowly, in nitric acid, or solutions of the fixed alkaline carbonates, weak enough not to irritate the bladder. However it is not easy to ascertain which of these solvents is proper in a particular case, for most calculi are not uniform throughout, owing probably to the urine having varied during their formation, so that the examination of this secretion will not certainly indicate the injection required. The plan recommended therefore is, the bladder having been evacuated, and washed out with tepid water, to inject first the alkaline solution heated to the temperature of the body, and direct it to be retained for half an hour, or longer, if the person can bear it; then to the liquor voided and filtered add a little muriatic acid, which will cause a white precipitate, if there be any uric acid dissolved; and so long as this happens, the same injection should be used, otherwise diluted muriatic acid is to be thrown in, and ammonia added to it when discharged; whereby phosphate of lime, if there be any, is precipitated: and when neither of these succeeds, diluted nitric acid is to be tried; in each case varying the injection from time to time, as that previously used loses its efficacy. However there appears one source of error in this method, namely, that the urine secreted, while the liquid is retained, may give rise to a precipitate, though none of the calculus may have been dissolved; it would therefore be proper to examine the urine previously, as well as occasionally during the use of injections, and, if necessary, correct its quality by the exhibition of proper internal medicines. See *Lithontriptics* and *Lithotomy*.

Ca'lculus bilia'ris. See *Gall-stones.*

Calda'rium. (From *caleo*, to make hot.) A vessel in the baths of the antients, to hold hot water.

Calefa'cients. (*Calefacientia*, sc. *medicamenta;* from *calidus*, warm, and *facio*, to make.) Medicines, or other substances, which excite a degree of warmth in the parts to which they are applied: as *piper, spiritus vini*, &c. They belong to the class of stimulants.

CALE'NDULA. (*Quod singulis calendis*, i. e. *mensibus, florescat;* so called because it flowers every month.) Marigold.

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia necessaria.*

2. The pharmacopœial name of the Single marigold. Garden marigold. *Calendula sativa. Chrysanthemum. Sponsa solis. Caltha vulgaris.* The flowers and leaves of this plant, *Calendula officinalis; seminibus*

cymbiformibus, muricatis, incurvatis omnibus, of Linnæus, have been exhibited medicinally: the former, as aperients in uterine obstructions and icteric disorders, and as diaphoretics in exanthematous fevers; the latter, as gentle aperients, and to promote the secretions in general.

Calen′dula alpi′na. The *Arnica montana* of Linnæus. See *Arnica.*

Cale′ndula arve′nsis. The wild marigold. See *Caltha.*

Cale′ndula officina′lis. The systematic name of the single marigold plant. See *Calendula.*

Cale′ndula palu′stris. Common single marsh-marigold. See *Caltha palustris.*

Ca′lenture. A febrile delirium, said to be peculiar to sailors, wherein they imagine the sea to be green fields, and will throw themselves into it if not restrained. Bonetus gives an account of it; also Dr. Oliver and Dr. Stubbs. It is probably a species of phrenitis.

Cale′sium. (Indian.) A tree which grows in Malabar, whose bark, made into an ointment with butter, cures convulsions from wounds, and heals ulcers. The juice of the bark cures the aphthæ, and, taken inwardly, the dysentery. *Ray.*

Ca′li. (Arab.) The same as kali.

Calicha′pa. The spina alba, or white-thorn.

Ca′lidum. In medical language, it is commonly used with the adjective *animale,* or *innatum,* for animal heat, or the vis vitæ.

Calie′ta. (From *καλιης*, a nest, which it somewhat resembles.) *Calliette.* A fungus growing on the juniper-tree.

CALI′GO. (*Caligo,-ginis,* fœm.) A disease of the eye, known by diminished or destroyed sight; and by the interposition of a dark body between the object and the retina. It is arranged by Cullen in the class *locales,* and order *dysæsthesiæ.* The species of caligo are distinguished according to the situation of the interposed body: thus *caligo lentis, caligo corneæ, caligo pupillæ, caligo humorum,* and *caligo palpebrarum.*

Cali′go le′ntis. *Glaucoma Woulhousi.* The true cataract. See *Cataract.*

Cali′go co′rneæ. An opacity of the cornea. See *Caligo.*

Cali′go pupi′llæ. *Synchysis. Amyosis.* Blindness from obstruction in the pupil. See *Caligo.*

Cali′go humo′rum. *Glaucoma Vogelii.* Blindness from a fault in the humours of the eye. See *Caligo.*

Cali′go palpebra′rum. Blindness from a disorder in the eyelids. See *Caligo.*

Caliha′cha. The cassia-lignea, or cassia-tree of Malabar.

Cali′mia. The lapis calaminaris.

CA′LIX. (*Calix, -icis,* m.; from *καλυπτω*, to cover.) *Calyx.*

1. The term calix is given to the membrane which covers the papillæ in the pelvis of the human kidney.

2. The name of the case, or sheath, in which the flower of plants is concealed before it expands.

Callæ′um. (From *καλλυνω*, to adorn.) *Callæon.* The gills of a cock, which, Galen says, is food not to be praised or condemned.

Calle′na. A kind of salt-petre.

Ca′lli. Nodes in the gout. *Galen.*

Ca′llia. (From *καλος*, beautiful.) A name of the chamomile.

Callible′phara. (From *καλος*, good, and *βλεφαρον*, the eyelid.) Medicines, or compositions, appropriated to the eye-lids.

CALLICO′CCA. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

Callico′cca ipecacua′nha. The plant from which ipecacuan root is obtained was long unknown; it was said by some writers to be the *Psychotria emetica;* class, *Pentandria;* order, *Monogynia:* by others, the *Viola ipecacuanha,* a syngenesious plant of the order Monogynia. It is now ascertained to be neither, but a small plant called *Callicocca ipecacuanha.* There are three sorts of ipecacuan to be met with in our shops, viz. the ash-coloured or grey, the brown, and the white.

The ash-coloured is brought from Peru, and is a small wrinkled root, bent and contorted into a great variety of figures, brought over in short pieces, full of wrinkles, and deep circular fissures, down to a small white woody fibre that runs in the middle of each piece: the cortical part is compact, brittle, looks smooth and resinous upon breaking: it has very little smell; the taste is bitterish and subacrid, covering the tongue, as it were, with a kind of mucilage.

The brown is small, somewhat more wrinkled than the foregoing; of a brown or blackish colour without, and white within: this is brought from Brazil.

The white sort is woody, and has no wrinkles, nor any perceptible bitterness in taste. The first, the ash-coloured or grey ipecacuan, is that usually preferred for medicinal use. The brown has been sometimes observed, even in a small dose, to produce violent effects. The white, though taken in a large one, has scarcely any effect at all. Experience has proved that this medicine is the safest emetic with which we are acquainted, having this peculiar advantage, that, if it does not operate by vomit, it readily passes off by the other emunctories. Ipecacuan was first introduced as an infallible remedy against dysenteries, and other inveterate fluxes, as diarrhœa, menorrhagia, leucorrhœa, &c. and also in disorders proceeding from obstructions of long standing; nor has it lost much of its reputation by time: its utility in these cases is thought to depend upon its restoring perspiration. It has also been successfully employed in spasmodic asthma, catarrhal and consumptive cases. Nevertheless, its chief use is as a vomit, and in small doses, joined with opium, as a diaphoretic. The officinal preparations are the *pulvis ipecacuanhæ compositus*, and the *vinum ipecacuanhæ*.

Calli'creas. (From *καλος*, good, and *κρεας*, meat; so named from its delicacy as food.) The pancreas, or sweet-bread.

Calli'gonum. (From *καλος*, beautiful, and *γονυ*, a knot, or joint; so named from its being handsomely jointed, like a cane.) The polygonum, or knot-grass.

Callioma'rchus. The Gaulish name, in Marcellus Empiricus, for tussilago, or colt's-foot.

Ca'llion. A kind of night-shade.

Calliphy'llum. (From *καλλος*, beauty, and *φυλλον*, a leaf.) The herb adiantum, or maidenhair. See *Adianthum*.

Callistru'thia. (From *καλος*, good, and *ϛρυθος*, a sparrow; because it was said to fatten sparrows.) A fig mentioned by Pliny, of a good taste.

Callitri'cum. (From *καλλος*, beauty, and *ϑριξ*, hair; so named because it has the appearance of long, beautiful hair; or, according to Littleton, because it nourishes the hair, and makes it beautiful.) The herb maidenhair.

Callo'ne. (From *καλος*, fair.) Hippocrates uses this word, to signify that decency and gravity of character and deportment which it is necessary that all medical men should be possessed of.

CALLO'SITAS. Callosity, or preternatural hardness.

CA'LLOUS. A surgical term, signifying hardened or indurated; thus the callous edges of ulcers.

CA'LLUS. (*Callus, i*, m. and *Callum, i*, n.

1. The bony matter deposited between the divided ends of broken bones, about the fourteenth day after the fracture.

2. A preternatural hardness, or induration, of any fleshy parts.

Caloca'tanus. (From *καλος*, beautiful, and *κατανον*, a cup; so called from the beauty of its flower and shape.) The papaver rhœas, or wild poppy.

Calome'lanos turque'ti. So Riverius calls a purgative medicine, composed of calomel and scammony.

Calo'melas. (From *καλος*, good, and *μελας*, black; from its virtues and colour. The preparation called Æthiops mineral, or *hydrargyrus cum sulphure*, was formerly and properly so named. But calomel now means a white preparation of sublimed mercury.) See *Submurias hydrargyri*.

CALO'RIC. (*Caloricum*; from *calor*, heat.) Heat. Igneous fluid.

Heat and cold are perceptions of which we acquire the ideas from the senses; they indicate only a certain state in which we find ourselves, independent of any exterior object. But as these sensations are for the most part produced by bodies around us, we consider them as causes, and judging by appearances, we apply the terms *hot*, or *cold*, to the substances themselves; calling those bodies *hot*, which produce in us the sensation of heat, and those *cold*, which communicate the contrary sensation.

This ambiguity, though of little consequence in the common affairs of human life, has led unavoidably to confusion and perplexity in philosophical discussions. It was to prevent this, that the framers of the new nomenclature adopted the word *caloric*, which denotes that which produces the sensation of heat.

Theories of Heat.

Two opinions have long divided the philosophical world concerning the nature of heat.

1. The one is: that the cause which produces the sensation of heat, is a real, or distinct substance, universally pervading nature, penetrating the particles or pores of all bodies, with more or less facility, and in different quantities.

This substance, if applied to our system in a greater proportion than it already contains, warms it, as we call it, or produces the sensation of heat; and hence it has been called *caloric* or *calorific*.

2. The other theory concerning heat is; that the cause which produces that sensation is *not* a separate or self-existing substance; but that it is merely like gravity, a property of matter; and that it consists in a specific or *peculiar motion, or vibration* of the particles of bodies.

The arguments in favour of the first theory have been principally deduced from the evolution and absorption of heat during chemical combinations; those of the latter are chiefly founded on the production of heat by friction. For it has been observed, that whatever is capable of producing motion in the particles of any mass of matter, excites heat. Count Rumford and Professor Davy have paid uncommon attention to this fact, and proved, that heat continues to be evolved from a body subjected to friction, so long as it is applied, and the texture or form of the body not altered.

All the effects of heat, according to this theory, depend therefore entirely on the vibratory motion of the particles of bodies. According as this is more or less intense, a higher or lower temperature is produced; and as it predominates over, is nearly equal, or inferior to the attraction of cohesion, bodies exist in the gaseous, fluid, or solid state.

Different bodies are susceptible of it in different degrees, and receive and communicate it with different celerity. From the generation, communication, and abstraction of this repulsive motion, under these laws, all the phenomena ascribed to heat are explicable.

Each of these theories has been supported by the most able philosophers, and given occasion to the most important disputes in which chemists have been engaged; which has contributed in a very particular manner to the advancement of the science. The obscurity of the subject, however, is such, that both parties have been able to advance most plausible arguments.

Setting aside all enquiries concerning the merits of these different doctrines, we shall confine ourselves to the general effects, which heat produces on different bodies. For the phenomena which heat presents, and their relation to each other, may be investigated with sufficient precision, though the materiality, or immateriality of it, may remain unknown to us.

Nature of Heat.

Those who consider heat as matter, assert that caloric exists in two states, namely, in combination, or at liberty.

In the first state it is not sensible to our organs, nor indicated by the thermometer; it forms a constituent part of the body; but it may be brought back to the state of sensible heat. In this state it affects animals with the sensation of heat. It therefore has been called sensible or free heat, or fire; and is synonymous with uncombined caloric, thermometrical caloric, caloric of temperature, interposed caloric, &c. expressions now pretty generally superseded.

From the diversity of opinions among chemists respecting the nature of caloric, several other expressions have been introduced, which it is proper to notice. For instance, by *specific heat* is understood, the relative quantities of caloric contained in equal weights of different bodies at the same temperature. *Latent heat* is the expression used to denote that quantity of caloric which a body absorbs when changing its form. It is, however, more properly called *caloric of fluidity*. The disposition, or property, by which different bodies contain certain quantities of caloric, at any temperature, is termed their *capacity for heat*. By the expression of *absolute heat*, is understood the whole quantity of caloric which any body contains.

Methods of exciting and collecting Heat.

Of the different methods of exciting heat, the following are the most usual:

1. *Production of Heat by Percussion or Collision.*

This method of producing heat is the simplest, and therefore it is generally made use of in the common purposes of life for obtaining fire.

When a piece of hardened steel is struck with a flint, some particles of the metal are scraped away from the mass, and so violent is the heat which follows the stroke, that it melts and vitrifies them. If the fragments of steel are caught upon paper, and viewed with a microscope, most of them will be found perfect spherules, and very highly polished. Their sphericity demonstrates that they have been in a fluid state, and the polish upon their surface, shews them to be vitrified.

No heat, however, has been observed to follow the percussion of liquids, nor of the softer kind of bodies which yield to a slight impulse.

2. *Production of Heat by Friction.*

Heat may likewise be excited by mere friction. This practice is still retained in some parts of the world. The natives of New Holland are said to produce fire in this manner, with great facility, and spread it in a wonderful manner. For that purpose, they take two pieces of dry wood; one is a stick, about eight or nine inches long, and the other piece is flat; the stick they bring to an obtuse point at one end, and pressing it upon the other piece, they turn it very nimbly, by holding it between both hands, as we do a chocolate-mill, often shifting their hands up, and then moving down upon it, in order to increase the pressure as much as possible. By this method, they get fire in a few minutes, and from the smallest spark they increase it with great speed and dexterity.

If the irons at the axis of a coach-wheel are applied to each other, without the interposition of some unctuous matter to keep them from immediate contact, they will become so hot when the carriage runs swiftly along, as to set the wood on fire; and the fore-wheels, being smallest, and making most revolutions in a given time, will be most in danger.

The same will happen to mill-work, or to any other machinery.

It is no uncommon practice in this country, for blacksmiths to use a plate of iron as an extemporaneous substitute for a tinder-box; for it may be hammered on an anvil till it becomes red-hot, and will fire a brimstone match. A strong man, who strikes quick, and keeps turning the iron so that both sides may be equally exposed to the force of the hammer, will perform this in less time than would be expected.

If, in the coldest season, one dense iron plate be laid on another, and pressed together by a weight, and then rubbed upon each other by reciprocal motions, they will gradually grow so hot as, in a short time, to emit sparks, and at last become ignited.

It is not necessary that the substances should be very hard; a cord rubbed backwards and forwards swiftly against a post or a tree will take fire.

Count Rumford and Professor Pictet have made some very ingenious and valuable experiments concerning the heat evolved by friction.

3. *Production of Heat by Chemical Action.*

To this belongs the heat produced by combustion. There are, besides this, many chemical processes wherein rapid chemical action takes place, accompanied with a developement of heat, or fire, and flame.

4. *Solar Heat.*

It is well known that the solar rays, when collected by a mirror, or lens, into a focus, produce the most astonishing effects.

Dr. Herschel has discovered that there are rays emitted from the sun, which have not the power of illuminating or producing vision: and that these are the rays which produce the heat of the solar light.

Consequently, heat is emitted from the sun in rays, but these rays are not the same with the rays of light.

5. *Production of Heat by the Electric Spark, and by Galvanism.*

The effects of electricity are too well known in this point of view, to need any description.

Galvanism has of late become a powerful instrument for the purpose of exciting heat. Not only easily inflammable substances, such as phosphorus, sulphur, &c. have been fired, but likewise gold, silver, copper, tin, and the rest of the metals, have been burnt by means of galvanism.

General Effects of Heat.

Expansive property of Heat. — This is the first and most obvious effect which heat produces on bodies. Experience has taught us that, at all times, when bodies become hot, they increase in bulk. The bodies experience a dilatation which is greater in proportion to the accumulation of caloric, or, in other words, to the intensity of the heat. This is a general law, which holds good as long as the bodies have suffered no change either in their combination or in the quantity of their chemical principles.

This power, which heat possesses, consists, therefore, in a constant tendency to separate the particles of bodies. Hence philosophers consider heat as the *repulsive power* which acts upon all bodies whatever, and which is in constant opposition to the power of attraction.

The phenomena which result from these mutual actions, seem, as it were, the secret springs of nature. Heat, however, does not expand all bodies equally, and we are still ignorant of the laws which it follows.

1. *Expansion of Fluid Bodies by Heat.*

Take a glass globe, with a long slender neck (called a bolt head); fill it up to the neck with water, ardent spirit, or any other fluid which may be coloured with red or black ink, in order to be more visible, and then immerse the globe of the instrument in a vessel of hot water; the included fluid will instantly begin to mount into the neck. If it be taken out of the water and brought near the fire, it will ascend more and more, in proportion as it becomes heated; but, upon removing it from the source of heat, it will sink again: a clear proof that caloric dilates it, so as to make it occupy more space when hot than when cold. These experiments may, therefore, serve as a demonstration that heat expands *fluid* bodies.

2. *Expansion of Aëriform Bodies by Heat.*

Take a bladder partly filled with air, the neck of which is closely tied, so as to prevent the inclosed air from escaping, and let it be held near a fire. The air will soon begin to occupy more space, and the bladder will become gradually distended; on continuing the expansion of the air, by increasing the heat, the bladder will burst with a loud report.

3. *Expansion of Solid Bodies by Heat.*

If we take a bar of iron, six inches long, and put it into a fire till it becomes red-hot; and then measure it in this state accurately, it will be found 1-20th of an inch longer than it was before; that is, about 120th part of the whole. That the metal is proportionally expanded in breadth, will be seen by trying to pass it through an aperture which it fitted exactly when cold, but which will not admit it when red-hot. The bar is, therefore, increased in length and diameter.

To discover the minutest changes of expansion by heat, and the relative proportions thereof, instruments have been contrived, called *Pyrometers*, the sensibility of which is so delicate as to shew an expansion of 1-100000th of an inch.

It is owing to this expansion of metals, that the motion of time-pieces is rendered erroneous; but the ingenuity of artists has discovered methods of obviating this inaccuracy, by employing the greater expansion of one metal, to counteract the expansion of another; this is effected in what is called the grid-iron pendulum. Upon the same principle a particular construction of watches has been contrived.

The expansion of metals is likewise one of the principal reasons that clocks and watches vary in winter and summer, when worn in the pocket, or exposed to the open air, or when carried into a hotter or a colder climate. For the number of the vibrations of the pendulum is always in the sub-duplicate ratio of its length, and as the length is changed by heat and cold, the times of vibration will be also changed. The quantity of alteration, when considered in a single vibration, is exceedingly small, but when they are often repeated, it will be very sensible. An alteration of one-thousandth part in the time of a single vibration of a pendulum which beats seconds, will make a change of eighty-six whole vibrations in twenty-four hours.

As different metals expand differently with the same degree of heat; those musical instruments, whose parts are to maintain a constant true proportion, should never be strung with different metals. It is on this account that harpsichords, &c. are out of tune by a change of temperature.

Bodies which are brittle, or which want

flexibility, crack or break, if suddenly heated. This likewise depends upon the expansive force of heat, stretching the surface to which it is applied, while the other parts, not being equally heated, do not expand in the same ratio, and are therefore torn asunder or break. Hence thin vessels stand heat better than thick ones. The same holds, when they are suddenly cooled.

Measurement of Heat.

Upon the expansive property of heat, which we have considered before, is founded its artificial measurement. Various means have been employed to assist the imperfection of our sensations in judging of the different degrees of heat, for our feelings unaided afford but very inaccurate information concerning this matter; they indicate the presence of *heat*, only when the bodies presented to them are *hotter* than the actual temperature of our organs of feeling. When those bodies are precisely of the same temperature with our body, which we make the standard of comparison, we then are not sensible of the presence of heat in them. When their temperature is less than that of our bodies, their contact gives us what is called the sensation of cold.

The effects of heat upon material bodies in general, which are easily visible to us, afford more precise and determinate indications of the intensity, than can be derived from our feelings alone. The ingenuity of the philosopher and artist has therefore furnished us with instruments for measuring the relative heat or temperature of bodies. These instrumeuts are called *Thermometers* and *Pyrometers*. By these, all degrees are measurable, from the slightest, to that of the most intense heat.

1. *Nature of the Thermometer.*

A thermometer is a hollow tube of glass, hermetically sealed, and blown at one end in the shape of a hollow globe. The bulb and part of the tube are filled with mercury, which is the only fluid which expands equally. When we immerse the bulb of the thermometer in a hot body, the mercury expands, and of course *rises* in the tube; but when we plunge it into a cold body, the mercury contracts, and of course *falls* in the tube.

The rising of the mercury indicates, therefore, an increase of heat; its falling, a diminution of it; and the quantity which it rises or falls, denotes the proportion of increase or diminution. To facilitate observation, the tube is divided into a number of equal parts, called degrees.

Further, if we plunge a thermometer ever so often into melting snow or ice, it will always stand at the same point. Hence we learn that *snow* or *ice* always begins to melt at the same temperature.

If we plunge a thermometer repeatedly into water kept boiling, we find that the mercury rises up to a certain point. This is therefore the point at which water always boils, provided the pressure of the atmosphere be the same.

There are four different thermometers used at present in Europe, differing from each other in the number of degrees into which the space between the freezing and boiling points is divided. These are Fahrenheit's, Reaumur's, Celsius's, and Delisle's.

The thermometer uniformly used in Britain, is Fahrenheit's; in this the freezing point is fixed at 32° — the boiling point, at 212° above 0° — or the part at which both the ascending and descending series of numbers commence.

In the thermometer which was first constructed by Reaumur, the scale is divided into a smaller number of degrees upon the same length, and contains not more than 80° between the freezing and the boiling points. The freezing point is fixed in this thermometer precisely at 0°, the term between the ascending and the descending series of numbers. Again, 100 is the number of the degrees between the freezing and the boiling points in the scale of Celsius; which has been introduced into France, since the revolution, under the name of the Centigrade thermometer; and the freezing point is in this, as in the thermometer of Reaumur, fixed at 0°. One degree on the scale of Fahrenheit, appears, from this account, to be equal to 4-9ths of a degree on that of Reaumur, and to 5-9ths of a degree on that of Celsius.

The space in Delisle's thermometer between the freezing and boiling points is divided into 150°, but the graduation begins at the boiling point, and increases towards the freezing point. The boiling point is marked 0, the freezing point 150°. Hence 180 F : =150 D, or 6 F : =5 D. To reduce the degrees of Delisle's thermometer *under* the boiling point to those of Fahrenheit; we have F : =212−6-5 D; to reduce those *above* the boiling point F : =212+6-5 D. Upon the knowledge of this proportion it is easy for the student to reduce the degrees of any of these thermometers into the degrees of any other of them.

2. *Nature of the Pyrometer.*

To measure those higher degrees of heat to which the thermometer cannot be applied, there have been other instruments invented by different philosophers: these are called *pyrometers*. The most celebrated instrument of this kind, and which has been adopted into general use, is that invented by the late ingenious Mr. Wedgwood.

This instrument is also sufficiently simple. It consists of two pieces of brass fixed on a plate, so as to be 6-10ths of an inch asunder at one end, and 3-10ths at the other; a scale is marked upon them, which is divided into 240 equal parts, each 1-10th of an inch; and with this his gauge, are furnished a sufficient number of pieces of baked clay, which must have been prepared in a red heat, and must be of given dimensions. These pieces of clay, thus prepared, are first to be applied cold, to the rule of the gauge, that there may no mistake take place in regard to their dimensions. Then any one of them is to be exposed to the heat which is to be measured, till it shall have been completely penetrated by it. It is then removed and applied to the gauge. The difference between its former and its present dimensions, will shew how much it has shrunk; and will consequently indicate to what degree the intensity of the heat to which it was exposed amounted.

High temperatures can thus be ascertained with accuracy. Each degree of Wedgwood's pyrometer is equal to 130° of Fahrenheit's.

Exceptions to the Expansion by Heat.

Philosophers have noticed a few exceptions to the law of heat expanding bodies. For instance; water, when cooled down within about 7° of the freezing point, instead of contracting on the farther deprivation of heat, actually expands.

Another seeming exception is manifested in alumine, or clay; others occur in the case of cast-iron, and a few other metals. Alumine contracts on being heated, and cast-iron, bismuth, &c. when fully fused, are more dense than when solid; for, as soon as they become so, they decrease in density, they expand in the act of cooling, and hence the sharpness of figures upon iron which has been cast in moulds, compared to that of many other metals.

Some philosophers have persuaded themselves that these exceptions are only *apparent*, but not really true. They say when water freezes, it assumes a crystalline form, the crystals cross each other and cause numerous vacuities, and thus the ice occupies more space. The same is the case with fused iron, bismuth, and antimony. The contraction of clay is considered owing to the loss of water, of which it loses a part at every increased degree of temperature hitherto tried; there is therefore a loss of matter; and a reduction of volume must follow: but others assert, that this only happens to a certain extent.

Mr. Tilloch has published a brief examination of the received doctrines respecting heat and caloric, in which these truths are more fully considered, together with many other interesting facts relative to the received notions of heat.

Equal Distribution of Heat.

If a number of bodies of different temperatures are placed in contact with each other, they will all at a certain time acquire a temperature, which is intermediate; the caloric of the hottest body will diffuse itself among those which are heated in a less degree, till they have all acquired a certain mean temperature. Thus, if a bar of iron which has been made red-hot be kept in the open air, it does not retain the heat which it had received, but becomes gradually colder and colder, till it arrives at the temperature of the bodies in its neighbourhood. On the other hand, if we cool down the iron bar by keeping it for some time covered with snow, and then carry it into a warm room, it does not retain its low temperature, but becomes gradually hotter, till it acquires the temperature of the room. It is therefore obvious, that in the one instance the temperature is lowered, and in the other it is raised.

These changes of temperature occupy a longer or a shorter time, according to the nature of the body, but they always take place at last. This law itself is, indeed, familiar to every one: when we wish to heat a body, we carry it towards the fire: when we wish to cool it, we surround it by cold bodies.

Propagation of Heat.

We have seen, that when bodies of higher temperature than others are brought into contact with each other, the heat is propagated from the first to the second, or the colder body deprives the warmer of its excess of heat. — We shall now see that some bodies do so much more quickly than others. Through some bodies caloric passes with undiminished velocity, through others its passage is prodigiously retarded.

This disposition of bodies of admitting, under equal circumstances, the refrigeration of a heated body within a shorter or a longer time, is called *the power of conducting heat*; and a body is said to be a *better* or *worse conductor of heat*, as it allows the refrigeration to go on quicker or slower. Those bodies, therefore, which possess the property of letting heat pass with facility, are called *good conductors*, those through which it passes with difficulty are called *bad conductors*, and those through which it is supposed not to pass at all, are called *non-conductors*: thus we say, in common language, some bodies are *warm*, or capable of preserving warmth, and from this arises the great difference in the sensation excited by different bodies, when applied at the same temperature to our organs of feeling. Hence, if we immerse our hand in mercury, we feel a greater sensation of cold than when we immerse it in water, and a piece of metal appears to be much colder than a piece of wood, though their temperatures, when examined by means of the thermometer, are precisely the same.

It is probable that all solids conduct heat in some degree, though they differ very much in their conducting power. Metals are the best conductors of heat; but the conducting powers of these substances are by no means equal. Stones seem to be the next best conductors. Glass conducts heat very slowly; wood and charcoal still slower; and feathers, silk, wool, and hair, are still worse conductors than any of the substances yet mentioned.

The best conductors of electricity and galvanism are also the best conductors of heat.

Experiment. — Take a number of straight wires, of equal diameters and lengths, but of different metals; for instance, gold, silver, copper, iron, &c.; cover each of them with a thin coat of wax, or tallow, and plunge their extremities into water, kept boiling, or into melted lead. The melting of the coat of wax will shew that caloric is more quickly transmitted through some metals than others.

It is on this account also, that the end of a glass rod may be kept red-hot for a long time, or even melted, without any inconvenience to the hand which holds the other extremity; though a similar metallic rod, heated in the same manner, would very soon become too hot to be held.

Liquid and Aëriform Bodies convey Heat by an actual Change in the Situation of their Particles.

Count Rumford was the first who proved that fluids in general, and aëriform bodies, convey heat on a different principle from that observed in solids. This opinion is pretty generally admitted, though various ingenious experiments have been made by different philosophers to prove the contrary. In water, for instance, the Count has proved that caloric is propagated principally in consequence of the motion which is occasioned in the particles of that fluid.

All fluids are considered by him, strictly speaking, in a similar respect as *non-conductors* of caloric. They can receive it, indeed, from other substances, and can give it to other substances, but no particle can either receive it from or give it to another particle of the same kind. Before a fluid, therefore, can be heated or cooled, every particle must go individually to the substance from which it receives or to which it gives out caloric. Heat being, therefore, only propagated in fluids, in consequence of the internal motion of their particles, which transport the heat; the more rapid these motions are, the more rapid is the communication of heat. The cause of these motions is the change in the specific gravity of the fluid, occasioned by the change of temperature, and the rapidity is in proportion to the change of the specific gravity of the liquid by any given change of temperature. The following experiment may serve to illustrate this theory.

Take a thin glass tube, eight or ten inches long, and about an inch in diameter. Pour into the bottom part, for about the depth of one inch, a little water coloured with Brazil-wood, or litmus, and then fill up the tube with common water, extremely gently, so as to keep the two *strata* quite distinct from each other. Having done this, heat the bottom part of the tube over a lamp; the coloured infusion will then ascend, and gradually tinge the whole fluid; on the contrary if the heat be applied above, the water in the upper part of the tube may be made to boil, but the colouring matter will remain at the bottom undisturbed. The heat cannot act downwards to make it ascend.

By thus being able to make the upper part of a fluid boil without heating the bottom part, water may be kept boiling for a considerable time in a glass tube over ice, without melting it.

Other experiments, illustrating the same principle, may be found in Count Rumford's excellent Essays, especially in Essay the 7th; 1797.

To this indefatigable philosopher we are wholly indebted for the above facts: he was the first who taught us that air and water were nearly non-conductors. The results of his experiments, which are contained in the above Essay, are highly interesting; they also show that the conducting power of fluids is impaired by the admixture of fibrous and glutinous matter.

Count Rumford proved that ice melted more than 80 times slower, when boiling-hot water stood on its surface, than when the ice was placed to swim on the surface of the hot water. Other experiments showed that water, only eight degrees of Fahrenheit above the freezing point, or at the temperature of forty degrees, melts as much ice, in any given time, as an equal volume of that fluid at any higher temperature, provided the water stands on the surface of the ice. Water, at the temperature of 41°, is found to melt more ice, when standing on its surface, than boiling water. It appears however that liquids are not, as he supposes, complete non-conductors of caloric: because if heat be applied at top, it is capable of making its way downwards, through water for example, though very imperfectly and slowly.

It becomes further evident, from the Count's ingenious experiments, that of the different substances used in clothing, hares' fur and eider-down are the warmest; next to these, beavers' fur, raw silk, sheep's wool, cotton wool, and lastly, lint, or the scrapings of fine linen. In fur, the air interposed among its particles is so engaged as not to be driven away by the heat communicated thereto by the animal body; not being easily displaced, it becomes a barrier to defend the animal body from the external cold. Hence it is obvious that those skins are warmest which have the finest, longest, and thickest fur; and that the furs of the beaver, otter, and other like quadrupeds, which live much in the water, and the feathers of water-fowl, are capable of confining the heat of those animals in winter, notwithstanding the coldness of the water which they frequent. Bears, and various other animals, inhabitants of cold climates, which do not often take the water, have their fur much thicker on their backs than on their bellies.

The snow which covers the surface of the earth in winter, in high latitudes, is doubtless designed as a garment to defend it against the piercing winds from the polar regions, which prevail during the cold season.

Without dwelling farther upon the philosophy of this truth, we must briefly remark that the happy application of this law, satisfactorily elucidates some of the most interesting facts of the economy of nature.

Theory of Caloric of Fluidity, or Latent Heat.

There are some bodies which, when submitted to the action of caloric, dilate to such a degree, and the power of aggregation subsisting among their particles is so much destroyed and removed to such a distance by the interposition of caloric, that they slide over each other in every direction, and therefore appear in a fluid state. This phenomenon is called *fusion*. Bodies thus rendered fluid by means of caloric, are said to be *fused*, or *melted*; and those that are subject to it, are called *fusible*.

The greater number of solid bodies may, by the application of heat, be converted into fluids. Thus metals may be fused; sulphur, resin, phosphorus, may be melted; ice may be converted into water, &c.

Those bodies which cannot be rendered fluid by any degree of heat hitherto known, are called *infusible*.

If the effects of heat under certain circumstances, be carried still further than is necessary to render bodies fluid, vaporization begins; the bodies then become converted into the vaporous or *gaseous state*. Vaporization, however, does not always require a previous fusion. Some bodies are capable of being converted into the vaporous state, without previously becoming fluid, and others cannot be volatilized at any temperature hitherto known: the latter are termed fixed.

Fluidity is therefore by no means essential to any species of matter, but always depends on the presence of a quantity of caloric. Solidity is the natural state of all bodies, and there can be no doubt that every fluid is capable of being rendered solid by a due reduction of temperature; and every solid may be fused by the agency of caloric, if the latter does not decompose them at a temperature inferior to that which would be necessary for their fusion.

Caloric of Fluidity.

Dr. Black was the first who proved that, whenever caloric combines with a solid body, the body becomes heated only, until it is rendered fluid: and that, while it is acquiring the fluid state, its temperature remains stationary, though caloric is continued to be added to it. The same is the case when fluids are converted into the aëriform or vaporous state.

From these facts, the laws of latent heat have been inferred. The theory may be illustrated by means of the following experiments.

If a lump of ice, at a low temperature, suppose at 22°, be brought into a warm room, it will become gradually less cold, as may be discovered by means of the thermometer. After a very short time, it will reach the temperature of 32°, (the freezing point); but there it stops. The ice then begins to melt; but the process goes on very slowly. During the whole of that time its temperature continues at 32°; and as it is constantly surrounded by warm air, we have reason to believe that caloric is constantly entering into it; yet it does not become hotter till it is changed into water. Ice, therefore, is converted into water by a quantity of caloric uniting with it.

It has been found by calculation, that ice in melting absorbs 140° of caloric, the temperature of the water produced still remaining at 32°.

This fact may be proved in a direct manner. Take one pound of ice, at 32°, reduced to a coarse powder; put it into a wooden bowl, and pour over it one pound of water, heated to 172°; all the ice will become melted, and the temperature of the whole fluid, if examined by a thermometer, will be 32°; 140° of caloric are therefore lost, and it is this quantity which was requisite to convert the ice into water. This experiment succeeds better, if, instead of ice, fresh-fallen snow be employed.

This caloric has been called *latent caloric*, because its presence is not measurable by the thermometer: also more properly caloric of fluidity.

Dr. Black has also ascertained by experiment, that the fluidity of melted wax, tallow, spermaceti, metals, &c. is owing to the same cause; and Landriani proved, that this is the case with sulphur, alum, nitrate of potash, &c.

We consider it therefore as a general law, that whenever a solid is converted into a fluid, it combines with caloric, and that is the cause of fluidity.

On the sudden transition of solids into fluids, is founded the well-known

Production of Artificial Cold, by Means of Frigorific Mixtures.

A number of experiments have been lately made by different philosophers, in order to produce artificial cold. And as these methods are often employed in chemistry, with a view to expose bodies to the influence of very low temperatures, we shall enumerate the different substances which may be made use of for that purpose, and the degrees of cold which they are capable of producing. We are indebted for them to Pepys, Walker, and Lowitz.

A TABLE OF FREEZING MIXTURES.

Mixtures.		*Thermometer sinks.*
Muriate of ammonia Nitrate of potash Water	5 parts 5 16	From 50° to 10°.
Muriate of ammonia Nitrate of potash Sulphate of soda Water	5 parts 5 8 16	From 50° to 4°.
Sulphate of soda Diluted nitric acid	3 parts 2	From 50° to —3°.
Sulphate of soda Muriatic acid	8 parts 5	From 50° to 0°.
Snow Muriate of soda	1 part 1	From 32° to 0°.
Snow, or pounded ice Muriate of soda	2 parts 1	From 0° to —5°.
Snow, or pounded ice Muriate of soda Muriate of ammonia and nitrate of potash	12 parts 5 5	From —5° to —18°.
Snow or pounded ice Muriate of soda Nitrate of ammonia	12 parts 5 5	From —18° to —25°.
Snow Diluted nitric acid	3 parts 2	From 0° to —46°.
Muriate of lime Snow	3 parts 2	From 32° to —50°.
Potash Snow	4 parts 3	From 32° to —51°.
Snow Diluted sulphuric acid Diluted nitric acid	8 parts 3 3	From —10° to —56°.
Snow Diluted sulphuric acid	1 part 1	From 20° to —60°.
Muriate of lime Snow	2 parts 1	From 0° to —66°.
Muriate of lime Snow	3 parts 1	From —40° to —73°.
Diluted sulphuric acid Snow	10 parts 8	From —68° to —91°.
Nitrate of ammonia Water	1 part 1	From 50° to 4°.
Nitrate of ammonia Carbonate of soda Water	1 part 1 1	From 50° to —7°.
Sulphate of soda Muriate of ammonia Nitrate of potash Diluted nitric acid	6 parts 4 2 4	From 50° to —10°.
Sulphate of soda Nitrate of ammonia Diluted nitric acid	6 parts 5 4	From 50° to —14°.
Phosphate of soda Diluted nitric acid	9 parts 4	From 50° to —12°.
Phosphate of soda Nitrate of ammonia Diluted nitric acid	9 parts 6 4	From 50° to —21°.
Sulphate of soda Diluted sulphuric acid	5 parts 4	From 50° to 3°.

Management of the preceding Mixtures for producing Cold.

To produce the effects before stated, the salts must be reduced to powder, and contain their full quantity of water of crystallization. The vessel in which the freezing mixture is made, should be very thin, and just large enough to hold it, and the materials should be mixed together as expeditiously as possible, taking care to stir the mixture at the same time with a rod of glass or wood.

In order to obtain the full effect, the materials ought to be first cooled to the temperature marked in *the table*, by introducing them into some of the other frigorific mixtures, and then mingling them together in a similar mixture. If, for instance, we wish to produce —46°, the snow and diluted nitric acid ought to be cooled dawn to 0°, by putting the vessel which contains each of them into the fifth freezing mixture in the above table, before they are mingled together. If a more intense cold be required, the materials to produce it are to be brought to the proper temperature by being previously placed in the second freezing mixture.

This process is to be continued till the required degree of cold has been procured.

Conversion of Solids and Fluids into the Aëriform or Gaseous State.

We have seen before, that in order to render solids fluid, a certain quantity of caloric is necessary, which combines with the body, and therefore cannot be measured by the thermometer; we shall now endeavour to prove, that the same holds good in respect to the conversion of solids or fluids into the vaporous or gaseous state.

Take a small quantity of carbonate of ammonia, introduce it into a retort, the neck of which is directed under a cylinder filled with mercury and inverted in a bason of the same fluid. On applying heat to the body of the retort, the carbonate of ammonia will be volatilised, it will expel the mercury out of the cylinder, and become an invisible gas, and would remain so, if its temperature was not lowered.

The same is the case with benzoic acid, camphire, and various other substances.

All fluids may, by the application of heat, be converted into an aëriform elastic state.

When we consider water in a boiling state, we find that this fluid, when examined by the thermometer, is not hotter after boiling several hours, than when it began to boil, though to maintain it boiling a brisk fire must necessarily be kept up. What then, we may ask, becomes of the wasted caloric? It is not perceptible in the water, nor is it manifested by the steam; for the steam, if not compressed, upon examination is found not to be hotter than boiling water. The caloric is therefore absorbed by the steam, and although what is so absorbed, is absolutely necessary for the conversion of water into the form of steam; it does not increase its temperature, and is therefore not appreciable by the thermometer.

The conclusion is further strengthened by the heat given out by steam on its being condensed by cold. This is particularly manifested in the condensation of this fluid in the process of distilling, where upon examining the refrigeratory, it will be found that a much greater quantity of caloric is communicated to it, than could possibly have been transmitted by the caloric which was sensibly acting before the condensation. This may be easily ascertained by observing the quantity of caloric communicated to the water in the refrigeratory of a still, by any given quantity of liquid that passes over.

1. The boiling point, or the temperature at which the conversion of fluids into gases takes place, is different in different fluids, but constant in each, provided the pressure of the atmosphere be the same.

Put any quantity of sulphuric ether into a Florence flask, suspend a thermometer in it, and hold the flask over an Argand's lamp, the ether will immediately begin to boil, and the thermometer will indicate 98°, if the ether has been highly rectified.

If highly rectified ardent spirit is heated in a similar manner, the thermometer will rise to 176°, and there remain stationary.

If water is substituted, it will rise to 212°.

If strong nitrous acid of commerce be made use of, it will be found to boil at 248°;—sulphuric acid and linseed-oil at 600°;—mercury at 656°, &c.

2. The boiling point of fluids is raised by pressure.

Mr. Watt heated water under a strong pressure to 400°. Yet still when the pressure was removed, only part of the water was converted into vapour, and the temperature of this vapour, as well as that of the remaining fluid, was no more than 212°. There was therefore 188° of caloric suddenly lost. This caloric was carried off by the steam. Now as only about one-fifth of the water was converted into steam, that steam must contain not only its own 188°, but also the 188° lost by each of the other four parts; that is to say, it must contain 188° × 5, or about 940°. Steam, therefore, is water combined with at least 940° of caloric, the presence of which is not indicated by the thermometer.

3. When pressure is removed from the surface of bodies, their conversion into the gaseous state is greatly facilitated, or their boiling point is lowered.

In proof of this the following experiments may serve:

Let a small bottle be filled with highly rectified sulphuric ether, and a piece of wetted bladder be tied over its orifice around its neck. Transfer it under the receiver of an air-pump, and take away the superincumbent pressure of the air in the receiver. When the exhaustion is complete, pierce the bladder by means of a pointed sliding wire, passing through a collar of leather which covers the upper opening of the receiver. Having done this, the ether will instantly begin to boil, and become converted into an invisible gaseous fluid.

Take a small retort or Florence flask, fill it one half or less with water, and make it boil over a lamp; when kept briskly boiling for about five minutes, cork the mouth of the retort as expeditiously as possible, and remove it from the lamp.

The water, on being removed from the source of heat, will keep boiling for a few minutes, and when the ebullition begins to slacken, it may be renewed by dipping the retort into cold water, or pouring cold water upon it.

The water during boiling, becomes converted into vapour; this vapour expels the air of the vessel, and occupies its place; on diminishing the heat, it condenses; when the retort is stopped, a partial vacuum is formed; the pressure becomes diminished, and a less degree of heat is sufficient to cause an ebullition.

For the same reason, water may be made to boil under the exhausted receiver at 94° Fahr. or even at a lower degree; alkohol at 56°; and ether at —20°.

On the conversion of fluids into gases is founded the following experiment, by which water is frozen by means of sulphuric ether.

Take a thin glass tube four or five inches long and about two or three-eighths of an inch in diameter, and a two-ounce bottle furnished with a capillary tube fitted to its neck. In order to make ice, pour a little water into the tube, taking care not to wet the outside, nor to leave it moist. Having done this, let a stream of sulphuric ether fall through the capillary tube upon that part of it containing the water, which by this means will be converted into ice in a few minutes, and this it will do even near a fire or in the midst of summer.

If the glass tube, containing the water, be exposed to the brisk thorough air, or free draught of an open window, a large quantity of water may be frozen in a shorter time; and if a thin spiral wire be introduced previous to the congelation of the water, the ice will adhere to it, and may thus be drawn out conveniently.

A person might be easily frozen to death during very warm weather, by merely pouring upon his body for some time sulphuric ether, and keeping him exposed to a thorough draught of air.

Artificial Refrigeration.

The cooling or refrigeration of rooms in the summer season by sprinkling them with water, becomes likewise obvious on this account.

The method of making ice artificially in the East Indies depends on the same principle. The ice-makers at Benares dig pits in large open plains, the bottom of which they strew with sugar-canes or dried stems of maize or Indian-corn. Upon this bed they place a number of unglazed pans, made of so porous an earth that the water penetrates through their whole substance. These pans are filled towards evening in the winter season with water that has boiled, and left in that situation till morning, when more or less ice is found in them, according to the temperature and other qualities of the air; there being more formed in dry and warm weather, than in that which is cloudy, though it may be colder to the human body.

Every thing in this process is calculated to produce cold by evaporation; the beds on which the pans are placed, suffer the air to have a free passage to their bottoms; and the pans constantly oozing out water to their external surface, are cooled by the evaporation of it.

In Spain, they use a kind of earthen jars, called buxaros, which are only half-baked, the earth of which is so porous, that the outside is kept moist by the water which filters through it, and though placed in the sun, the water in the jar becomes as cold as ice.

It is a common practice in China to cool wine or other liquors by wrapping the bottle in a wet cloth, and hanging it up in the sun. The water in the cloth becomes converted into vapour, and thus cold is produced.

The Blacks in Senegambia have a similar method of cooling water by filling tanned leather bags with it, which they hang up in the sun; the water oozes more or less through the leather so as to keep the outward surface wet, which by its quick and continued evaporation cools the water remarkably.

The winds on the borders of the Persian Gulph are often so scorching, that travellers are suddenly suffocated unless they cover their heads with a wet cloth; if this be too wet, they immediately feel an intolerable cold, which would prove fatal if the moisture was not speedily dissipated by the heat.

Condensation of Vapour.

If a cold vessel is brought into a warm room, particularly where many people are assembled, the outside of it will soon become covered with a sort of dew.

Before some changes of weather, the stone pavements, the walls of a house, the balustrades of staircases and other solid objects, feel clammy and damp.

In frosty nights, when the air abroad is colder than the air within, the dampness of this air, for the same reason, settles on the glass panes of the windows, and is there frozen into curious and beautiful figures.

Thus *fogs* and *dews* take place, and in the higher regions *clouds* are formed from the condensed vapour. The still greater condensation produces *mists* and *rain*.

Capacity of Bodies for containing Heat.

The property which different bodies possess, of containing at the same temperature, and in equal quantities, either of mass or bulk, unequal quantities of heat, is called their capacity for heat. The capacities of bodies for heat are therefore considered as great or small in proportion as their temperatures are either raised by the addition, or diminished by the deprivation, of equal quantities of heat, in a less or a greater degree.

In homogeneous bodies, the quantities of caloric which they contain are in the ratio of their temperature and mass: when therefore equal quantities of water, of oil, or of mercury, of unequal temperatures, are mingled together, the temperature of the whole will be the *arithmetical* mean between the temperatures of the two quantities that had been mixed together. It is a self-evident truth that this should be the case, for the particles of different portions of the same substance being alike, their effects must be equal. For instance:

Mix a pound of water at 172° with a pound at 32°, half the excess of heat in the hot water will quit it to go over into the colder portion; thus the hot water will be cooled 70°, and the cold will receive 70° of temperature; therefore $172-70$, or $32+70=102$ will give the heat of the mixture. To attain the arithmetical mean very exactly, several precautions however are necessary.

When heterogeneous bodies of different temperatures are mixed together, the temperature produced is never the arithmetical mean of the two original temperatures.

In order to ascertain the comparative quantities of heat of different bodies, equal weights of them are mingled together; the experiments for this purpose being in general more easily executed than those by which they are compared from equal bulks.

Thus, if one pound of mercury heated to 110° Fahr., be added to one pound of water of 44°, the temperature of the blended fluids will not be changed to 77°, as it would be if the surplus of heat were divided among those fluids in the proportion of their quantities. It will be found, on examination, to be only 47°.

On the contrary, if the pound of mercury be heated to 44°, and the water to 110°, then on stirring them together, the common temperature will be 107°.

Hence, if the quicksilver loses by this distribution 63° of caloric, an equal weight of water gains only 3° from this loss of 63° of heat. And on the contrary, if the water loses 3°, the mercury gains 63°.

When, instead of comparing the quantities of caloric which equal *weights* of different bodies contain, we compare the quantities contained in equal *volumes*, we still find that an obvious difference takes place. Thus it is found by experiment, that the quantity of caloric necessary to raise the temperature of a given volume of water any number of degrees, is, to that necessary to raise an equal volume of mercury, the same number of degrees as 2 to 1. This is therefore the proportion between the comparative quantities of caloric which these two bodies contain, estimated by their volumes; and similar differences exist with respect to every other kind of matter.

From the nature of the experiments by which the quantities of caloric which bodies contain are ascertained, it is evident that we discover merely the *comparative*, not the *absolute* quantities. Hence water has been chosen as a standard, to which other bodies may be referred; its capacity is stated as the arbitrary term of 1000, and with this the capacities of other bodies are compared.

It need not be told that pains have been taken to estimate on these experiments that portion of heat which diffuses itself into the air, or into the vessel where the mercury and water are blended together. As however such valuations cannot be made with complete accuracy, the numbers stated above are only an approximation to truth.

Radiation of Caloric.

Caloric is thrown off or radiates from heated bodies in right lines, and moves through space with inconceivable velocity. It is retarded in its passage by atmospheric air, by colourless fluids, glass, and other transparent bodies.

If a glass mirror be placed before a fire, the mirror transmits the rays of light, but not the rays of heat.

If a plate of glass, talc, or a glass vessel filled with water be suddenly interposed between the fire and the eye, the rays of light pass through it, but the rays of caloric are considerably retarded in its passage; for no heat is perceived until the interposed substance is saturated with heat, or has reached its *maximum*. It then ceases to intercept the rays of caloric, and allows them to pass as freely as the rays of light.

It has been lately shown by Dr. Herschel, that the rays of caloric are refrangible, but less so than the rays of light; and the same philosopher has also proved by experiment, that it is not only the rays of caloric emitted by the sun, which are refrangible, but likewise the rays emitted by common fires, by candles, by heated iron, and even by hot water.

Whether the rays of caloric are differently refracted, in different mediums, has not yet been ascertained. We are certain however, that they are refracted by all transparent bodies which have been employed as burning glasses.

The rays of caloric are also reflected by polished surfaces, in the same manner as the rays of light.

This was long ago noticed by Lambert, Saussure, Scheele, Pictet, and lately by Dr. Herschel.

Professor Pictet placed two concave metallic mirrors opposite to each other, at the distance of about twelve feet. When a hot body, an iron bullet for instance, was placed in the focus of the one, and a mercurial thermometer in that of the other, a substance radiated from the bullet; it passed with incalculable velocity through the air, it was reflected from the mirrors, it became concentrated, and influenced the thermometer placed in the focus, according to the degree of its concentration.

An iron ball two inches in diameter, heated so that it was not luminous in the dark, raised the thermometer not less than ten and a half degrees of Reaumur's scale, in six minutes.

A lighted candle occasioned a rise in the thermometer nearly the same.

A Florence flask containing two ounces and three drachms of boiling water, raised Fahrenheit's thermometer three degrees. He blackened the bulb of his thermometer, and found that it was more speedily influenced by the radiation than before, and that it rose to a greater height.

M. Pictet discovered another very singular fact; namely, the *apparent radiation of cold.* When, instead of a heated body, a Florence flask full of ice or snow is placed in the focus of one of the mirrors, the thermometer placed in the focus of the other immediately descends, and ascends again whenever the cold body is removed.

This phenomenon may be explained on the supposition, that from every body at every temperature caloric radiates, but in less quantity as the temperature is low; so that in the above experiment, the thermometer gives out more caloric by radiation, than it receives from the body in the opposite focus, and therefore its temperature is lowered. Or, as Pictet has supposed, when a number of bodies near to each other have the same temperature, there is no radiation of caloric, because in all of them it exists in a state of equal tension; but as soon as a body at an inferior temperature is introduced, the balance of tension is broken, and caloric begins to radiate from all of them, till the temperature of that body is raised to an equality with theirs. In the above experiment therefore, the placing the snow or ice in the focus of the mirror causes the radiation of caloric *from* the thermometer, and hence the diminution of temperature which it suffers.

These experiments have been since repeated by Dr. Young and Professor Davy, at the theatre of the Royal Institution. These gentlemen inflamed phosphorus by reflected caloric; and proved that the heat thus excited, was very sensible to the organs of feeling.

It is therefore evident, that caloric is thrown off from bodies in rays, which are invisible, or incapable of exciting vision, but which are capable of exciting heat.

These invisible rays of caloric are propagated in right lines, with extreme velocity; and are capable of the laws of reflection and refraction.

The heating agency however is different in the different coloured rays of the prismatic spectrum. According to Dr. Herschel's experiments, it follows inversely the order of the refrangibility of the rays of light. The least refrangible, possessing it in the greatest degree.

Sir Henry Englefield has lately made a series of experiments on the same subject, from which we learn, that a thermometer having its ball blackened, rose when placed in the *blue* ray of the prismatic spectrum in 3′ from 55° to 56°; in the *green*, in 3′ from 54° to 58°; in the *yellow*, in 3′ from 56° to 62°; in the *full red* in 2½′ from 56° to 72°; in the *confines of the red*, in 2½′ from 58° to 73½°; and *quite out of the visible light*, in 2½′ from 61° to 79°.

Between each of the observations, the thermometer was placed in the shade so long as to sink it below the heat to which it had risen in the preceding observation, of course its rise above that point could only be the effect of the ray to which it was exposed. It was continued in the focus long after it had ceased to rise; therefore the heats given are the greatest effects of the several rays on the thermometer in each observation. A thermometer placed constantly in the shade near the apparatus, was found scarcely to vary during the experiments.

Sir Henry made other experiments with thermometers with naked balls, and with others whose balls were painted white, for which we refer the reader to the interesting paper of the Baronet, from which the above experiments are transcribed.

The coloured rays emitted from the sun, and combustible bodies, since they excite heat and vision, must consist of a mixture of heat-making rays, and rays of light.

And as the rays of heat and light accompany each other, when emitted from luminous bodies, the velocity with which the rays of caloric move, must be equal to that of light, and hence its particles must be equally minute. They differ however in this particular, that the rays of light produce the sensation of vision, and possess certain chemical properties, whilst in those of caloric the peculiar agency of heat resides.

CALORI′METER. An instrument by which the whole quantity of absolute heat existing in a body in chemical union can be ascertained.

CA′LTHA. (Καλθα, corrupted from χαλχα, yellow, from whence, says Vossius, come calthula, caldula, caledula, calendula.) Marsh marigold.

1. The name of a genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Polygynia.*

2. The pharmacopœial name of the herb wild marigold, so called from its colour.

Ca′ltha arve′nsis. *Calendula arvensis. Caltha vulgaris.* The wild marigold is sometimes preferred to the garden marigold. Its juice is given, from one to four ounces, in jaundice and cachexia; and the leaves are commended as a salad for children afflicted with scrophulous humours.

Ca′ltha palu′stris. Common single marsh marigold. It is said to be caustic and deleterious: but this may be questioned. The young buds of this plant make, when properly pickled, very good substitutes for capers.

Ca′ltha vulga′ris. See *Caltha arvensis.*

Ca′lthula. The caltha is so called.

Caltrops. See *Trapa natans.*

CALU′MBA. The name now adopted by the London college of physicians for the columbo. *Colombo. Calomba. Colomba.* The root formerly so called, is now termed *Calumbæ radix* in the London pharmacopœia. It is imported from Colomba, in Ceylon, in circular, brown knobs, wrinkled on their outer surface, yellowish within, and consisting of cortical, woody, and medullary laminæ. Its smell is aromatic; its taste pungent, and very bitter. From Dr. Percival's experiments on the root, it appears that rectified spirit of wine extracts its virtues in the greatest perfection. The watery infusion is more perishable than that of other bitters. An ounce of the powdered root, half an ounce of orange-peel, two ounces of brandy, and fourteen ounces of water, macerated 12 hours without heat, and then filtered through paper, afford a sufficiently strong and tolerably pleasant infusion. The extract made first by spirit and then with water, and reduced by evaporation to a pilular consistence, is found to be equal, if not superior in efficacy, to the powder. As an antiseptic, Calumba root is inferior to the bark; but, as a corrector of putrid bile, it is much superior to the bark; whence also it is probable, that it would be of service in the West-India yellow fever. It also restrains alimentary fermentation, without impairing digestion; in which property it resembles mustard. It does not appear to have the least heating quality, and therefore may be used in phthisis pulmonalis, and in hectic cases, to strengthen digestion. It occasions no disturbance, and agrees very well with a milk diet, as it abates flatulence, and is indisposed to acidity. The London, Edinburgh, and Dublin colleges, direct a tincture of Calumba root. The dose of the powdered root is as far as half a drachm, which, in urgent cases, may be repeated every third or fourth hour.

Ca′lva. (From *calvus,* bald.) The scalp or upper part of the cranium or top of the head; so called because it often grows bald first.

CALVA′RIA. (From *calvus,* bald.) The upper part of the cranium which becomes soon bald. It means all above the orbits, temples, ears and occipital eminence.

Calvi′ties. (From *calvus,* bald.) *Calvitium.* Baldness; want or loss of hair, particularly upon the sinciput.

CALX. (-*cis,* fœm. from *kalah,* to burn. Arab.) 1. Chalk. Limestone.

2. Lime. *Calx viva.* The London College direct it to be prepared thus: — Take of limestone one pound: break it into small pieces, and heat it in a crucible, in a strong fire, for an hour, or until the carbonic acid is entirely driven off, so that on the addition of acetic acid, no bubbles of gas shall be extricated. Lime may be made by the same process from oyster-shells previously washed in boiling water, and cleared from extraneous matters. See *Lime.*

Ca′lcis li′quor. Solution of lime, formerly called *aqua calcis.* Lime-water. "Take of lime, half a pound; boiling distilled water, twelve pints. Pour the water upon the lime, and stir them together; next cover the vessel immediately, and let it stand for three hours; then keep the solution upon the remaining lime in stopped glass bottles, and pour off the clear liquor when it is wanted for use."

Lime is soluble in about 450 times its weight of water, or little more than one grain in one fluid-ounce. It is given internally, in doses of two ounces and upwards, in cardialgia, spasms, diarrhœa, &c. and in proportionate doses in convulsions of children arising from acidity, or ulcerated intestines, intermittent fevers, &c. Externally it is applied to burns and ulcers.

Ca′lcis mu′rias. *Calx salita. Sal ammoniacus fixus.* Muriate of lime. "Take of the salt remaining after the sublimation of subcarbonate of ammonia two pounds, water a pint; mix and filter through paper. Evaporate the salt to dryness: and preserve it in a closely stopped vessel." This preparation is exhibited with the same views as the muriate of barytes. It possesses deobstruent, diuretic, and cathartic virtues, and is much used by the celebrated Fourcroy against scrophula, and other analogous diseases. Six, twelve, and twenty grains, are given to children three times a day, and a drachm to adults.

Ca'lcis muria'tis li'quor. "Take of muriate of lime two ounces, distilled water three fluid-ounces; dissolve the salt in the water, and filter it through paper."

Calx antimo'nii. See *Antimonii oxydum.*

Calx cum ka'li pu'ro. The preparation formerly called by this name, is now termed, in the London pharmacopœia, potassa cum calce.

Calx hydra'rgyri a'lba. See *Hydrargyrum præcipitatum album.*

Calx viva. See *Calx.*

Caly'pter. (From καλυπτω, to hide.) A carneous excrescence covering the hemorrhoidal vein.

Ca'mara. (From καμαρα, a vault.) *Camarium.* The fornix of the brain: also the vaulted part of the auricle of the heart.

Cama'rium. (From Καμαρα, a vault.) See *Camara.*

Camaro'ma. (From καμαρα, a vault.) *Camarosis. Camaratio.* A fracture of the skull, in the shape of an arch or vault.

Ca'mbing. A tree of the Molucca islands, whose bark has been recommended in dysenteries.

Cambirea. So Paracelsus calls the venereal bubo.

Ca'mbium. (From *cambio,* to exchange.) That nutritious humour which is changed into the matter of which the body is composed.

Cambo'dia. See *Stalagmitis.*

Cambo'gia. (From the province of *Cambaya,* in the East Indies; called also *Cambodja* and *Cambogia;* hence it has obtained its names of *Cambodia. Cambogium. Gambogia. Gambogium.*) See *Stalagmitis.*

Cambo'gia gu'tta. See *Stalagmitis.*

Cambo'gium. (From the province of Cambogia, whence it was brought.) See *Stalagmitis.*

Cambro-brita'nnica. See *Rubus Chamæmorus.*

Cambu'ca. *Cambuta membrata.* So Paracelsus calls the venereal cancer. Also by some it is described as a bubo, an ulcer, an abscess on the pudenda; also a boil in the groin.

Ca'mbui. The wild American myrtle of Piso and Margrave, which is said to be astringent.

Camel's hay. See *Andropogon Schœnanthus.*

CA'MERA. Chamber or cavity. The chambers of the eye are termed cameræ.

Camera'tio. See *Camaroma.*

Ca'mes. *Camet.* Silver.

Cami'nga. See *Canella alba.*

Ca'minus. A furnace and its chimney. In Rulandus it signifies a bell.

Cami'sia fœ'tus. (From the Arabic term *kamisah,* an under garment.) The shirt of the fœtus. It is frequently put for the chorion.

Ca'momile. See *Anthemis nobilis.*

Ca'momile, stinking. See *Anthemis cotula.*

Camomi'lla. Corrupted from chamæmelum.

Ca'mmorum. (καμμορον, *quia homines,* κακῳ μορῳ, *perimat;* because if eaten, it brings men to a miserable end.) A species of monkshood. See *Aconitum.*

Campa'na. A bell. In Chemistry, a receptacle like a bell, for making sulphuric acid; thus the oleum sulphuris per campanam.

CAMPA'NULA. (From *campana,* a bell, named from its shape.) The bell-flower. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

Ca'mpe. (From καμπτω, to bend.) A flexure or bending. It is also used for the ham, and a joint, or articulation.

Campea'chy wood. See *Hæmatoxylon Campechianum.*

Campeche'nse li'gnum. See *Hæmatoxylon Campechianum.*

CAMPER, Peter, was born at Leyden in 1722, where he studied under Boerhaave, and took his degree in medicine. He then travelled for some years, and was afterwards appointed a professor successively at Franeker, Amsterdam, and Groningen. He was subsequently occupied in prosecuting his favourite studies, in visiting various parts of Europe, by the different societies of which he was honourably distinguished, and in performing many public duties in his own country, being at length chosen one of the council of state. He died in 1789 of a pleurisy. He published some improvements in midwifery and surgery, but anatomy appears to have been his favourite pursuit. He finished two parts of a work of considerable magnitude and importance, in which the healthy and morbid structure of the arm, and of the pelvis, are exhibited in very accurate plates, from drawings made by himself: which he appears to have purposed extending to the other parts of the body. There are also some posthumous works of Camper possessing great merit, partly on subjects of natural history, partly evincing the connection between anatomy and painting; in which latter judicious rules are laid down for exhibiting the diversity of features in persons of various countries and ages, and representing the different emotions of the mind in the countenance, also for delineating the general forms of other animals, which he shews to be modified according to their economy.

Ca'mphire. See *Laurus camphora.*

Ca'mphor. See *Laurus camphora.*

CA'MPHORA. (*Camphura,* Arab.

The antients by camphor meant what now is called asphaltum, or Jews' pitch; καφουρα.) See *Laurus camphora*.

Ca'mphoræ flo'res. The subtile substance which first ascends in subliming camphor. It is nothing more than the camphor.

Ca'mphoræ flo'res compo'siti. Camphor sublimed with benzoin.

CA'MPHORAS. A salt formed by the union of the camphoric acid with different bases: thus *camphorate of alumine, camphorate of ammonia*, &c.

Camphora'sma. (From *camphora*; so called from its camphor-like smell.) Turkey balsam. See *Dracocephalum*.

Camphora'ta. See *Camphorosma*.

Camphora'tum o'leum. A mixture of olive oil, two parts, with one of camphor: of use in inflammatory swellings of the throat, if mixed with a proper cataplasm and applied to it. In ascites, when the abdomen is much distended, if rubbed on freely every night and morning, it is supposed to be useful.

CAMPHORIC ACID. *Acidum camphoricum*. If nitric acid be distilled several times (six or eight) from camphor, a crystallized salt is obtained, called the acid of camphor, which reddens syrup of violets and the tincture of turnsole. Its taste is bitter, and it differs from oxalic acid, in not precipitating lime from the muriatic acid. The union of this acid with different bases forms what are called *camphorates*, none of which have yet been used medicinally.

CAMPHORO'SMA. (From *camphora*, and οσμη, smell; so called from its smelling of camphire.) The camphor-smelling plant.

1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*. Order, *Monogynia*.

2. The pharmacopœial name of the camphorata. See *Camphorosma Monspeliensis*.

Camphorosma Monspeliensis. The systematic name of the plant called camphorata in the pharmacopœias. *Chamæpeuce. Camphorata hirsuta. Camphorosma Monspeliaca.* Stinking ground-pine. This plant, *Camphorosma Monspeliensis; foliis hirsutis linearibus*, of Linnæus, took its name from its smell resembling so strongly that of camphor: it has been exhibited internally, in form of decoction, in dropsical and asthmatic complaints, and by some is esteemed in fomentations against pain. It is rarely, if ever, used in modern practice.

Ca'mpter. (From καμπτω, to bend.) An inflexion or incurvation.

Ca'mpulum. (From καμπτω, to twist about.) A distortion of the eyelids or other parts.

Campylo'tis. (From καμπυλος, bent.) A preternatural incurvation, or recurvation of a part; also, a distortion of the eyelids.

Ca'mpylum. See *Campylotis*.

Ca'nabil. A sort of medicinal earth.

Canabi'na aquatica. See *Bidens*.

Ca'nabis I'ndica. See *Bangue* and *Cannabis*.

Ca'nabis peregri'na. See *Cannabis*.

Ca'nada balsam. See *Pinus Balsamea*.

Canade'nsis. (Brought from *Canada*.) A name of a balsam. See *Pinus balsamea*.

CANA'LES SEMICIRCULA'RES. Semicircular canals. There are three in each ear placed in the posterior part of the labyrinth. They open by five orifices into the vestibulum. See *Ear*.

Canali'culus. (Dim. of *canalis*, a channel.) A little canal. See *Canalis arteriosus*.

CANA'LIS. (From χανος, an aperture, or rather from *canna*, a reed.) A canal. A hollow round instrument like a reed, for embracing and holding a broken limb. The hollow of the spine. Also it is specifically applied to many parts of the body; as *canalis venosus*.

CANA'LIS ARTERIO'SUS. *Canaliculus arteriosus. Canalis Botalii.* A blood-vessel peculiar to the fœtus, disappearing after birth; through which the blood passes from the pulmonary artery into the aorta.

CANA'LIS NASA'LIS. A canal going from the internal canthus of the eye downwards into the nose: it is situated in the superior maxillary bone, and is lined with the pituitary membrane continued from the nose.

CANA'LIS PETITIA'NUS. A triangular cavity, naturally containing a moisture, between the two laminæ of the hyaloid membrane of the eye, in the anterior part, formed by the separation of the anterior lamina from the posterior. It is named after its discoverer, M. Petit.

Cana'lis semispetros. The half bony canal of the ear.

CANA'LIS VENO'SUS. A canal peculiar to the fœtus, disappearing after birth, that conveys the maternal blood from the *porta* of the liver to the ascending *vena cava*.

Cana'ry balm. See *Dracocephalum*.

Ca'ncamum Græco'rum. See *Hymenæa Courbaril*.

CANCE'LLI. Lattice-work; generally applied to the reticular substance in bones.

Cance'llus. (From *cancer*, a crab.) The wrong heir. Bernard the hermit. A species of cray-fish supposed to cure rheumatism, if rubbed on the part.

CA'NCER. (From καρκινος, a crab; so called by the antients, because it exhibited large blue veins like crab's claws.)

1. The name of a crab fish, from which the *chelæ cancrorum*, and *oculi cancrorum*, or *lapides cancrorum* are produced. The shell fish so called is the *Cancer astacus* of Linnæus: the officinal preparations are nevertheless obtained also from the *cancer gammarus, maeurus*, and *pagurus* of Linnæus.

Crab's claws and crab's eyes, as they are called, which are concretions found in the stomach, are of a calcareous quality, and possess antacid virtues. They are exhibited with their compounds in pyrosis, diarrhœa, and infantile convulsions from acidity.

2. The name of a disease likewise called *Carcinoma, carcinos* by the Greeks, *Lupus* by the Romans, because it eats away the flesh like a wolf. Dr. Cullen places this genus of disease in the class *locales,* and order *tumores.* He defines it a painful scirrhous tumour, terminating in a fatal ulcer. Any part of the body may be the seat of cancer, though the glands are most subject to it. It is distinguished according to its stages into *occult* and *open*; by the former is meant its scirrhous state, which is a hard tumour that sometimes remains in a quiet state for many years. When the cancerous action commences in it, it is attended with frequent shooting pains: the skin that covers it, becomes discoloured, and ulceration sooner or later takes place: when the disease is denominated *open* cancer. Mr. Pearson says, " When a malignant scirrhus or a watery excrescence, hath proceeded to a period of ulceration, attended with a constant sense of ardent and occasionally shooting pains, is irregular in its figure, and presents an unequal surface; if it discharges sordid, sanious or fetid matter; if the edges of the sore be thick, indurated, and often exquisitely painful, sometimes inverted, at other times retorted, and exhibit a serrated appearance; and should the ulcer in its progress be frequently attended with hæmorrhage, in consequence of the erosion of blood-vessels; there will be little hazard of mistake in calling it a cancerous ulcer." In men, a cancer most frequently seizes the tongue, mouth, or penis; in women, the breasts or the uterus, particularly about the cessation of their periodical discharges; and in children, the eyes. The following description of Scirrhus and Cancer, from the above writer, will serve to elucidate the subject. A hard unequal tumour that is indolent and without any discoloration in the skin, is called a scirrhus; but when an itching is perceived in it, which is followed by a pricking, shooting, or lancinating pain, and a change of colour in the skin, it is usually denominated a cancer. It generally is small in the beginning, and increases gradually; but though the skin changes to a red or livid appearance, and the state of the tumour from an indolent to a painful one, it is sometimes very difficult to say when the scirrhus really becomes a cancer, the progress being quick or slow according to concurring causes. When the tumour is attended with a peculiar kind of burning, shooting pains, and the skin hath acquired the dusky purple or livid hue, it may then be deemed the malignant scirrhus or *confirmed cancer.* When thus far advanced in women's breasts, the tumour sometimes increases speedily to a great size, having a knotty unequal surface, more glands becoming obstructed, the nipple sinks in, turgid veins are conspicuous, ramifying around and resembling a crab's claws. These are the characteristics of an occult cancer on the external parts; and we may suspect the existence of one internally when such pain and heat as has been described, succeed in parts where the patient hath before been sensible of a weight and pressure, attended with obtuse pain. A cancerous tumour never melts down in suppuration like an inflammatory one; but when it is ready to break open, especially in the breast, it generally becomes prominent in some minute point, attended with an increase of the peculiar kind of burning, shooting pain, felt before at intervals, in a less degree and deeper in the body of the gland. In the prominent part of the tumour, in this state, a corroding ichor sometimes transudes through the skin, soon forming an ulcer: at other times a considerable quantity of a thin lymphatic fluid tinged with blood from eroded vessels is found on it. Ulcers of the cancerous nature discharge a thin, fetid, acrid sanies, which corrodes the parts, having thick dark-coloured retorted lips; and fungous excrescences frequently rise from these ulcers, notwithstanding the corrosiveness of the discharge. In this state they are often attended with excruciating, pungent, lancinating, burning pains, and sometimes with bleeding.

Though a scirrhus may truly be deemed a cancer, as soon as pain is perceived in it, yet every painful tumour is not a cancer; nor is it always easy to say whether a cancer is the disorder or not: irregular hard lumps may be perceived in the breast; but on examining the other breast, where no uneasiness is perceived, the same kind of tumours are sometimes found, which renders the diagnostic uncertain. Yet in every case after the cessation of the catamenia, hard unequal tumours in the breast are suspicious; nor, though without pain, are they to be supposed indolent or innoxious.

In the treatment of this disease our chief reliance must be on extirpating the part affected. Some have attempted to dispel the scirrhous tumour by leeches, and various discutient applications, to destroy it by caustics, or to check its progress by narcotics; but without material success. Certainly, before the disease is confirmed, should any inflammatory tendency appear, antiphlogistic means may be employed with propriety; but afterwards the operation should not be delayed: nay where the nature of the tumour is doubtful, it will be better to remove it, than incur the risk of this dreadful disease. Some surgeons indeed have contested the utility of the operation; and no doubt the disease will sometimes appear again; from constitutional tendency, or from the whole not having been removed: but the balance of evidence is in favour of the operation being successful, if performed early and to an adequate extent. The plan of destroying the part by caustic is much more tedious, painful, and uncertain. When the disease has arisen from some accident, not spontaneously, when the patient is otherwise healthy, when no symptoms of malignancy in the cancer have appeared, and the adjacent glands and absorbents seem unaffected, we have stronger expectation of success: but unless all the morbid parts can be removed without the risk of dividing important nerves or arteries, it should scarcely be attempted. In operating it is advisable; 1. To make the external wound sufficiently large, and nearly in the direction of the subjacent muscular fibres. 2. To save skin enough to cover it, unless diseased. 3. To tie every vessel, which might endanger subsequent hæmorrhage. 4. To keep the lips of the wound in contact, not interposing any dressing, &c. 5. To preserve the parts in an easy and steady position for some days, before they are inspected. 6. To use only mild and cooling applications during the cure. Supposing however the patient will not consent to an operation, or circumstances render it inadmissible, the uterus for example being affected, internal remedies may somewhat retard its progress, or alleviate the sufferings of the patient: those, which have appeared most beneficial, are, 1. Arsenic, in very small doses long continued. 2. Conium, in doses progressively increased to a considerable extent. 3. Opium. 4. Belladonna. 5. Solanum. 6. Ferrum ammoniatum. 7. Hydrargyri oxymurias. 8. The juice of the galium aparine. When the part is external, topical applications may be useful to alleviate pain, cleanse the sore, or correct the fœtor; especially, 1. Fresh-bruised hemlock leaves. 2. Scraped young carrots. 3. The fermenting poultice. 4. Finely levigated chalk. 5. Powdered charcoal. 6. Carbonic acid gas, introduced into a bladder, confined round the part. 7. A watery solution of opium. 8. Liquid tar, or tar water. But none of these means can be relied upon for effecting a cure.

Ca′ncer a′stacus. The systematic name of the fish from which the crab's claws are obtained. See *Cancer.*

Ca′ncer mundito′rum. Chimney sweeper's cancer.

Ca′nchrys. *Cachrys. Libanotis.* Galen says it sometimes means parched barley.

Cancre′na. Paracelsus uses this word instead of gangræna.

Cancro′rum che′læ. Crab's claws. See *Carbonas calcis,* and *Cancer.*

Cancro′rum o′culi. See *Carbonas calcis,* and *Cancer.*

Ca′ncrum o′ris. (From *cancer,* a spreading ulcer.) Canker of the mouth; called also aphthæ serpentes, gangræna oris, &c. See *Aphthæ.*

Cande′la. (From *candeo,* to shine.) A candle.

Cande′la fuma′lis. A candle made of odoriferous powders and resinous matters, to purify the air and excite the spirits.

Cande′la re′gia. See *Verbascum.*

Candela′ria. (From *candela,* a candle, so called from the resemblance of its stalks to a candle.) The herb mullein. See *Verbascum.*

Ca′ndy ca′rrot. See *Athamanta Cretensis.*

Cane′la. Sometimes used by the antients for cinnamon, or rather cassia.

CANE′LLA. (*Canella,* dim. of *canna,* a reed; so named because the pieces of bark are rolled up in the form of a reed.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria.* Order, *Monogynia.* The canella-tree.

CANE′LLA A′LBA. The pharmacopœial name of the laurel-leaved canella. *Cortex Winteranus spurius. Canella Cubana. Winterania Canella* of Linnæus. The tree which produces the bark so called, is a native of the West Indies. It is brought into Europe in long quills, somewhat thicker than cinnamon; their taste is moderately warm, aromatic, and bitterish; and of an agreeable smell, somewhat resembling that of cloves. Canella alba has been supposed to possess considerable medicinal powers in the cure of scurvy and some other complaints. It is now merely considered as a useful and cheap aromatic, and is chiefly employed for the purpose of correcting, and rendering less disagreeable the more powerful and nauseous drugs; with which view it is used in the *tinctura amara, vinum amarum, vinum rhæi,* &c. of the Edinburgh Pharmacopœia.

Ca′nella Cuba′na. See *Canella alba.*

Ca′nella cuu′rdo. The true cinnamon-tree.

Cane′llæ Malaba′ricæ co′rtex. See *Laurus cassia.*

Canelli′fera Malaba′rica. See *Laurus cassia.*

Caneon. (From καννη, because it was made of split cane.) A sort of tube or instrument, mentioned by Hippocrates, for conveying the fumes of antihysteric drugs into the womb.

Ca′nica. A spice used in the island of Cuba, probably the pimento; or from some of the species of myrrhs.

Ca′nicæ. (From *canis.*) Coarse meal, was so called by the antients, from *canis,* a dog, because it was food for dogs. Hence *panis caniceus,* very coarse bread.

Canici′da. (From *canis,* a dog, and *cædo,* to kill; so called because dogs are destroyed by eating it.) The herb dog's bane, or aconitum. See *Aconitum.*

Canici′dium. (From *canis*, a dog, and *cædo*, to kill.) The anatomical dissection of living dogs.

Cani′na bra′ssica. The *mercurialis sylvestris* of Linnæus.

Cani′na li′ngua. The cynoglossum.

Cani′na ma′lus. The mandragora.

Cani′na ra′bies. The hydrophobia.

Canine. Whatever partakes of, or has any relation to the nature of a dog.

Canine appetite. See *Bulimia.*

Canine madness. See *Hydrophobia.*

CANINE TEETH. *Dentes canini. Cynodontes. Cuspidati* of Mr. John Hunter; because they have the two sides of their edge sloped off to a point, and this point is very sharp or cuspidated. *Columellares* of Varro and Pliny. The four eye-teeth are so called from their resemblance to those of the dog. They are situated, two in each jaw, on the side of the four middle or incisor teeth. Their fangs are longer than those of the incisores, and therefore from the fangs of those in the upper jaw being supposed to extend the greatest part of the way to the eye, they have been called the *eye-teeth.*

Cani′nus. (*Caninus*, sc. *musculus*; because it arises near the canine or eye-tooth.) See *Levator anguli oris.*

Cani′nus se′ntis. (From *canis*, a dog, and *sentis*, a thorn; from its being prickly like a thorn.) See *Rosa canina.*

Cani′ram. (Indian.) See *Strychnos nux vomica.*

Caniru′bus. (From *canis*, and *rubus*, a bramble.) See *Rosa canina.*

CA′NIS. A dog. The white dung of this animal, called *album græcum*, was formerly in esteem, but now disused.

This term was also applied to the frænum of the penis.

Ca′nis interfe′ctor. Indian caustic barley or cevadilla.

Ca′nis po′nticus. See *Castor.*

Ca′nna. (Heb.) A reed or hollow cane.

A name of the fibula from its resemblance to a reed.

Ca′nna fi′stula. See *Cassia fistula.*

Ca′nna I′ndica. The *Sagittaria alexipharmica.*

Ca′nna ma′jor. The tibia.

Ca′nna mi′nor cru′ris. A name formerly applied to the fibula.

Cannabi′na. (From *canna*, a reed; named from its reed-like stalk.) So Tournefort named the Datisca.

CA′NNABIS. (From *καννα*, a reed. Κανναϐοι are foul springs, wherein hemp, &c. grow naturally. Or from *kanaba*, from *kanah*, to mow. Arab.) Hemp.

1. The name of a genus of plants in the Linnæan system. Class, *Diœcia.* Order, *Pentandria.*

2. The pharmacopœial name of the hemp plant.

Ca′nnabis sati′va. The systematic name of the hemp plant. It has a rank smell of a narcotic kind. The effluvia from the fresh herb are said to affect the eyes and head, and that the water in which it has been long steeped is a sudden poison. Hemp-seeds, when fresh, afford a considerable quantity of oil. Decoctions and emulsions of them have been recommended against coughs, ardor urinæ, &c. Their use, in general, depends on their emollient and demulcent qualities. The leaves of an oriental hemp, called *bang* or *bangue*, and by the Egyptians *assis*, are said to be used in Eastern countries, as a narcotic and aphrodisiac. See *Bangue.*

Canna′corus radi′ce cro′cea. See *Curcuma.*

CA′NNULA. (Dim. of *canna*, a reed.) The name of a surgical instrument. See *Canula.*

Ca′non. (Κανων.) A rule or canon, by which medicines are compounded.

Cano′niai. (Κανονιαι.) Hippocrates in his book De Aëre, &c. calls those persons thus, who have straight, and not prominent bellies. He would intimate that they are disposed, as it were, by a straight rule.

Cano′picon. (From *κανωπον*, the flower of the elder.) A sort of spurge named from its resemblance; also a collyrium, of which the chief ingredient was elder flowers.

Canopi′te. The name of a collyrium mentioned by Celsus.

Cano′pum. (Κανωπον.) The flower or bark of the elder-tree, in Paulus Ægineta.

Canta′brica. See *Convolvulus.*

Canta′brum. (From *kanta*, Heb.) In Cœlius Aurelianus it signifies bran or furfur.

Ca′ntacon. Garden saffron.

Ca′ntara. The plant which bears the St. Ignatius's bean.

Ca′nthari figuli′ni. Earthen cucurbits.

CA′NTHARIS. (*Cantharis*, pl. *cantharides*: from *κανθαρος*, a beetle, to whose tribe it belongs.) See *Lytta.*

Ca′nthum. Sugar-candy.

CA′NTHUS. (Κανθος, the iron binding of a cart-wheel. Dr. Turton, in his glossary, supposes from its etymology, that it originally signified the circular extremity of the eyelid.) The angle or corner of the eye, where the upper and under eyelids meet. That next the nose is termed the internal or greater canthus, and the other, the external or lesser canthus.

Ca′ntion. An epithet for sugar.

Cantuarie′nsis a′qua. Canterbury water is strongly impregnated with iron, sulphur, and carbonic acid gas; it is recommended in disorders of the stomach, in gouty complaints, jaundice, diseases of the skin and chlorosis.

CA′NULA. (Dim. of *canna*, a reed.) A small tube. The term is generally applied to a tube adapted to a sharp instrument, with which it is thrust into a cavity or tumour, containing a fluid; the perforation being made, the sharp instrument is withdrawn, and the canula left, in order that the fluid may pass through it.

Canusa. Crystal.

Caoutchou'c. See *Indian rubber.*

Capaiva bálsam. See *Copaïfera officinalis.*

Capeli'na. (From *capeline,* a woman's hat, or bandage, French.) A double-headed roller put round the head.

Cape'lla. A cupel or test.

Caper-bush. See *Capparis.*

Ca'petus. (Καπετος, per aphæresin, pro σκαπετος; from σκαπτω, to dig.) Hippocrates means by this word a foramen, which is impervious and needs the use of a chirurgical instrument to make an opening; as the anus of some new-born infants.

Ca'phora. (Arab.) Camphire.

Ca'phura ba'ros indo'rum. A name for camphire.

Ca'phuræ o'leum. An aromatic essential oil distilled from the root of the cinnamon-tree.

Capilla'res vermi'culi. See *Crinones* and *Dracunculus.*

CAPI'LLARY. (*capillaris:* from *capillus,* a little hair; so called from the resemblance to hair or fine thread.) The very small ramifications of the arteries, which terminate upon the external surface of the body, or on the surface of internal cavities, are called capillary.

Capilla'tio. (From *capillus,* a hair.) A capillary fracture of the cranium.

CAPI'LLUS. (Quasi *capitis pilus,* the hair of the head.) The hair. Small, cylindrical, transparent, insensible, and elastic filaments, which arise from the skin, and are fastened in it by means of small roots. The human hair is composed of a spongy, cellular texture, containing a coloured liquid, and a proper covering. Hair is divided into two kinds: *long,* which arises on the scalp, cheek, chin, breasts of men, the anterior parts of the arms and legs, the arm pits groins, and pelvis: and *short,* which is softer than the long, and is present over the whole body, except only the palm of the hand and sole of the foot. The hair originates in the adipose membrane from an oblong membranous bulb, which has vessels peculiar to it. The hair is distinguished by different names in certain parts; as, *capillus,* on the top of the head: *crinis,* on the back of the head; *circrinnus,* on the temples; *cilium,* on the eyelids; *supercilium,* on the eyebrows; *vibrissa,* in the nostrils; *barba,* on the chin; *pappus,* on the middle of the chin; *mystax,* on the upper lip; *pilus,* on the body.

Capi'llus ve'neris. See *Adianthum.*

Capi'llus ve'neris Canade'nsis. The Adianthum Canadense.

Capiple'nium. (From *caput,* the head, and *plenus,* full.) A catarrh. It is a barbarous word; but Baglivi uses it to signify that continual heaviness or disorder in the head, which the Greeks call *Carebaria,* *καρηβαρια.*

Capistra'tio. (From *capistrum,* a bridle; so called because the præpuce is restrained as it were with a bridle.) See *Phimosis.*

Capi'strum. (From *caput,* the head.) A bandage for the head is so called. In Vogel's Nosology it is the same as *Trismus.*

CA'PITAL. The head or upper part of an alembic.

Capita'lia. (From *caput,* the head.) *Cephalics:* medicines which relieve disorders of the head.

Capite'llum. The head or seed vessels, frequently applied to mosses, &c. Some say it signifies soapy water, others say it is a lixivium.

Capitilu'vium. (From *caput,* the head, and *lavo,* to wash.) A lotion or bath for the head.

Cápitis oblíquus inférior et májor. See *Obliquus inferior capitis.*

Cápitis par tértium Fallópii. See *Trachelo-mastoideus.*

Cápitis postícus. See *Rectus capitis posticus major.*

Cápitis réctus. See *Rectus capitis posticus minor.*

Capi'tulum. (Dim. of *caput,* the head.)

1. A small head or protuberance of a bone, received into the concavity of another bone.

2. An alembic.

Capi'vi. (Indian.) A tree of Brazil, which affords the drug called balsam of capivi. See *Copaïfera officinalis.*

Capnelæ'um. (From καπνος, smoke, and ελαιον, oil; so named from its smoky exhalations when exposed to heat.) In Galen's works, it is said to be a resin.

Ca'pnias. (From καπνος, a smoke.) A jasper of a smoky colour. Also, a kind of vine which bears white and part black grapes.

Capni'ston. (From καπνος, smoke.) A preparation made of spices and oil, by kindling the spices, and fumigating the oil.

Capni'tis. (From καπνος, smoke; so called from its smoky colour.) Tutty.

Capnoi'des. (From καπνος, fumitory, and ειδος, likeness.) A species of fumitory.

Ca'pnos. Καπνος. Fumitory; so called, says Blanchard, because its juice, if applied to the eyes, produces the same effect and sensations as smoke.

Ca'po mola'go. The Piper Indicum.

Ca'ppa. (*à capite,* from the head; so called from its supposed resemblance.) The herb monkshood.

CA'PPARIS. (From *cabar,* Arab. or ϖαρα τό καππανειν αραν, from its curing madness and melancholy.) The caper plant.

1. The name of a genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Monogynia.*

2. The pharmacopœial name of the caper plant.

Ca'pparis spino'sa. The systematic name of the caper plant. *Capparis; pedunculis* *solitariis unifloris, stipulis spinosis, foliis annuis, capsulis ovalibus* of Linnæus. The buds, or unexpanded flowers of this plant, are in common use as a pickle, which is said to possess antiscorbutic virtues. The bark of the root was formerly in high esteem as a deobstruent.

Capreola′ris. (From *capreolus,* a tendril.) *Capreolatus.* Resembling in its contortions, or other appearance, the tendrils of a vine; as the spermatic vessels.

Capreola′tus. See *Capreolaris.*

Capre′olus. (Dim. of *caprea,* a tendril.) It means the helix or circle of the ear, from its tendril-like contortion. Dr. Turton suggests its derivation from *caper,* a goat, whose horn its contortions somewhat resemble.

Caprico′rnus. Lead.

Caprifi′cus. (From *caper,* a goat, and *ficus,* a fig; because they are a chief food of goats.) The wild fig-tree.

Capri′zans. Is by Galen and others used to express an inequality in the pulse, when it leaps, and, as it were, dances in uncertain strokes and periods.

Capse′lla. (Dim. of *capsa,* a chest, from its resemblance.) A name in Marcellus Empiricus for viper's bugloss.

CA′PSICUM. (From καπτω, to bite, on account of its effect on the mouth.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.* Guinea pepper.

2. The pharmacopœial name of the capsicum.

Ca′psicum annuum. The systematic name of the plant from which we obtain Cayenne pepper. *Piper Indicum. Lada chilli. Capo molago. Solanum urens. Siliquastrum Plinii. Piper Brazilianum. Piper Guineense. Piper Calecuticum. Piper Hispanicum. Piper Lusitanicum.* Cayenne pepper. Guinea pepper. This species of pepper is obtained from the *Capsicum; caule herbaceo, pedunculis solitariis* of Linnæus. What is generally used under the name of Cayenne pepper, however, is an indiscriminate mixture of the powder of the dried pods of many species of capsicum, but especially of the capsicum minimum, or bird pepper, which is the hottest of all. These peppers have been chiefly used as condiments. They prevent flatulence from vegetable food, and give warmth to the stomach, possessing all the virtues of the oriental spices, without producing those complaints of the head which the latter are apt to occasion. An abuse of them, however, gives rise to visceral obstructions, especially of the liver. In the practice of medicine, there can be little doubt that they furnish us with one of the purest and strongest stimulants which can be introduced into the stomach, and may be very useful in some paralytic and gouty cases. Dr. Adair, who first introduced them into practice, found them useful in the cachexia Africana, which he considers as a most frequent and fatal predisposition to disease among the slaves. Dr. Wright says, that in dropsical and other complaints where chalybeates are indicated, a minute portion of powdered capsicum forms an excellent addition, and recommends its use in lethargic affections. This pepper has also been successfully employed in a species of cynanche maligna, which proved very fatal in the West-Indies, resisting the use of Peruvian bark, wine, and other remedies commonly employed. In tropical fevers, coma and delirium are common attendants; and in such cases, cataplasms of capsicum have a speedy and happy effect. They redden the parts, but seldom blister unless when kept on too long. In ophthalmia from relaxation, the diluted juice of capsicum is found to be a valuable remedy. Dr. Adair gave six or eight grains for a dose, made into pills; or else he prepared a tincture by digesting half an ounce of the pepper in a pound of alkohol, the dose of which was one or two drachms, diluted with a sufficient quantity of water. A *tinctura capsici* is now for the first time introduced into the London pharmacopœia.

CA′PSULA. (Dim. of *capsa,* a chest or case.) A term given by anatomists to any membranous production enclosing a part of the body like a bag; as the capsular ligaments, the capsule of the crystalline lens, &c.

Ca′psulæ atrabila′riæ. See *Renal Glands.*

Ca′psulæ rena′les. See *Renal Glands.*

CA′PSULAR LI′GAMENT. (*Capsularis;* from *capsa,* a bag.) *Ligamentum capsulare.* The ligament which surrounds every moveable articulation, and contains the synovia like a bag.

CA′PSULE OF GLI′SSON. (*Capsula communis Glissonii. Vagina portæ. Vagina Glissonii.*) A strong tunic, formed of cellular texture, which accompanies the vena portæ, and its most minute ramifications, throughout the whole liver.

Ca′pulum. (From καμπτω, to bend.) A contortion of the eye-lids, or other parts.

Ca′pur. (Arab.) Camphor.

CA′PUT. (*capitis,* neut. from *capio,* to take; because from it, according to Varro, the senses take their origin.) The head, cranium, or skull. It is situated above or upon the trunk, and united to the cervical vertebræ.

It is distinguished into skull and face. On the skull are observed *vertex,* or crown; *sinciput,* or fore part; *occiput,* or hinder part; and the *temples.* The parts distinguished on the face are well known; as the forehead, nose, eyes, &c. The arteries of the head are branches of the carotids; and the veins empty themselves into the jugulars. See *Skull* and *Face.*

CA′PUT GALLINA′GINIS. *Verumontanum.* A cutaneous eminence in the urethra of men, before the neck of the bladder, somewhat like the head of a woodcock in miniature, around which the seminal ducts, and the ducts of the prostate gland, open.

Ca′put mo′rtuum. A fanciful term, much used by the old chemists, but now entirely rejected. It denoted the fixed residue of operations. As the earlier chemists did not examine these, they did not find any inconvenience in one general term to denote them: but the most slender acquaintance with modern chemistry must show, that it is utterly impracticable to denote, by one general term, all the various matters that remain fixed in certain degrees of heat.

CA′PUT OBSTI′PUM. The wry neck. Mostly a spasmodic complaint.

Ca′put pu′rgia. (A barbarous word, from *caput*, the head, and *purgo*, to purge.) Medicines which purge the head. Errhines. Masticatories.

Capyri′dion. (From *καπυρος*, burnt.) *Capyrion*. A medicated cake, much baked.

Capy′rion. See *Capyridion*.

Ca′rabe. (Persian.) Amber.

Ca′rabe fu′nerum. A name given to bitumen.

CA′RABUS. A genus of insects of the beetle kind. Two species, the chrysocephalus and ferrugineus, have been recommended for the tooth-ache. They must be pressed between the fingers, and then rubbed on the gum and tooth affected.

Caraco′smos. A name of the sour mare's milk, so much admired by the Tartars.

Caragua′ta. The common aloe of Brazil.

Cara′nna. (Spanish.) *Caragna*. *Carannæ gummi*. *Bresilis*. A concrete resinous juice, that exudes from a large tree, of which we have no particular account. It is brought from New Spain and America, in little masses, rolled up in leaves of flags; externally and internally it is of a brownish colour, variegated with irregular white streaks. When fresh, it is soft and tenacious; but becomes dry and friable by keeping. Pure caranna has an agreeable aromatic smell, especially when heated, and a bitterish slightly pungent taste. It was formerly employed as an ingredient in vulnerary balsams, strengthening, discutient, and suppurating plasters; but its scarcity has caused it to be forgotten.

Ca′ra schu′lli. (Indian.) *Frutex Indica spinosa*. An Indian shrub, like the caper-bush. A decoction of the root proves diuretic. *Ray*.

Caraway-seed. See *Carum*.

Ca′rbasus. (Καρϐασος.) Scribonius Largus uses this word for lint.

CA′RBO. (*Charbah*, Heb. burnt or dried.) Coal. In medicine and chemistry, it is commonly understood to mean charcoal, and receives its name from its mode of preparation, which is by burning pieces of light wood into a dry black coal.

Ca′rbo li′gni. Charcoal. As an external application, powdered charcoal has been recommended in the cure of gangrene, from external causes, and all descriptions of fœtid ulcers. Meat which has acquired a mawkish or even putrid smell, is found to be rendered perfectly sweet, by rubbing it with powdered charcoal. It is also used as tooth-powder.

CA′RBON. (From *carbo*, coal.) The chemical name of charcoal. It is the black residue of vegetables which have suffered a complete decomposition of their volatile principles by fire. Charcoal is black, brittle, sonorous, and light. It is placed among simple bodies, because no experiment has hitherto shown the possibility of decomposing it. It exists in the animal, vegetable, and mineral kingdom. When it is required to procure carbon in a state of great purity, it must be dried by strong ignition in a closed vessel. The diamond, when burnt in oxygen gas, forms carbonic acid, like charcoal, and is therefore considered to be of the same chemical nature.

CA′RBON, GA′SEOUS O′XIDE OF. Gaseous oxide of carbon was first described by Dr. Priestley, who mistook it for a hydro-carbonate. With the true nature of it, we have been only lately acquainted. It was first proved to be a peculiar gas, by Mr. Cruikshank, of Woolwich, who made it known to us as such, in April, 1801, through the medium of Nicholson's Journal for that month. Several additional properties of this gas were soon afterwards noticed by Desormes, Clement, and others. Gaseous oxide of carbon forms an intermediate substance between the pure hydro-carbonates and carbonic acid gas; but not being possessed of acid properties, Mr. Cruikshank has called it, conformably to the rules of the chemical nomenclature, *gaseous oxide of carbon*, for it consists of oxigen and carbon rendered gaseous by caloric.

Though the gaseous oxide of carbon has some of the properties peculiar to the common hydro-carbonates, the following characteristic properties sufficiently prove that none of those at present known are similar to it. We are, therefore, entitled to consider it as a peculiar gas.

Properties. — Gaseous oxide of carbon is lighter than common air, in the proportion of 22 to 23. When mingled with common air, and ignited, it does not explode, but burns with a lambent blue flame, and the product is carbonic acid. It is very little absorbable by water: it is void of taste and odour. A mixture of 20 parts of gaseous oxide of carbon and 8 of oxigen gas, fired over mercury by electricity, diminishes to a volume equal to about 18 or 19 parts, which is carbonic acid gas. It contains neither water nor the basis of that fluid. It is exceedingly noxious; animals die in it instantly; when breathed for a few minutes only, it produces giddiness and faintings.

Neither light, heat, nor electricity, have any effect upon it. When equal quantities of gaseous oxide of carbon and hydrogen gas are passed through a red-hot glass tube, the tube is lined with charcoal, water is formed, and an excess of hydrogen makes its escape. If a piece of iron be put into the tube, it is oxidated, but not converted into steel. Neither nitrogen gas nor sulphur have any action on it even at high temperatures. It is capable of dissolving a minute quantity of charcoal, and increases in bulk. It dissolves phosphorus, and acquires the property of burning with a yellow flame. The alkalies have no effect on this gas. It is not altered when passed with ammonia through an ignited tube. When the red oxide of mercury is heated in it, a commencement of reduction takes place. Neither sulphuric, nitric, nor nitro-muriatic acids, alter it, when passed with it through a red-hot tube. Four parts of oxigenated muriatic acid gas left with one of gaseous oxide of carbon, decompose it completely. Nitrous gas has no effect upon it. When mixed with sulphuretted hydrogen gas, and passed through a red-hot tube, sulphur is deposited, and sulphuretted hydrogen gas remains mixed with gaseous oxide of carbon.

Methods of obtaining Gaseous Oxide of Carbon.— Gaseous oxide of carbon may be obtained by a decomposition of carbonic acid at high temperatures, by means of various fixed substances which have a considerable affinity to oxigen. This may be done by exposing to a strong red heat, a mixture of carbonate of lime or barytes, and filings of iron, zinc, &c. It may also be procured by distilling a mixture of charcoal with some of the metallic oxides.

The method of obtaining the gaseous oxide of carbon in a state of purity, recommended by Mr. Cruikshank, is the following:

1. Take one part of chalk, previously exposed to a low red heat, for about ten minutes, mix it with an equal quantity of perfectly dry filings of zinc; let the mixture be introduced into a retort, and expose it to a heat gradually increased. As soon as the retort becomes of a dull red heat, gas will be disengaged in great abundance. The gas which comes over first is carbonic acid gas, but as soon as the retort becomes thoroughly ignited, pure gaseous oxide of carbon is liberated in a prodigious quantity, which may be collected in the usual manner over water.

In this process, a decomposition of the carbonic acid of the chalk takes place in its nascent state. The zinc robs the carbonic acid of part of its oxigen at a high temperature, and becomes to a certain degree oxidated. The carbonic acid, by being thus deprived of part of its oxigen, becomes converted into a new inflammable gas, which is the gaseous oxide of carbon.

Carbonaceous acid. See *Carbonic acid.*

CARBO'NAS. A carbonate. A neutral salt, formed by the union of carbonic acid with an alkaline, earthy, or metallic base. The carbonates employed in medicine are:

1. The potassæ carbonas.
2. The sodæ carbonas.
3. The creta præparata, and the testæ præparatæ, which are varieties of carbonate of lime.

When the base is imperfectly neutralized by the carbonic acid, the salt is termed a subcarbonate; of which kind are employed medicinally:

1. The potassæ subcarbonas.
2. The sodæ subcarbonas, and the sodæ subcarbonas exsiccata.
3. The ammoniæ subcarbonas, and the liquor ammoniæ subcarbonatis.
4. The plumbi subcarbonas.
5. The ferri subcarbonas.
6. The magnesiæ carbonas.

Carbo'nas ammo'niæ. See *Ammoniæ subcarbonas.*

CARBO'NAS CA'LCIS. Carbonate of lime. Several varieties of this are used in medicine: the purest and best are the creta præparata, testæ preparatæ, chelæ cancrorum, testæ ovorum, and oculi cancrorum.

Carbo'nas fe'rri. See *Ferri subcarbonas.*

Carbo'nas magne'siæ. See *Magnesiæ carbonas.*

Carbo'nas plumbi. See *Plumbi subcarbonas.*

Carbo'nas pota'ssæ. See *Potassæ carbonas.*

Carbo'nas so'dæ. See *Sodæ carbonas.*

Carbonated hydrogen gas. See *Carburetted hydrogen gas.*

CA'RBONIC ACID GAS. *Acidum Carbonicum.* Fixed air. Carbonaceous acid. Calcareous acid. Aërial acid. Carbonic acid gas is the first elastic aëriform fluid that was known after common air. We find that the antients were in some measure acquainted with it. Van Helmont called it the gas of Must, or of the vintage, or *gas sylvestre.*

We are indebted to Dr. Black of Edinburgh for the knowledge of some of the most remarkable properties of this fluid. In the year 1755 he discovered the affinity between this gas and alkalies: and Bergman, in 1772, proved that it was an acid.

Properties. — Carbonic acid gas is invisible. It extinguishes flame. It is fatal to animal life. It exerts powerful effects on living vegetables. Its taste is pungent and acid. Its energy, as an acid, is but feeble, although distinct and certain. Neither light or caloric seem to produce any distinct effect upon it, except that the latter dilates it. It unites with water slowly. These two fluids, after considerable agitation, at last combine, and form a sub-acid liquid. The colder the water, and the greater the pressure applied, the more carbonic acid gas will be absorbed. The water impregnated with it, sparkles upon agitation; it has a pungent, acidulous taste, and reddens tincture of litmus. Heat again disengages the gas from the water. This gas precipitates lime, strontia, and barytes, from their solutions in water. It is greedily attracted by all the alkalies. Its specific weight is to that of atmospheric air, as 1500 to 1000 nearly. It may be poured out of one vessel into another. It is not acted upon by oxygen, nor is it altered by any of the simple combustible bodies at common temperatures; but charcoal, iron, and some other metals are capable of decomposing it when assisted by heat; as is also phosphorus, when united to lime.

Methods of obtaining Carbonic Acid Gas.

Of all the gases, carbonic acid gas is that, perhaps, which is diffused in the greatest abundance throughout nature. It is found in three different states: — 1st, In that of gas; 2dly, In that of mixture; and 3dly, In that of combination. The various processes for obtaining it are the following.

1. Put into a common glass-bottle, or retort, a little marble, chalk, or lime-stone, and pour on it sulphuric acid, diluted with about six times its weight of water, an effervescence will ensue, and carbonic acid gas will be liberated, which those who have an opportunity may collect over mercury; but a mercurial apparatus is not absolutely necessary, since the gas may be collected over water, if it is to be used immediately when procured.

In this instance the carbonic acid is disengaged from the state of combination, and reduced to the aëriform state. The marble, lime-stone, or chalk, consists of this acid and lime; on presenting to it sulphuric acid, a decomposition takes place, the sulphuric acid has a greater affinity to the lime than the carbonic acid gas; it therefore unites to it, and forms sulphate of lime, disengaging at the same time the carbonic acid in the state of gas, at the temperature of our atmosphere.

Remark. — Carbonic acid gas may, in this manner, be disengaged from all its combinations with alkalies; by using indifferently any other dense acid, possessing a superior affinity to the alkali in the common acceptation of the word.

2. It may likewise be obtained from the same substances by the action of caloric.

For this purpose, reduce marble, or chalk, to powder; introduce it into a gun-barrel, which must be placed across a furnace; adapt a bent tube to the end of the gun-barrel, and insert it below a receiver in the pneumatic apparatus. Maintain a strong heat, till the barrel is brought to a state of ignition, and at that temperature carbonic acid gas will be liberated in abundance.

In this case, a decomposition of the marble or carbonate of lime takes place, on account of the action of caloric, which at a high temperature breaks the affinity of the carbonic acid and lime; it unites with the first, and leaves the lime behind in that state which is generally called quick-lime.

3. Carbonic acid gas may also be obtained by burning charcoal in oxygen gas.

Take a bell-glass, filled with oxygen gas, resting inverted in a bason of mercury; pass up into it some bits of new-made charcoal, with some touch-paper affixed to them; set fire to them by means of a lens collecting the sun's rays, and carbonic acid will be produced by the combustion of the charcoal.

Carbonic acid gas is often found occupying the lower parts of mines, caverns, tombs, and such other subterraneous places as contain materials for producing it. It is called choke, or chalk-damp. The grotto del Cane, near Naples, has long been famous for the quantity of carbonic acid gas produced there, which runs out at the opening like a stream of water. The quantity of carbonic acid gas generated in this cavern, is so great, that a dog, or any other animal, is immediately killed if his nose be thrust into it.

The carbonic acid, existing naturally in the state of gas, may be collected by filling bottles with water and emptying them into the atmosphere of this gas; the gas takes the place of the water, and fills the bottles, which must then be corked.

Carbonic acid gas is likewise formed during fermentation; on account of its great weight, it occupies the apparently empty space, or upper part of the vessel in which the fermenting process is going on. It may, in this case, be collected in a manner similar to that above.

Carbonic acid gas is also obtained during the reduction of metallic oxides, and during the deflagration of nitrates, with combustible bodies. This gas is much esteemed in the cure of typhus fevers, and of irritability and weakness of stomach producing vomiting. Against the former diseases it is given by administering yeast, bottled porter, and the like; and for the latter it is disengaged from the carbonated alkali by lemon juice in a draught given while effervescing.

Carbuncle. See *Anthrax.*

CARBU'NCULUS. (Dim. of *carbo,* a burning coal.) A carbuncle. *Carbo. Rubinus verus. Codesella. Erythema gangrænosum. Granatristum. Pruna. Persicus ignis* of Avicenna. An inflammatory tumour which soon becomes gangrenous. See *Anthrax.*

CARBURETTED HYDROGEN GAS. *Carbonated Hydrogen gas. Heavy inflammable Air. Hydro-carbonate.* There are two gaseous compounds of carbon and

or
ai
the

hydrogen in definite proportions, differing materially in specific gravity and other circumstances.

I. Light carburetted hydrogen gas has a fetid odour. It is neither absorbed nor altered by water. It is inflammable, and burns with a denser and deeper coloured flame than hydrogen gas. It is unalterable by acids or alkalies. Its specific gravity is greater than that of hydrogen gas. Its combustion with a due proportion of oxygen gas, is productive of water and carbonic acid. When passed through melted sulphur, it becomes converted into sulphuretted hydrogen gas, and charcoal is deposited. Electrization dilates it permanently to a little more than twice its original bulk: but when dried the dilatation is much less. The air thus expanded, requires a greater quantity of oxygen to decompose it, than the same quantity of gas not dilated by electricity; 100 cubic inches of pure light carburetted hydrogen gas weigh about seventeen grains.

Light carburetted hydrogen gas may be obtained from animal, vegetable, or mineral substances. Nature produces it ready formed in marshes and ditches, on the surface of putrid water, in mines, burying-places, common sewers, and in those situations where putrid animal and vegetable matters are accumulated. It is also generated in the intestinal canal of living animals.

1. Light carburetted hydrogen gas may be plentifully procured from most stagnant waters: to do this, fill a wide-mouthed bottle with the water, and keep it inverted therein with a funnel in its neck; then, with a stick, stir the mud at the bottom, just under the funnel in the bottle, so as to let the bubbles of air, which rise from the mud, enter into the bottle; when by thus stirring the mud in various places, and catching the air in the bottle, it is filled, it must be corked under water.

2. It may be also obtained during the distillation of animal and vegetable matter. For instance:

Let shavings of wood or saw-dust be put into a retort, and begin the distillation with a gentle heat, increasing it gradually till the retort becomes red hot; a great quantity of gas will be liberated, which may be caught over water. On examining this gas, it will be found to consist of carbonic acid gas and carburetted hydrogen gas. In order to obtain the latter in a state of purity, the whole must be shaken with lime-water, or with a caustic alkaline solution. The carbonic acid gas will be absorbed, and the carburetted hydrogen gas left behind in a pure tsate.

The production of the gas in this manner, is the result of a partial analysis of the wood. It proves that wood contains solid hydrogen, carbon and oxygen. When the intensity of the heat has reached a certain degree, a part of the charcoal unites with part of the oxygen, and produces carbonic acid, which, by means of caloric, is melted into the gaseous state, and forms carbonic acid gas; at the same time, a part of the hydrogen of the wood combines with another portion of carbon and caloric, and forms carburetted hydrogen gas.

Remark. — The flame of burning wood, &c. is the inflamed carburetted hydrogen gas, liberated on the application of caloric to such bodies.

3. Charcoal has been in general made use of for obtaining light carburetted hydrogen gas. For this purpose, put some moistened charcoal into an earthen retort, apply heat, and increase it till the retort becomes ignited; gas will be evolved, consisting partly of carbonic acid gas, and partly of light carburetted hydrogen gas, which may be separated as before.

In this case a decomposition of the water takes place, by means of the charcoal. The oxygen forsakes its hydrogen, and unites to part of the charcoal, at this temperature, and forms carbonic acid gas, in conjunction with caloric; the liberated hydrogen assisted by caloric, dissolves another portion of the charcoal, and forms with it light carburetted hydrogen gas: but some carbonic oxide is mixed with it.

4. Light carburetted hydrogen gas is also obtained abundantly from the distillation of pit-coal; and now very extensively used as a substitute for oil in lighting the streets of this metropolis, &c.

II. Heavy carburetted hydrogen gas was first brought into notice by a society of Dutch chemists, consisting of Deiman, Troostwyk, Bond, and Laurenburgh. They observed in this gas the particular property, that when it was combined with oxygenated muriatic acid gas, in a certain proportion, the elastic form of both fluids became destroyed, and an oil was produced; for which reason they called it *Olefiant gas.*

Properties. — Heavy carburetted hydrogen gas is not absorbed or altered by water. Its weight nearly equals that of common air. It has a disagreeable fetid odour, different from that of light carburetted hydrogen gas. It burns with a strong compact flame, similar to that of resinous oil. When mixed with oxygenated muriatic acid gas, its bulk is diminished, and an oil is formed. When the mixture of these two gases is fired, a quantity of charcoal is immediately deposited, in the form of fine soot. Sulphuric, sulphurous, nitric, and muriatic acids do not act upon it; neither does nitrous gas, nor any of the fixed alkalies. Ammonia adds to its volume without occasioning any other change. Phosphorus heated in it even to fusion, does not affect it. When made to pass through an ignited glass tube, it does not diminish in volume, but loses the property of forming oil with oxygenated muriatic acid gas. Electric shocks passed through it, dilate, and likewise deprive it of this property. When passed through a tube with sulphur in fusion, sulphuretted hydrogen gas is obtained, and charcoal deposited. When burnt with oxygen gas, or when passed through a red-hot tube, filled with oxide of manganese, carbonic acid gas is formed, as well as water.

Preparation. — Heavy carburetted hydrogen gas is obtained by decomposing alkohol by sulphuric acid, at high temperatures. It is also obtained in abundance when alkohol or ether is passed through a red-hot earthen tube. Sulphuric ether mixed with sulphuric acid, and subjected to heat, also affords it, but in a less pure state.

The Dutch chemists observed, that if the vapour of ardent spirit or ether be made to pass through a glass tube, over the component parts of the earthen tube, namely, alumine and silex, this gas was also produced; or by passing it through a red-hot tube of pipe-clay.

In order to obtain this gas the following method may serve:

Let four parts of concentrated sulphuric acid, and one of highly rectified ardent spirit, be mingled together gradually in a glass retort; heat will be developed, the mixture will become brown, and heavy carburetted hydrogen gas will be extricated without the application of external heat. When a moderate heat is applied, the action is very violent, and the gas is liberated very copiously, and may be received over water.

The gas obtained, is always mixed with a considerable quantity of sulphurous acid gas, from which it may be freed by agitating it in contact with lime-water, or a solution of potash.

Remark. — In this operation, the heat ought to be regulated with great care, and the retort holding the mixture ought to be very capacious, otherwise the matter will be forced over into the receiver. The heat of a candle, or lamp, is sufficient.

Ca′rcarus. *Carcaros.* (From καρκαιρω, to resound.) A kind of fever in which the patient has a continual horror and trembling, with an unceasing sounding in his ears.

Ca′rcas. The Barbadoes nut-tree, the Cataputia.

Ca′rcax. (From καρα, a head.) A species of poppy, with a very large head.

Ca′rcer. Paracelsus means by it, a remedy proper for restraining the disorder by motions of body and mind, as in curing the *chorea Sancti Viti.*

Carche′sius. (Καρχησιος.) A name of some bandages noticed by Galen, and described by Oribasius. Properly it is the top of a ship's mast.

CARCINO′MA. (From καρκινος, a cancer.) See *Cancer.*

Carcinos. (Καρκινος, a cancer.) See *Cancer.*

Cardama′ntica. (From καρδαμον, the nasturtium.) A species of sciatica cresses.

Cardamele′um. A medicine of no note, mentioned by Galen.

CARDAMI′NE. (From καρδια, the heart; because it acts as a cordial and strengthener, or from its having the taste of cardamum, that is, nasturtium, or cress.) Cuckoo-flower.

1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia.* Order, *Siliquosa.*

2. The pharmacopœial name of the common lady's smock, or cuckoo-flower. See *Cardamine pratensis.*

Cardami′ne prate′nsis. The systematic name of the plant called *cardamine* in the pharmacopœias. *Cardamine; foliis pinnatis; foliolis, radicalibus subrotundis, caulinis lanceolatis* of Linnæus. This plant is also called *Cardamantica. Nasturtium aquaticum. Culi flos. Iberis sophia.* It is the flower of this plant which has a place in the materia medica, upon the authority of Sir George Baker, who has published five cases, two of chorea Sancti Viti, one of spasmodic asthma, one of hemiplegia, and a case of spasmodic affections of the lower limbs, wherein the *flores cardamines* were supposed to have been successfully used. A variety of virtues have been given to this plant, which do not deserve the attention of practitioners.

Cardami′nes flo′res. See *Cardamine pratensis.*

CARDAMO′MUM. (From καρδαμον, and αμωμον: because it partakes of the nature, and is like both the cardamum and amomum.) The cardamom seed.

CARDAMO′MUM MA′JUS. The greater cardamom seeds, by some called grains of Paradise, are contained in a large, brown, somewhat triangular husk, the thickness of one's thumb, and pyramidal; their virtues are similar to those of the *cardamomum minus.*

CARDAMO′MUM ME′DIUM. The seeds correspond, in every respect, with the lesser, except in size, they being twice as long, but no thicker than the *cardamomum minus.*

Cardamo′mum mi′nus. See *Elettaria Cardamomum.*

Cardamo′mum pipera′tum. The grains of Paradise.

Cardamo′mum Siberie′nse. The Anisum Indicum.

Ca′rdamum. (From καρδια, the heart; because it comforts and strengthens the heart.) Garden cresses.

CA′RDIA. (From κεαρ, the heart.) This term was applied by the Greeks to the heart. The superior opening of the stomach is also so called.

CARDI′ACA. (From καρδια, the heart.)

1. Cordials. See *Cordials.*

2. The pharmacopœial name of motherwort. (So named from the supposed relief

it gives in faintings and disorders of the stomach. See *Leonurus cardiaca.*

Cardi'aca confe'ctio. See *Confectio aromatica.*

Cardi'aca pa'ssio. The cardiac passion. Antient writers frequently mention a disorder under this name, but the moderns always speak of it as a syncope.

Cabdi'acus mo'rbus. A name by which the antients called the typhus fever.

CARDIA'LGIA. (From καρδια, the cardia, and αλγος, pain.) Pain at the stomach. The heartburn. Dr. Cullen ranks it as a symptom of dyspepsia. Heartburn is an uneasy sensation in the stomach, with anxiety, a heat more or less violent, and sometimes attended with oppression, faintness, an inclination to vomit, or a plentiful discharge of clear lymph, like saliva. This pain may arise from various and different causes; such as *flatus;* from *sharp humours,* either acid, bilious, or rancid; from *worms* gnawing and vellicating the coats of the stomach; from *acrid* and *pungent food,* such as spices, aromatics, &c.; as also from *rheumatic* and *gouty humours,* or *surfeits;* from too free a use of tea, or watery fluids relaxing the stomach, &c.; *from the natural mucus* being abraded, particularly in the upper orifice of the stomach.

Cardia'lgia inflammato'ria. Inflammation in the stomach.

Cardia'lgia sputato'ria. See *Pyrosis.*

Cardime'lech. (From καρδια, the heart, and *meleck,* Heb. a governor.) A fictitious term in Dolæus's Encyclopædia, by which he would express a particular active principle in the heart, appointed to what we call the vital functions.

Cardimo'na. A name for Cardialgia.

Cardinal flowers, blue. See *Lobelia.*

Cardiname'ntum. (From *cardo,* a hinge.) A sort of articulation like a hinge.

CARDIO'GMUS. (From καρδιωσσω, to have a pain in the stomach.) The same as *Cardialgia.* Also an aneurism in the aorta, near the heart, which occasions pain in the præcordia.

Cardio'nchus. (From καρδια, the heart, and ογκος, a tumour.) An aneurism in the heart, or in the aorta near the heart.

Cardiotro'tus. (From καρδια, the heart.) and τιτρωσκω, to wound.) One who hath a wound in his heart.

CARDI'TIS. (From καρδια, the heart.) Inflammation of the heart. It is a genus of disease arranged by Cullen in the class *pyrexiæ,* and order *phlegmasiæ.* It is known by pyrexia, pain in the region of the heart, great anxiety, difficulty of breathing, cough, irregular pulse, palpitation, and fainting, and the other symptoms of inflammation.

The treatment of carditis is, in a great measure, similar to that of pneumonia. It is necessary to take blood freely, as well generally as locally, and apply a blister near the part. Purging may be carried to a greater extent than in pneumonia; and the use of digitalis is more important, to lessen the irritability of the heart. It is equally desirable to promote diaphoresis, but expectoration is not so much to be looked for, unless indeed, as very often happens, the inflammation should have extended, in some degree, to the lungs.

Ca'rdo. (A hinge.) The articulation called *Ginglymus;* also the second vertebra of the neck.

Ca'rdonet. A wild artichoke, esculent.

Cardo'nium. So Paracelsus calls wine medicated with herbs.

Cardopa'tium. The low carline thistle, said to be diaphoretic.

CA'RDUUS. (*à carere, quasi aptus carendæ lanæ,* being fit to tease wool; or from κειρω, to abrade; so named from its roughness, which abrades and tears whatever it meets with.) The thistle, or teasel. The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia æqualis.*

Ca'rduus aca'nthus. The bear's breech.

Ca'rduus a'ltilis. The artichoke.

Ca'rduus benedi'ctus. See *Centaurea.*

Ca'rduus hæmorrhoida'lis. (So called because it is said to relieve the pains of the hæmorrhoids, if beat into a poultice and applied.) Also called carduus vinearum repens, sonchi folio. Cirsium arvense. Ceanothos. The common creeping way thistle. *Serratula arvensis* of Linnæus.

Ca'rduus la'cteus. See *Carduus Marianus.*

Ca'rduus la'cteus Syri'acus. The Spanish milk-thistle. Stomachic and anodyne.

Ca'rduus mariæ. See *Carduus marianus.*

Ca'rduus maria'nus. The systematic name of the officinal *Carduus Mariæ.* Carduus albis maculis notatus vulgaris, C. B. Common milk-thistle, or Lady's thistle. The seeds of this plant, *Carduus marianus: foliis amplexicaulibus, hastato-pinnatifidis, spinosis; calycibus aphyllis; spinis caniliculatis, duplicato-spinosis,* of Linnæus, and the herb have been employed medicinally. The former contain a bitter oil, and are recommended as relaxants. The juice of the latter is said to be salutary in dropsies, in the dose of four ounces; and, according to Miller, to be efficacious against pungent pains.

Ca'rduus sati'vus. The artichoke.

Ca'rduus solstitia'lis. The calcitrapa officinalis.

Ca'rduus tomento'sus. The woolly thistle. See *Onopordium acanthium.*

Careba'ria. (From καρη, the head, and βαρος, weight.) A painful and uneasy heaviness of the head.

Care'num. (From καρη, the head.) Galen uses this word for the head.

Care'num vi'num. Strong wine.

Ca'reum. (From *Caria,* the country whence they were brought.) The caraway.

CA'REX. (*Carex, -icis,* fœm. from *careo,* not *quia viribus careat,* but because, from its roughness, it is fit *ad carendum,* to card, tease, or pull.) Sedge. The name of a genus of plants in the Linnæan system. Class, *Monoecia.* Order, *Triandria.*

Ca'rex arena'ria. The systematic name of the officinal *sarsaparilla Germanica,* which grows plentifully on the sea coast. The root has been found serviceable in some mucal affections of the trachea, in rheumatic pains, and gouty affections.

CA'RICA. (From *Caria,* the place where they were cultivated.) The fig. See *Ficus carica.*

Ca'rica papa'ya. Papaw-tree. This is a native of both Indies, and the Guinea coast of Africa. When the roundish fruit are nearly ripe, the inhabitants of India boil and eat them with their meat, as we do turnips. They have somewhat the flavour of a pompion. Previous to boiling, they soak them for some time in salt and water, to extract the corrosive juice, unless the meat they are to be boiled with should be very salt and old, and then this juice being in them, will make them as tender as a chicken. But they mostly pickle the long fruit, and thus they make no bad succedaneum for mango. The buds of the female flowers are gathered, and made into a sweetmeat; and the inhabitants are such good husbands of the produce of this tree, that they boil the shells of the ripe fruit into a repast, and the insides are eaten with sugar in the manner of melons. Every part of the papaw tree, except the ripe fruit, affords a milky juice, which is used, in the Isle of France, as an effectual remedy for the tape-worm. In Europe, however, whither it has been sent in the concrete state, it has not answered, perhaps from some change it had undergone, or not having been given in a sufficient dose.

Ca'ricum. (From *Caricus,* its inventor.) *Carycum.* An ointment for cleansing ulcers, composed of hellebore, lead, and cantharides.

CA'RIES. (From *carah,* Chald.) Rottenness, or mortification of the bones.

Cari'ma. The cassada bread.

Cari'na. A name formerly applied to the back-bone.

Ca'rium te'rra. Lime.

Carivilla'ndi. A name of sarsaparilla root.

CARLI'NA. (From *Carolus,* Charles the Great, or Charlemagne; because it was believed that an angel showed it to him, and that, by the use of it, his army was preserved from the plague.) Carline thistle. The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia æqualis.* The officinal name of two kinds of plants.

Carli'na acau'lis. The systematic name of the *chamæleon album.* *Carlina.* *Cardopatium.* Carline thistle. *Carlina acaulis; caule unifloro, flore breviore* of Linnæus. The root of this plant is bitter, and said to possess diaphoretic and anthelmintic virtues. It is also extolled by foreign physicians in the cure of acute, malignant, and chronic disorders.

Carli'na gummi'fera. *Carduus pinea.* *Ixine.* Pine thistle. This plant is the *Atractylis gummifera* of Linnæus. The root, when wounded, yields a milky, viscous juice, which concretes into tenacious masses, at first whitish, resembling wax, when much handled growing black; it is said to be chewed with the same views as mastich.

Carline thistle. See *Carlina acaulis.*

Ca'rlo Sa'ncto ra'dix. St. Charles's root; so called by the Spaniards, on account of its great virtues. It is found in Mechoachan, a province in America. Its bark hath an aromatic flavour, with a bitter acrid taste. The root itself consists of slender fibres. The bark is sudorific, and strengthens the gums and stomach.

CA'RMEN. (*Carmen, -inis,* neut. A verse; because charms usually consisted of a verse.) A charm; an amulet.

Carmes. (The Carmelite friars, Fr.) Carmelite water; so named from its inventors; composed of baum, lemon-peel, &c.

Carmina'ntia. See *Carminatives.*

CARMI'NATIVES. (*Carminativa,* sc. *medicamenta:* from *carmen,* a verse or charm; because practitioners, in antient times, ascribed their operation to a charm or enchantment.) A term applied to those substances which allay pain, and dispel flatulencies of the primæ viæ. The principal carminatives are the semina cardamomi, anisi et carui; olea essentialia carui, anisi et juniperi; confectio aromatica; pulvis aromaticus; tinctura cardamomi; tinctura cinnamoni composita; zinziber; tonics, bitters, and astringents.

Carnaba'dium. Caraway-seed.

CA'RNEÆ COLU'MNÆ. The fleshy pillars or columns in the cavities of the heart. See *Heart.*

Carni'cula. (Dim. of *caro, carnis,* the flesh.) The fleshy substance which surrounds the gums.

Carnifo'rmis. (From *caro,* flesh, and *forma,* likeness.) Having the appearance of flesh. It is commonly applied to an abscess where the flesh surrounding the orifice is hardened, and of a firm consistence.

CA'RO. (*Caro, carnis,* fœm.) Flesh. The red part or belly of a muscle; also the pulp of fruit.

Ca'ro adna'ta. The recent swelled testicle.

Caroli'na. See *Carlina.*

Caro'pi. The amomum verum.

Caro'ra. The name of a vessel that resembles an urinal.

Caro'sis. See *Carus.*

Caro′ta. See *Daucus.*

Carotide′æ arte′riæ. See *Carotid artery.*

CAROTID ARTERY. (From καροω, to cause to sleep; so called because, if tied with a ligature, they cause the animals to be comatose, and have the appearance of being asleep.) The carotids are two considerable arteries that proceed, one on each side of the cervical vertebræ, to the head, to supply it with blood. The right carotid does not arise immediately from the arch of the aorta, but is given off from the arteria innominata. The left arises from the arch of the aorta. Each carotid is divided into external and internal, or that portion without and that within the cranium. The external gives off eight branches to the neck and face, viz. *anteriorly*, the superior thyroideal, the sublingual, the inferior maxillary, the external maxillary; *posteriorly*, the internal maxillary, the occipital, the external auditory, and the temporal. The internal carotid or cerebral artery, gives off four branches within the cavity of the cranium; the anterior cerebral, the posterior, the central artery of the optic nerve, and the internal orbital.

Caro′um. The caraway seed.

Ca′rpasus. (So named ϖαρα το καρον ϖοιησαι: because it makes the person who eats it appear as if he was asleep.) A herb, the juice of which was formerly called opocarpason, opocarpathon, or opocalpason; according to Galen it resembles myrrh; but is esteemed highly poisonous.

Carpa′thicum balsamum. See *Pinus Cembra.*

Carpenta′ria. (From *carpentarius*, a carpenter; and so named from its virtues in healing cuts and wounds made by a tool.) A vulnerary herb; but not properly known what it is.

Carpha′leus. (From καρφω, to exsiccate.) Hippocrates uses this word to mean *dry*, opposed to *moist.*

Carpholo′gia. (From καρφος, the nap of clothes, and λεγω, to pluck.) A delirious picking of the bed-clothes, a symptom occurring in dangerous fevers.

Ca′rphus. (From καρφη, a straw.) In Hippocrates it signifies a mote, or any small substance. A pustule of the smallest kind. Also the herb fenugreek.

Ca′rpia. (From *carpo*, to pluck, as lint is made from linen cloth.) Lint. See *Linteum.*

Carpi′smus. The wrist.

CARPOBA′LSAMUM. (From καρπος, fruit, and βαλσαμον, balsam.) See *Amyris Gileadensis.*

Carpolo′gia. See *Carphologia.*

CA′RPUS. (Καρπος, the wrist.) The wrist, or carpus. It is situated between the fore-arm and hand. See *Bone.*

Carrot. See *Daucus.*

Carrot, candy. See *Athamanta Cretensis.*

Carrot poultice. See *Cataplasma dauci.*

CA′RTHAMUS. (From καθαιρω, to purge.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia æqualis.*

2. The pharmacopœial name of the saffron flower. See *Carthamus tinctorius.*

Ca′rthamus tincto′rius. The systematic name of the saffron flower. *Carthamus; foliis ovatis, integris, serrato-aculeatis* of Linnæus: called also *Cnicus, Crocus Saracenicus, Carthamum officinarum, Carduus sativus.* The plant is cultivated in many places on account of its flowers, which are used as a yellow dye. The seeds, freed from their shells, have been celebrated as a gentle cathartic, in the dose of one or two drachms. They are also supposed to be diuretic and expectorant; particularly useful in humoral asthma, and similar complaints. The *carthamus lanatus* is considered in France as a febrifuge and sudorific. The dried flowers are frequently mixed with saffron, to adulterate it.

CARTHEUSER, John Frederick, a professor of medicine at Francfort on the Oder, acquired considerable reputation about the middle of the last century, by several luminous works on botany and pharmacy; especially his "Rudimenta Materiæ Medicæ Rationalis," and "De Genericis quibusdam Plantarum Principiis." He had two sons, Frederick Augustus and William, also of the medical profession, and authors of some less important works.

Carthusia′nus. (From the Monks of that order, who first invented it.) A name of the precipitated sulphur of antimony.

CA′RTILAGE. (*Cartilago, -inis.* fœm. Quasi *carnilago;* from *caro, carnis,* flesh.) A white elastic, glistening substance, growing to bones, and commonly called *gristle.* Cartilages are divided, by anatomists, into *obducent*, which cover the moveable articulations of bones; *inter-articular*, which are situated between the articulations, and *uniting* cartilages, which unite one bone with another. Their use is to facilitate the motions of bones, or to connect them together.

CARTILA′GO ANNULA′RIS. See *Cartilago cricoidea.*

CARTILA′GO ARYTÆNOIDE′A. See *Larynx.*

CARTILA′GO CRICOIDE′A. The cricoid cartilage belongs to the larynx, and is situated between the thyroid and arytenoid cartilages and the trachea; it constitutes, as it were, the basis of the many annular cartilages of the trachea.

CARTILA′GO ENSIFORMIS. *Cartilago xiphoidea.* Ensiform cartilage. A cartilage shaped somewhat like a sword or dagger, attached to the lowermost part of the sternum, just at the pit of the stomach.

Cartila′go scutifo′rmis. See *Thyroid cartilage.*

Cartila′go thyroide′a. See *Thyroid cartilage.*

Cartila′go xiphoide′a. See *Cartilago ensiformis.*

CA′RUI. (*Caruia*, Arabian.) The caraway. See *Carum.*

CA′RUM. (Καρος: so named from *Caria*, a province of Asia.) The caraway.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

2. The pharmacopœial name of the caraway plant. See *Carum carui.*

Ca′rum ca′rui. The systematic name for the plant whose seeds are called caraways. It is also called *Carvi. Cuminum pratense. Carus. Caruon.* The *Carum carui* of Linnæus. The seeds are well known to have a pleasant spicy smell, and a warm aromatic taste; and, on this account, are used for various economical purposes. They are esteemed to be carminative, cordial, and stomachic, and recommended in dyspepsia, flatulencies, and other symptoms attending hysterical, and hypocondriacal disorders. An essential oil and distilled water are directed to be prepared from them by the London college.

CA′RUNCLE. *Caruncula.* (Diminutive of *caro*, flesh.) A little fleshy excrescence; as the carunculæ myrtiformes, carunculæ lachrymales, &c.

CARU′NCULA LACHRYMA′LIS. A long conoidal gland, red externally, situated in the internal canthus of each eye, before the union of the eyelids. It appears to be formed of numerous sebaceous glands, from which many small hairs grow. The hardened smegma observable in this part of the eye in the morning, is separated by this caruncle.

Caru′nculæ cuticula′res alæ. The nymphæ.

Caru′nculæ mamilla′res. The extremities of the tubes in the nipple.

CARU′NCULÆ MYRTIFO′RMES. When the hymen has been lacerated by attrition, there remain in its place, two, three, or four caruncles, which have received the name of myrtiform.

Caru′nculæ papilla′res. The protuberances within the pelvis of the kidney, formed by the papillous substance of the kidney.

Carunculo′sa ischu′ria. A suppression of urine, from caruncles in the urethra.

Ca′ruon. See *Carum.*

Ca′rus. (Καρος: from *καρα*, the head, as being the part affected.) *Caros. Carosis.*

1. Insensibility and sleepiness, as in apoplexy, but attended with quiet respiration.

2. A profound sleep, without fever. A lethargy.

3. The caraway-seed.

Ca′rva. The cassia lignea.

Carye′don. (From *καρυα*, a nut.) *Carydon.* A sort of fracture, where the bone is broken into small pieces, like the shell of a cracked nut.

Cary′don. See *Caryedon.*

Caryocosti′num. An electuary, named from two of its ingredients, the clove and costus.

CARYOPHYLLA′TA. (From *καρυοφυλλον*, the caryophyllus; so named because it smells like the caryophyllus, or clove July flower.) See *Geum urbanum.*

Caryophylloi′des co′rtex. See *Laurus Culilawan.*

CARYOPHY′LLUM. (Καρυοφυλλον: from *καρυον*, a nut, and *φυλλον*, a leaf; so named because it was supposed to be the leaf of the Indian nut.) The clove.

CARYOPHY′LLUM AROMA′TICUM. The same. See *Eugenia Caryophyllata.*

Caryophy′llum ru′brum. The clove pink. See *Dianthus caryophyllus.*

CARYOPHY′LLUS. The clove-tree. The name of a genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Monogynia.* See *Eugenia Carophyllata.*

Caryophy′llus aroma′ticus America′nus. The piper Jamaicencis.

Caryophy′llus horte′nsis. The caryophyllum rubrum.

Caryophy′llus vulga′ris. The caryophyllata.

Caryo′tis. (From *καρυον*, a nut.) *Caryota.* Galen uses this word to mean a superior sort of dates, of the shape of a nut.

CASCARI′LLA. (Dim. of *cascara*, the bark, or shell. Span.) A name given originally to small specimens of cinchona: but now applied to the bark of the *Croton cascarilla*; which see.

Ca′schu. See *Acacia Catechu.*

Cashew-nut. See *Anacardium occidentale.*

Cashoo. An aromatic drug of Hindostan, said to possess pectoral virtues.

Ca′sia. See *Cassia.*

Casmina′ris. The cassumuniar of Bengal.

Ca′ssa. (Arab.) The thorax or breast.

Cassa′da. *Cassava.* See *Jatropha Manihot.*

Ca′ssamum. The fruit of the balsam tree.

CASSEBOHM, Frederic, a professor of anatomy at Halle in Saxony, published in 1730, a treatise on the difference between the Fœtus and Adult, in which he notices the descent of the testicle from the abdomen; and four years after a very minute and exact description of the ear. He likewise explained in subsequent publications the manner of dissecting the muscles and the viscera: but an early death prevented his completing his design of elucidating the anatomy of the whole body in the same way.

CASSERIUS, Julius, was born of humble parents at Placentia in 1545. He became servant to Fabricius at Padua, who observing his talent, first taught him anatomy, then made him his assistant, and finally coadjutor in the professorship in 1609. He pursued the study with uncommon zeal, expending almost all his profits in procuring subjects, and in having drawings and prints made of the parts, which he discovered, or traced more accurately than his predecessors. He employed comparative anatomy, not as a substitute for, but only as a clue to that of the human subject. He published an account of the organs of voice and hearing, which he afterwards extended to the other senses explaining also the uses of these parts. Some years after his death in 1616, the rest of his plates, amounting to 78, with the explanations, were published with the works of Spigelius.

CA′SSIA. (From the Arabic *katsia*, which is from *katsa*, to tear off; so called from the act of stripping the bark from the tree.) The name of a genus of plants in the Linnæan system. Class, *Decandria*. Order, *Monogynia*. Cassia and Senna belong to this genus.

Ca′ssia Caryophylla′ta. The clove-bark tree. See *Myrtus Caryophyllata*.

Ca′ssia fi′stula. *Cassia nigra. Cassia fistularis. Alexandrina. Chaiarxambar. Canna. Cassia solutiva. Tlai Xiem.* Purging cassia. This tree, *Cassia fistula; foliis quinquejugis ovatis acuminatis glabris, petiolis eglandulatis* of Linnæus, is a native of both Indies. The pods of the East India cassia are of a less diameter, smoother, and afford a blacker, sweeter, and more grateful pulp, than those which are brought from the West Indies. Those pods which are the heaviest, and in which the seeds do not rattle on being shaken, are commonly the best, and contain the most pulp, which is the part medicinally employed, and to be obtained in the manner described in the pharmacopœias. The best pulp is of a bright shining black colour, and of a sweet taste, with a slight degree of acidity. It has been long used as a laxative medicine, and being gentle in its operation, and seldom disturbing the bowels, is well adapted to children, and to delicate or pregnant women. Adults, however, find it of little effect, unless taken in a very large dose, as an ounce or more; and, therefore, to them this pulp is rarely given, but usually conjoined with some of the brisker purgatives. The officinal preparation of this drug, is the confectio cassiæ; it is also an ingredient in the confectio sennæ.

Ca′ssia fistula′ris. See *Cassia fistula*.

Ca′ssia li′gnea. Cassia bark. See *Laurus cassia*.

Ca′ssia ni′gra. See *Cassia fistula*.

Cassia, purging. See *Cassia fistula*.

Ca′ssia senna. The systematic name of the plant, which affords senna. *Senna alexandrina. Senna italica.* Senna, or Egyptian cassia. *Cassia; foliis sejugis subovatis, petiolis eglandulatis* of Linnæus. The leaves of senna, which are imported here from Alexandria for medicinal use, have a rather disagreeable smell, and a subacrid, bitterish, nauseous taste. They are in common use as a purgative. The formulæ given of the senna by the colleges, are an infusion, a compound powder, a tincture, and an electuary. See *Infusum sennæ*, &c.

Ca′ssia soluti′va. See *Cassia fistula*.

Ca′ssiæ arame′ntum. The pulp of cassia.

Ca′ssiæ flo′res. What are called cassia flowers in the shops, are the flowers of the true cinnamon tree, *Laurus cinnamomum* of Linnæus. They possess aromatic and astringent virtues, and may be successfully employed in decoctions, &c. in all cases where cinnamon is recommended. See *Laurus cinnamomum*.

Ca′ssiæ pu′lpa. See *Cassia fistula*.

Ca′ssob. An obsolete term for kali.

Cassole′ta. Warm fumigations described by Marcellus.

Cassonada. Sugar.

Cassummu′niar. (Of uncertain derivation, perhaps Indian.) *Casamunar. Casmina. Risagon. Bengale Indorum.* The root, occasionally exhibited under one of these names, is brought from the East Indies. It comes over in irregular slices of various forms, some cut transversely, others longitudinally. The cortical part is marked with circles of a dusky brown colour: the internal part is paler, and unequally yellow. It possesses moderately warm, bitter, and aromatic qualities, and a smell like ginger. It is recommended in hysterical, epileptic, and paralytic affections.

CASTA′NEA. (*καϛανον*: from *Castana*, a city in Thessaly, whence they were brought.) The common chesnut. See *Fagus castanea*.

Casta′nea equi′na. The horse-chesnut. See *Æsculus Hippocastanum*.

Castánea flóre álbo. Coffee.

CASTELLANUS, Peter, or Du Chatel, was born at Grammont in Flanders, 1585. His rapid improvement in the Greek language procured him the professorship, at Lovain, in 1609; but he did not graduate in medicine till nine years after. At the same period, he published the lives of eminent physicians in Latin, written in a concise but very entertaining manner, with useful references to the original authorities. He died in 1632.

CASTELLUS, Bartholomew, an Italian physician, who practised at Messina about the end of the 16th century. He was author of two works, both for a long time extremely popular, a Synopsis of Medicine, and "Lexicon Medicum Græco-Latinum," in which great learning and judgment are conspicuous.

Castle-leod waters. A sulphureous

spring in Ross-shire, celebrated for the cure of cutaneous diseases and foul ulcers.

Ca′stor fi′ber. The systematic name of the beaver. See *Castoreum.*

Castor. See *Castoreum.*

Castor oil. See *Ricinus.*

Castor, Russian. See *Castoreum.*

CASTORE′UM. (*Castor* from καϛωρ, the beaver, *quasi* γαϛωρ: from γαϛηρ, the belly: because of the largeness of its belly; or *à castrando,* because he was said to castrate himself in order to escape the hunters.) *Castoreum russicum.* A peculiar concrete substance, called castor, is obtained from the *Castor fiber* of Linnæus, or beaver, an amphibious quadruped inhabiting some parts of Prussia, Russia, Germany, &c.; but the greatest number of these animals is met with in Canada. The name of *castoreum* or castor is given to two bags, situated in the inguinal regions of the beaver, which contain a very odorous substance, soft, and almost fluid when recently cut from the animal, but which dries, and assumes a resinous consistence in process of time. The best comes from Russia. This substance has an acrid, bitter, and nauseous taste; its smell is strong and aromatic, yet at the same time fœtid. It is used medicinally, as a powerful antispasmodic in hysterica and hypochondriacal affections, and in convulsions, in doses of from 10 to 30 grains. It has also been successfully administered in epilepsy and tetanus. It is occasionally adulterated with dried blood, gum-ammoniacum, or galbanum, mixed with a little o the powder of castor, and some quantity of the fat of the beaver.

Castori′um. See *Castoreum.*

CASTRATION. *Celotomia. Orchotomia.* A chirurgical operation, by which a testicle is removed from the body.

Castre′nsis. (From *castra,* a camp.) A name applied to those diseases with which soldiers, encamped in marshy places, are afflicted.

Cata′basis. (From καταϐαινω, to descend.) A descent or operation downwards.

Catabi′basis. (From καταϐιϐαζω, to cause to descend.) An exclusion, or expulsion of the humours downwards.

Catablaceu′sis. (From καταϐλακευω, to be useless.) Hippocrates uses this word to signify carelessness and negligence in the attendance on and administration to the sick.

Catable′ma. (From καταϐαλλω, to throw round.) The outermost fillet, which secures the rest of the bandages.

Catabronche′sis. (From κατα, and βρογχος, the throat; or καταϐρογχιζω, to swallow.) The act of swallowing.

Catacau′ma. (From κατακαιω, to burn.) A burn or scald.

Catacau′sis. (From κατακαιω, to burn.) The act of combustion, or burning.

Catacecli′menus. (From κατακλινομαι, to lie down.) Keeping the bed, from the violence of a disease.

Catacecra′menus. (From κατακεραννομι, to reduce to small particles.) Broken into small pieces. It is used of fractures.

Catacera′stica. (From κατακεραννυμι, to mix together.) Medicines which obtund the acrimony of humours, by mixing with them and reducing them.

Catachlide′sis. (From καταχλιδαω, to indulge in delicacies.) A gluttonous indulgence in sloth and delicacies, to the generation of diseases.

Catachri′ston. (From καταχριω, to anoint.) An unguent, or ointment.

Catachri′sma. An ointment.

Cata′clasis. (From κατακλαω, to break, or distort.) Distorted eyelids.

Ca′tacleis. *Catacleïs.* (From κατα, beneath, and κλεις, the clavicle.) The subclavicle, or first rib, which is placed immediately under the clavicle.

Catacli′nes. (From κατακλινω, to lie down.) One who, by disease, is fixed to his bed.

Cata′clisis. (From κατακλινω, to lie down.) A lying down. It means also incurvation.

Catacly′sma. (From κατακλυζω, to wash.) A clyster.

Catacly′smus. (From κατακλυζω, to wash.) An embrocation. A dashing of water upon any part.

Catacre′mnos. (From κατα, and κρημνος, a precipice.) Hippocrates means, by this word, a swoln and inflamed throat, from the exuberance of the parts.

Catacru′sis. (From κατακρουω, to drive back.) A revulsion of humours.

Catadoule′sis. (From καταδουλοω, to enslave.) The subduing of passions, as in a phrensy, or fever.

Catægize′sis. (From καταιγιζω, to repel.) A revulsion or rushing back of humours, or wind in the intestines.

Catæone′sis. (From καταιονεω, to irrigate.) Irrigation by a plentiful affusion of liquor on some part of the body.

Cata′gma. (From κατα, and αγω, to break.) A fracture. Galen says a solution of the bone is called catagma, and elcos is a solution of the continuity of the flesh: that when it happens to a cartilage, it has no name, though Hippocrates calls it catagma.

Catagma′tica. (From καταγμα, a fracture.) Catagmatics. Remedies proper for cementing broken bones, or to promote a callus.

Catago′ge. (From καταγομαι, to abide.) The seat or region of a disease or part.

Catagyio′sis. (From καταγυιοω, to debilitate.) An imbecility and enervation of the strength and limbs.

CATALE′PSIS. (From καταλαμϐανω, to seize, to hold.) *Catoche. Catochus. Congelatio. Detentio. Encatalepsis;* and by Hippocrates *aphonia;* by Antigenes *anaudia;* by Cælius Aurelianus *apprehensio, oppressio; comprehensio. Apoplexia cataleptica* of Cullen. Catalepsy. A sudden suppression of motion and sensation, the body remaining in the same posture that it was in when seized.

Dr. Cullen says, he has never seen the catalepsy except when counterfeited; and is of opinion, that many of those cases related by other authors, have also been counterfeited. It is said to come on suddenly, being only preceded by some languor of body and mind, and to return by paroxysms. The patients are said to be for some minutes, sometimes (though rarely) for some hours, deprived of their senses, and all power of voluntary motion; but constantly retaining the position in which they were first seized, whether lying or sitting; and if the limbs be put into any other posture during the fit, they will keep the posture in which they are placed. When they recover from the paroxysm, they remember nothing of what passed during the time of it, but are like persons awakened out of a sleep.

Catalo′tica. (From *καταλοαω*, to grind down.) Medicines to soften and make smooth the rough edges and crust of cicatrices.

Cata′lysis. (Καταλυσις: from *καταλυω*, to dissolve or destroy.) It signifies a palsy, or such a resolution as happens before the death of the patient; also that dissolution which constitutes death.

Catamara′smus. (From *καταμαραινω*, to grow thin.) An emaciation, or resolution of tumours.

Catamasse′sis. (From *καταμασσομαι*, to manducate.) The grinding of the teeth, and biting of the tongue; so common in epileptic persons.

CATAME′NIA. (*Catamenia, -orum*, neut. plur. from *κατα*, according to, and *μην*, the month.) *Menses.* The monthly discharge from the uterus of females, between the ages of 14 and 45. Many have questioned whether this discharge arose from a mere rupture of vessels, or whether it was owing to a secretory action. There can be little doubt of the truth of the latter. The secretory organ is composed of the arterial vessels situated in the fundus of the uterus. The dissection of women, who have died during the time of their menstruating, proves this. Sometimes, though very rarely, women, during pregnancy, menstruate; and when this happens, the discharge takes place from the arterial vessels of the vagina. During pregnancy and lactation, when the person is in good health, the catamenia, for the most part, cease to flow. The quantity a female menstruates at each time, is very various; depending on climate, and a variety of other circumstances. It is commonly in England, from five to six ounces; it rarely exceeds eight. Its duration is from three to four, and sometimes, though rarely, five days. With respect to the nature of the discharge, it differs very much from pure blood; it never coagulates, but is sometimes grumous, and membranes like the decidua are formed in difficult menstruations: in some women it always smells rank and peculiar; in others it is inodorous. The use of this monthly secretion is to render the uterus fit for the conception and nutrition of the fœtus; therefore girls rarely conceive before the catamenia appear, and women rarely after their entire cessation; but very easily soon after menstruation.

Catana′nce. Succory.

Catani′phthis. (From *κατανιπτω*, to wash.) Washed, or scoured. It is used by Hippocrates of a diarrhœa washed and cleansed by boiled milk.

Catantle′ma. (From *καταντλαω*, to pour upon.) A lotion by infusion of water, or medicated fluids.

Catantle′sis. A medicated fluid.

Catapa′sma. (From *καταπασσω*, to sprinkle.) *Catapastum. Conspersio. Epipaston. Pasma. Sympasma. Aspersio. Aspergo.* The antient Greek physicians meant by this, any dry medicine reduced to powder, to be sprinkled on the body. Their various uses may be seen in Paul of Egina, lib. vii. cap. xiii.

Catapau′sis. (From *καταπαυω*, to rest, or cease.) That rest or cessation from pain which proceeds from the resolution of uneasy tumours.

Catape′ltes. (From *κατα*, against, and *πελτη*, a shield.) This word means a sling, a granado, or battery; and is also used to signify the medicine which heals the wounds and bruises made by such an instrument.

Cata′phora. (From *καταφερω*, to make sleepy.) *Coma somnolentum.* A preternatural propensity to sleep. A mild apoplexy.

Cata′phora arthri′tica. Apoplexy from gout.

Cata′phora co′ma. Sanguineous apoplexy.

Cata′phora exanthema′tica. A lethargy in eruptive diseases.

Cata′phora hydrocepha′lica. Serous apoplexy.

Cata′phora scorbu′tica. Apoplectic symptoms in scurvy.

Cata′phora ti′mor. A lethargic disposition.

Cataphra′cta. (From *καταφρασσω*, to fortify.) A bandage on the thorax.

CATAPLA′SMA. (*-matis*, neut. from *καταπλασσω*, to spread like a plaster.) A poultice. The following are among the most useful.

Catapla′sma alu′minis. This application was formerly used to inflammation of the eyes, which was kept up from weakness of the vessels; it is now seldom used, a solution of alum being mostly substituted.

Catapla′sma aceto′sæ. Sorrel poultice; ℞. Acetosæ, ℔j. To be beaten in a mortar into a pulp. A good application to scorbutic ulcers.

Catapla′sma aëra′tum. See *Cataplasma fermenti.*

Catapla′sma coni′i. Hemlock poultice.

℞. Conii foliorum exsiccatorum ℥j. Aquæ fontanæ, ℔jj. To be boiled till only a pint remains, when as much linseed-meal as necessary is to be added. This is an excellent application to many cancerous and scrophulous ulcers, and other malignant ones; frequently producing great diminution of the pain of such diseases, and improving their appearance. Justamond preferred the fresh herb bruised.

Catapla′sma cumi′ni. Take of cumin seeds, one pound; bay berries, the leaves of water germander dried, Virginia snakeroot, of each three ounces; cloves, one ounce; with honey equal to thrice the weight of the powder formed, of these make a cataplasm. It was formerly called Theriaca Londinensis. This is a warm and stimulating poultice, and was formerly much used as an irritating antiseptic application to gangrenous ulcers, and the like. It is now seldom ordered.

Catapla′sma dau′ci. Carrot poultice. ℞. Radicis dauci recentis, ℔j. Bruise it in a mortar into a pulp. Some, perhaps with reason, recommend the carrots to be first boiled. The carrot poultice is employed as an application to ulcerated cancers, scrophulous sores of an irritable kind, and various inveterate malignant ulcers.

Catapla′sma ferme′nti. Yest cataplasm. Take of flour a pound; yest half a pint. Mix and expose to a gentle heat, until the mixture begins to rise. This is a celebrated application in cases of sloughing and mortification.

Catapla′sma fu′ci. This is prepared by bruising a quantity of the marine plant, commonly called sea-tang, which is afterwards to be applied by way of a poultice. Its chief use is in cases of scrophula, white swellings, and glandular tumours more especially. When this vegetable cannot be obtained in its recent state, a common poultice of sea-water and oatmeal has been substituted by the late Mr. Hunter, and other surgeons of eminence.

Catapla′sma li′ni. Linseed poultice. ℞. Farinæ lini, ℔ss. Aquæ ferventis, ℔jss. The powder is to be gradually sprinkled into the water, while they are quickly blended together with a spoon. This is the best and most convenient of all emollient poultices for common cases, and has, in a great measure, superseded the bread and milk one, so much in use formerly.

Catapla′sma plu′mbi aceta′tis. ℞. Liquoris plumbi acetatis ʒj. Aquæ distill. ℔j. Micæ panis, q. s. Misce. Practitioners, who place much confidence in the virtues of lead, often use this poultice in cases of inflammation.

Catapla′sma sina′peos. See *Cataplasma sinapis.*

Catapla′sma sina′pis. Mustard cataplasm. Take of mustard-seed, linseed, of each powdered half a pound; boiling vinegar, as much as is sufficient. Mix until it acquires the consistence of a cataplasm.

Catapl͏e′xis. (From *κατα* and *πλησσω*, to strike.) Any sudden stupefaction, or deprivation of sensation, in any of the members, or organs.

Catapo′sis. (From *καταπινω*, to swallow down.) According to Aretæus, it signifies the instruments of deglutition. Hence also catapotium.

Catapo′tium. (Καταποτιον.) A pill.

Catapsy′xis. (From ψυχω, to refrigerate.) A refrigeration without shivering, either universal, or of some particular part. A chilliness, or, as Vogel defines it, an uneasy sense of cold in a muscular or cutaneous part.

Catapto′sis. (From *καταπιπτω*, to fall down.) It implies such a falling down as happens in apoplexies; or the spontaneous falling down of a paralytic limb.

Catapu′tia. (From *καλαπυθω*, to have an ill savour; or from the Italian, *cacapuzza*, which has the same meaning; so named from its fœtid smell.) Spurge.

Catapu′tia ma′jor. See *Ricinus.*

Catapu′tia mi′nor. See *Euphorbia Lathyris.*

CA′TARACT. (*Cataracta;* from *καταρασσω*, to confound or disturb; because the sense of vision is confounded, if not destroyed.) A disease of the eye. The *Caligo lentis* of Cullen. Hippocrates calls it *γλαυκωμα*. Galen, *υποχυμα*. The Arabians, *gutta opacu*. Celsus, *suffusio*. It is a species of blindness, arising almost always from an opacity of the crystalline lens, or its capsule, preventing the rays of light passing to the optic nerve. It commonly begins with a dimness of sight; and this generally continues a considerable time before any opacity can be observed in the lens. As the disease advances, the opacity becomes sensible, and the patient imagines there are particles of dust, or motes, upon the eye, or in the air, which are called *muscæ volitantes*. This opacity gradually increases, till the person either becomes entirely blind, or can merely distinguish light from darkness. The disease commonly comes on rapidly, though sometimes its progress is slow and gradual. From a transparent state, it changes to a perfectly white, or light grey colour. In some very rare instances, a black cataract is found. The consistence also varies, being at one time hard, at another entirely dissolved. When the opaque lens is either more indurated than in the natural state, or retains a tolerable degree of firmness, the case is termed a *firm* or hard cataract. When the substance of the lens seems to be converted into a whitish or other kind of fluid, lodged in the capsule, the case is denominated a *milky* or *fluid cataract*. When the substance is of a middling consistence, neither hard nor fluid, but about as consistent as a thick jelly, or curds, the case is named a *soft* or caseous cataract.

When the anterior or posterior layer of the crystalline capsule becomes opaque, after the lens itself has been removed from this little membranous sac, by a previous operation, the affection is named a *secondary membranous cataract.* There are many other distinctions made by authors. Cataract is seldom attended with pain; sometimes, however, every exposure to light creates uneasiness, owing probably to the inflammation at the bottom of the eye. The real cause of cataract is not yet well understood. Numbers of authors consider it as proceeding from a preternatural contraction of the vessels of the lens, arising from some external violence, though more commonly from some internal and occult cause. The cataract is distinguished from gutta serena, by the pupils in the latter being never affected with light, and from no opacity being observed in the lens. It is distinguished from hypopyon, staphyloma, or any other disease in the fore-part of the eye, by the evident marks which these affections produce, as well as by the pain attending their beginning. But it is difficult to determine when the opacity is in the lens, or in its capsule. If the retina (which is an expansion of the optic nerve in the inside of the eye) be not diseased, vision may, in most cases, be restored, by either depressing the diseased lens, which is termed couching, or extracting it.

Catarrheu'ma. (From *καταρρεω*, to flow from.) A catarrh, or defluxion of humours.

Catarrhe'xis. (From *καταρρηγνυω*, to burst out.) A violent and copious eruption or effusion; joined with *κοιλιας*, it is a copious evacuation from the belly, and sometimes alone it is of the same signification. In Vogel's Nosology, it is defined, a discharge of pure blood from the intestines, such as takes place in dysentery.

Catarrhœcus. (From *καταρρεω*, to flow from.) A word applied to diseases proceeding from a discharge of phlegm.

Cata'rropa phy'mata. (*Καταρροπα φυματα.*) Tubercles tending downward; or, as Galen states, those that have their apex on a depending part.

Cata'rrhopos nou'sos. (*Καταρροπος νουσος.*) A remission of the disease, or its decline, opposed to the paroxysm.

CATA'RRHUS. (From *καταρρεω*, to flow down.) *Coryza.* A catarrh. An increased secretion of mucus from the membranes of the nose, fauces, and bronchia, with fever, and attended with sneezing, cough, thirst, lassitude, and want of appetite. It is a genus of disease in the class *pyrexiæ,* and order *profluvia,* of Cullen. There are two species of catarrh, viz. *catarrhus à frigore,* which is very common, and is called a cold in the head; and *catarrhus à contagio,* the influenza, or epidemic catarrh, which sometimes seizes a whole city. Catarrh is also symptomatic of several other diseases. Hence we have the *catarrhus rubeolosus; tussis variolosa, verminosa, calculosa, phthisica, hysterica, à dentitione, gravidarum, metallicolarum,* &c.

Catarrh is seldom fatal, except in scrophulous habits by laying the foundation of phthisis; or where it is aggravated by improper treatment, or repeated exposure to cold, into some degree of peripneumony; when there is hazard of the patient, particularly if advanced in life, being suffocated by the copious effusion of viscid matter into the air-passages. The epidemic is generally, but not invariably, more severe than the common form of the disease. The latter is usually left to subside spontaneously, which will commonly happen in a few days, by observing the antiphlogistic regimen. If there should be fixed pain of the chest, with any hardness of the pulse, a little blood may be taken from the arm, or topically, followed by a blister: the bowels must be kept regular, and diaphoretics exhibited, with demulcents and mild opiates to quiet the cough. Where the disease hangs about the patient in a chronic form, gentle tonics and expectorants are required, as myrrh, squill, &c. In the epidemic catarrh more active evacuations are often required, the lungs being more seriously affected; but though these should be promptly employed, they must not be carried too far, the disease being apt to assume the typhoid character in its progress: and as the chief danger appears to be of suffocation happening from the cause above-mentioned, it is especially important to promote expectoration, first by antimonials, afterwards by squill, the inhalation of steam, &c. not neglecting to support the strength of the patient as the disease advances.

Cata'rrhus a fri'gore. Catarrh from cold.

Cata'rrhus bellinsula'nus. Mumps, or cynanche parotidæa.

Cata'rrhus a conta'gio. The influenza.

Cata'rrhus suffocati'vus. The croup, or cynanche trachealis.

Cata'rrhus vesi'cæ. Strangury, with discharge of mucus.

Catarti'smus. (From *καταρτιζω*, to make perfect.) According to Galen, it is a translation of a bone from a preternatural to its natural situation.

Catasa'rca. (From *κατα*, and *σαρξ*, flesh.) The same as *Anasarca.*

Catasbe'stis. (From *κατα*, and *σϐεννυμι*, to extinguish.) The resolution of tumours without suppuration.

Catascha'smus. (From *κατασχαζω*, to scarify.) Scarification.

Catasei'sis. (From *κατα*, and *σειω*, to shake.) A concussion.

Cataspa'sma. (From *κατασπαω*, to draw backwards.) A revulsion or retraction of humours, or parts.

Catasta'gmos. (From *κατα*, and *ϛαζω*

to distil.) This is the name which the Greeks, in the time of Celsus, had for a distillation.

Catasta'lticus. (From *καταστελλω*, to restrain, or contract.) It signifies styptic, astringent, repressing.

Cata'stasis. (*Καταστασις.*) The constitution, state, or condition of any thing.

Cata'tasis. (From *κατατεινω*, to extend.) In Hippocrates it means the extension of a fractured limb, or a dislocated one, in order to replace it. Also the actual replacing it in a proper situation.

Cata'xis. (From *καταγω*, to break.) A fracture. Also a division of parts by an instrument.

Catecho'menus. (From *κατεχω*, to resist.) Resisting and making ineffectual the remedies which have been applied or given.

CA'TECHU. (It is said, that, in the Japanese language, *kate* signifies a tree, and *chu*, juice.) See *Acacia*.

Cateia'dion. (From *κωτα*, and *εια*, a blade of grass.) An instrument, having at the end a blade of grass, or made like a blade of grass, which was thrust into the nostrils to provoke an hæmorrhage when the head ached. It is mentioned by Aretæus.

Cate'llus. (Dim. of *catulus*, a whelp.) A young whelp. Also a chemical instrument called a cupel, which was formerly in the shape of a dog's head.

Cathæ'resis. (From *καθαιρω*, to take away.) The subtraction or taking away any part or thing from the body. Sometimes it means an evacuation, and Hippocrates uses it for such. A consumption of the body, as happens without manifest evacuation.

Cathære'tica. (From *καθαιρω*, to take away.) Medicines which consume or remove superfluous flesh.

Catha'rma. (From *καθαιρω*, to remove.) The excrements, or humours, purged off from the body.

Catha'rmus. (From *καθαιρω*, to remove.) A purgation of the excrements, or humours. A cure by incantation, or the royal touch.

Catha'rsia. (From *καθαιρω*, to purge.) Cathartics, having a purging property.

CATHA'RSIS. (From *καθαιρω*, to take away.) A purge, or purgation of the excrements, or humours, either medically or naturally.

CATHA'RTICS. (*Cathartica*, sc. *medicamenta*; *καθαρτικα*: from *καθαιρω*, to purge.) Those medicines which, taken internally, increase the number of alvine evacuations. The different articles referred to this class of medicines are divided into five orders.

1. *Stimulating cathartics*, as jalap, aloes, and bitter apple, which are well calculated to discharge accumulations of serum, and are mostly selected for indolent and phlegmatic habits, and those who are hard to purge.

2. *Refrigerating cathartics*, as sulphate of soda, supertartrate of potash, &c. These are better adapted for plethoric habits, and those with an inflammatory diathesis.

3. *Adstringent cathartics*, as rhubarb and damask roses, which are mostly given to those whose bowels are weak and irritable, and subject to diarrhœa.

4. *Emollient cathartics*, as manna, malva, castor oil, and olive oil, which may be given in preference to other cathartics, to infants and the very aged.

5. *Narcotic cathartics*, as tobacco, hyoscyamus, and digitalis. This order is never given but to the very strong and indolent, and to maniacal patients, as their operation is very powerful.

Murray, in his Materia Medica, considers the different cathartics under the two divisions of laxatives and purgatives; the former being mild in their operation, and merely evacuating the contents of the intestines; the latter being more powerful, and even extending their stimulant operation to the neighbouring parts. The following he enumerates among the principal laxatives: — Manna, Cassia fistula, Tamarindus Indica, Ricinus communis, Sulphur, Magnesia. Under the head of purgatives, he names Cassia senna, Rheum palmatum, Convolvulus jalapa, Helleborus niger, Bryonia alba, Cucumis colocynthis, Momordica elaterium, Rhamnus catharticus, Aloe perfoliata, Convolvulus scammonia, Gambogia, Submurias hydrargyri, Sulphas magnesiæ, Sulphas sodæ, Sulphas potassæ, Supertartras potassæ, Tartras potassæ, Tartras potassæ et sodæ, Phosphas sodæ, Murias sodæ, Terebinthina veneta, Nicotiana tabacum.

Catha'rticus sal. See *Sulphas magnesiæ*, and *Sulphas sodæ*.

Catha'rticus hispa'nicus sal. A kind of sulphate of soda, produced near Madrid, from some springs.

Catha'rticus Glaube'ri sal. See *Sodæ sulphas*.

Cathe'dra. (From *καθεζομαι*, to sit.) The anus, or rather, the whole of the buttocks, as being the part on which we sit.

Cathere'tica. (From *καθαιρω*, to remove.) Corrosives. Medicines, which, by corrosion, remove superfluous flesh.

CA'THETER. (*-teris*, m. *καθετηρ*; from *καθιημι*, to thrust into.) A long and hollow tube, that is introduced by surgeons into the urinary bladder, to remove the urine, when the person is unable to pass it. Catheters are either made of silver or of the elastic gum. That for the male urethra is much longer than that for the female, and so curved, if made of silver, as to adapt itself to the urethra.

CATHETERI'SMUS. (From *καθετηρ*, a catheter.) The term given by P. Ægineta to the operation of introducing the catheter.

Cathi′drysis. (From καθιδρυω, to place together.) The reduction of a fracture. The operation of setting a broken bone.

Ca′thmia. A name for litharge.

Ca′thodos. (From κατα, and οδος.) A descent of humours.

Catho′lceus. (From κατα, and ολκεω, to draw over.) An oblong fillet, made to draw over and cover the whole bandage of the head.

Catho′licon. (From κατα, and ολικος, universal.) A panacea, or universal medicine. A term formerly applied to medicines that were supposed to purge all the humours.

Cathy′pnia. (From κατα, and υπνος, sleep.) A profound but unhealthy sleep.

Ca′tias. (From καθιημι, to place in.) An incision knife, formerly used for opening an abscess in the uterus, and for extracting a dead fœtus.

Cati′llus. See *Catellus.*

Ca′tinum alu′men. A name given to potash.

Ca′tinus. (Κατανον.) A crucible.

Cátmint. See *Nepeta.*

Catocatha′rtica. (From κατω, downwards, and καθαιρω, to purge.) Medicines that operate by stool.

Ca′toche. (From κατεχω, to detain.) See *Catalepsis.*

Catochei′lum. (From κατω, beneath, and χειλος, the lip.) The lower lip.

Ca′tochus. (From κατεχω, to detain.) A catalepsy. Also a tetanus or spasmodic disease in which the body is rigidly held in an upright posture.

Ca′tochus cervi′nus. Tetanus, particularly affecting the neck.

Ca′tochus diu′rnus. An occasional tetanus.

Ca′tochus holoto′nicus. Another name for tetanus.

Catomi′smus. (From κατω, below, and ωμος, the shoulder.) By this word, P. Ægineta expresses a method of reducing a luxated shoulder, by raising the patient over the shoulder of a strong man, that by the weight of the body, the dislocation may be reduced.

Cato′psis. (From κατοπτομαι, to see clearly.) An acute and quick perception. The acuteness of the faculties which accompanies the latter stages of consumption.

Cato′pter. (From κατα, and οπτομαι, to see, and, by metaphor, to probe.) A probe. An instrument called a speculum ani.

Catorchi′tes. (From κατα, and ορχις, the orchis.) A wine in which the orchis root has been infused.

Catore′tica. (From κατω, downwards, and ρεω, to flow.) *Catoteretica. Catoterica.* Medicines which purge by stool.

Catotere′tica. See *Catoretica.*

Catulo′tica. (From κατουλοω, to cicatrize.) Medicines that cicatrize wounds.

Catutri′pali. A name of the piper longum.

Cau′calis. (From καυκιον, a cup; or from δαυκαλις, the daucus.) Bastard parsley, so named from the shape of its flower. Also the wild carrot.

Caucaloi′des. (From *caucalis,* and ειδος, a likeness; from its likeness to the flower of the caucalis.) The patella is sometimes so called.

CAU′DA. (From *cado,* to fall; because it hangs or falls down behind.) A tail.

1. The tail of animals.

2. A name formerly given to the os coccygis, that being in tailed animals the beginning of the tail.

3. A fleshy substance, projecting from the lips of the vagina, and resembling a tail, according to Aetius.

4. Many herbs are also named cauda, with the affixed name of some animal, whose tail the herb is supposed to be like; as cauda equina, horse-tail; cauda muris, mouse-tail; and in many other instances.

Cau′da equi′na. The spinal marrow, at its termination about the second lumbar vertebra, gives off a large number of nerves, which, when unravelled, resemble the horse's tail; hence the name. See also *Hippuris vulgaris.*

Cauda′tio. (From *cauda,* a tail.) An elongation of the clitoris.

CAUL. The English name for the omentum. See *Omentum.*

Caule′don. (From καυλος, a stalk.) A tranverse fracture, when the bone is broken, like the stump of a tree.

Cau′liflower. A species of brassica, whose flower is cut before the fructification expands.—The observations which have been made concerning cabbages are applicable here. See *Brassica capitata.* Cauliflower is, however, a far more delicious vegetable.

CAU′LIS. (Kalab. A Chaldean word.)

1. The stem or stalk of a plant.

2. A cabbage.

3. The penis of a man.

Cau′lis flo′rida. Cauliflower.

Caulo′des. (From καυλος, a stem.) The white or green cabbage.

Caulo′ton. (From καυλος, a stem; because it grows upon a stalk.) A name given to the beet.

Cau′ma. (From καιω, to burn.) The heat of the body, or the heat of the atmosphere, in a fever.

Cau′nga. A name of the areca.

Cau′sis. (From καιω, to burn.) A burn; or rather, the act of combustion, or burning.

Causo′des. (From καιω, to burn.) A term applied by Celsus to a burning fever.

Causo′ma. (From καιω, to burn.) An ardent or burning heat and inflammation. A term used by Hippocrates.

Caustic alkali. The pure alkalies are so called. See *Alkali.*

Caustic barley. See *Cevadilla.*

CAUSTICS. (*Caustica,* sc. *medicamenta*; from καιω, to burn; because they always produce a burning sensation.) See *Escharotics.*

Cau′sticum America′num. The cevadilla.

Cau′sticum antimonia′le. Muriate of antimony.

Cau′sticum commu′ne fo′rtius. See *Potassa cum calce.*

Cau′sticum luna′re. See *Argenti nitras.*

Cau′sus. (From καιω, to burn.) An highly ardent fever. According to Hippocrates, a fiery heat, insatiable thirst, a rough and black tongue, complexion yellowish, and the saliva bilious, are its peculiar characteristics. Others also are particular in describing it; but, whether antients or moderns, from what they relate, this fever is no other than a continued *ardent fever* in a bilious constitution. In it the heat of the body is intense; the breath is particularly fiery; the extremities are cold; the pulse is frequent and small; the heat is more violent internally than externally, and the whole soon ends in recovery or death.

Causus, endemial. The name given, by Dr. Mosely, to the yellow fever of the West Indies.

CAUTERY. (From καιω, to burn.) Cauteries were divided, by the antients, into *actual* and *potential;* but the term is now given only to the red-hot iron, or *actual cautery.* This was formerly the only means of preventing hæmorrhages from divided arteries, till the invention of the ligature. It was also used in diseases, with the same view as we employ a blister. *Potential* cautery was the name by which kali purum, or potassa, was distinguished in the former dispensatories of Edinburgh. Surgeons understand, by this term, any caustic application.

CA′VA. The name of a vein, and also of the pudendum muliebre. See *Veins.*

Cave′rna. (From *cavus,* hollow.) A cavern. Also a name of the pudendum muliebre.

Caviare. *Caviarium.* A food made of the hard roes of sturgeon, formed into cakes, and much esteemed by the Russians.

Cavi′cula. (Dim. of *cavilla.*) See *Cavilla.*

Cavi′lla. (From *cavus.*) The ankle, or hollow of the foot.

CA′VITAS. (From *cavus,* hollow.) Any cavity, or hollowness. The auricle of the heart was formerly called the cavitas innominata, the hollow without a name.

Cayenne pepper. See *Capsicum.*

Cazabi. See *Jatropha.*

CEANO′THUS. (From κεανωθος, quia κεει ανωθεν, because it pricks at the extreme part.) A genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

Ceano′thus America′nus. *Celastrus. Celastus.* Some noted Indians depend more on this than on the lobelia, for the cure of syphilis, and use it in the same manner as lobelia.

Cea′sma. (From κεω, to split, or divide.) *Ceasmus.* A fissure, or fragment.

Ce′ber. (Arab.) The agallochum. Also the capparis.

Cebipi′ra. (Indian.) A tree which grows in Brazil, decoctions of whose bark are used in baths and fomentations, to relieve pains in the limbs, and cutaneous diseases.

Ce′dar. See *Cedrinum lignum.*

Ce′dma. (From κεδαω, to disperse.) A defluxion, or rheumatic affection, scattered over the parts about the hips.

Ce′dra, esse′ntia de. See *Citrus medica.*

Ce′drinum li′gnum. Cedar, the wood of the *Pinus cedrus* of Linnæus. An odoriferous wood, more fragrant than that of the fir, but possessing similar virtues.

Cedri′tes. (From κεδρος, the cedar-tree.) Wine in which the resin which distils from the cedar-tree has been steeped.

Ce′drium. Cedar. It is also a name for common tar, in old writings.

Cedrome′la. The fruit of the citron-tree.

Cedrone′lla. Turkey baum.

Cedro′stis. (From κεδρος, the cedar-tree.) A name of the white bryony, which smells like the cedar.

Ce′drus. (From *Kedron,* a valley where they grew abundantly.) The *Pinus cedrus* of Linnæus, or the cedar-tree.

Ce′drus America′na. The arbor vitæ.

Ce′drus bacci′fera. The savine.

Cei′ria. (From κειρω, to abrade.) The tape-worm; so called from its excoriating and abrading the intestines.

Célandine. See *Chelidonium majus.*

Cela′strus. (From κελα, a dart, or pole, which it represents.) See *Ceanothus Americanus.*

Cela′stus. The same.

Ce′le. (From κηλη.) A tumour caused by the protusion of any soft part. Hence the compound terms hydrocele, bubonocele.

Ce′lery. The English name for a variety of the apium graveolens.

Celiac artery. See *Cœliac artery.*

Ce′lis. (From καιω, to burn.) A spot or blemish upon the skin, particularly that which is occasioned by a burn.

Ce′lla tu′rcica. See *Sella turcica.*

Ce′llula. (Dim. of *cella,* a cell.) A little cell, or cavity.

Ce′llulæ mastoide′æ. See *Temporal bones.*

CE′LLULAR ME′MBRANE. *Membrana cellulosa. Tela cellulosa. Panniculus adiposus. Membrana adiposa, pinguedinosa,* et *reticularis.* The cellular tissue of the body, composed of laminæ and fibres variously joined together, which is the connecting medium of every part of the body. It is by means of the communication of the cells of this membrane, that the butchers blow up their veal. The cellular membrane is, by some anatomists, distinguished into the reticular and adipose membrane. The former is evidently dispersed throughout the whole body, except the substance of the brain. It makes a bed for the other solids of the body, covers them all, and unites them one to another. The adipose membrane consists of the reticular substance, and a particular apparatus for the secretion of oil, and is mostly found immediately under the skin of many parts, and about the kidneys.

Celoto'mia. (From κηλη, hernia, and τεμνω, to cut.) The operation for hernia.

Ce'lsa. A term of Paracelsus, to signify what is called the beating of life in a particular part.

CE'LSUS, Aure'lius Corne'lius. It is commonly supposed, that this esteemed ancient author was a Roman, of the Cornelian family, born towards the end of the reign of Augustus, and still living in the time of Caligula. But these points are not established upon certain testimony, and it is even disputed whether he practised medicine; though his perfect acquaintance with the doctrines of his predecessors, his accurate descriptions of diseases, and his judicious rules of treatment, appear to leave little room for doubt on that head. At any rate his eight books, "De Medicina," have gained him deserved celebrity in modern times, containing a large fund of valuable information; detailed in remarkably elegant and concise language. In surgery particularly he has been greatly admired, for the methods of practice laid down, and for describing several operations, as they are still performed. There have been numerous editions of his work, and translations of it into the several modern languages.

Ceme'nterium. A crucible.

Ce'nchramis. (From κεγχρος, millet.) A grain or seed of the fig.

Ce'nchrius. A species of herpes that resembles κεγχρος, or millet.

Ceneangei'a. (From κενος, empty, and αγγος, a vessel.) The evacuation of blood, or other fluids, from their proper vessels.

Ceni'gdam. *Ceniplam. Cenigotam. Cenipolam.* The name of an instrument antiently used for opening the head in epilepsies.

Ceniote'mium. A purging remedy, formerly of use in the venereal disease, supposed to be mercurial.

Ceno'sis. (From κενος, empty.) Evacuation. It must be distinguished from *Catharsis*. *Cenosis* imports a general evacuation; *Catharsis* means the evacuation of a particular humour, which offends with respect to quality.

CENTAU'REA. (So called from *Chiron*, the centaur, who is said to have employed one of its species to cure himself of a wound accidentally received, by letting one of the arrows of Hercules fall upon his foot.) The name of a genus of plants in the Linnæan system, of the Order, *Polygamia frustanea*. Class, *Syngenesia*.

Centau'rea be'hen. The systematic name of the officinal *behen album*. *Jacea orientalis patula. Raphonticoides lutea.* The true white behen of the antients. The root possesses astringent virtues.

Centau'rea benedi'cta. The systematic name of the blessed thistle. *Carduus benedictus. Cnicus sylvestris.* Blessed or holy thistle. *Centaurea benedicta; calycibus duplicato-spinosis lanatis involucratis, foliis semidecurrentibus denticulato-spinosis* of Linnæus. This exotic plant, a native of Spain, and some of the Archipelago islands, obtained the name of Benedictus from its being supposed to possess extraordinary medicinal virtues. In loss of appetite, where the stomach was injured by irregularities, its good effects have been frequently experienced. It is a powerful bitter tonic and adstringent. Bergius considers it as antacid, corroborant, stomachic, sudorific, diuretic, and eccoprotic. Chamomile flowers are now generally substituted for the carduus benedictus, and are thought to be of at least equal value.

Centau'rea calcitra'pa. The systematic name of the calcitrapa. *Carduus stellatus. Jacea ramosissima, stellata, rupina.* Common star-thistle. Star-knapweed. The plant thus called in the pharmacopœias, is the *Centaurea calcitrapa; calycibus subduplicato-spinosis, sessilibus; foliis pinnatifidis, linearibus dentatis; caule piloso*, of Linnæus, every part of which is bitter. The juice, or extract, or infusion, are said to cure intermittents; and the bark of the root, and the seeds, have been recommended in nephritic disorders, and in suppression of urine. It scarcely differs, in its effects, from other bitters, and is now little used.

Centau'rea centau'rium. *Rhaponticum vulgare. Centaurium magnum. Centaurium majus.* Greater centaury. The root of this plant was formerly used as an aperient and corroborant in alvine fluxes. It is now totally discarded from the Materia Medica of this country.

Centau'rea cy'anus. The systematic name of the plant which affords the *flores cyani. Cyanus.* Blue-bottle. Corn-flower. The flowers of this plant, *Centaurea cyanus; calycibus serratis; foliis linearibus, integerrimis, infimis dentatis*, of Linnæus, were formerly in frequent use; but their antiphlogistic, antispasmodic, cordial, aperient, diuretic, and other properties are now, with great propriety, forgotten.

Centau'rea solstitia'lis. *Calcitrapa officinalis. Carduus stellatus luteus. Carduus solstitialis. Jacea stellata. Jacea lutea capite spinoso minori. Leucanthe veterum.* St. Barnaby's thistle. It is commended as an antiicteric, anti-cachectic, and lithontriptic, but is, in reality, only a weak tonic.

Centaurioi'des. The gratiola.

CENTAU′RIUM. (From κενταυρος, a centaur; so called because it was feigned that Chiron cured Hercules's foot, which he had wounded with a poisonous arrow, with it.) Centaury. See *Chironia Centaurium.*

Centau′rium ma′gnum.
Centau′rium ma′jus. } See *Centaurea Centaurium*

Centau′rium mi′nus. See *Chironia Centaurium.*

Centau′ry. See *Chironia.*

Centimo′rbia. (From *centum*, a hundred, and *morbus*, a disease.) Nummularia, or moneywort; named from its supposed efficacy in the cure of a multitude of disorders.

Centino′dia. (From *centum*, a hundred, and *nodus*, a knot.) The herb polygonum; so called from its many knots, or joints.

Centi′pedes. (From *centum*, a hundred, and *pes*, a foot.) Woodlice, named from the multitude of their feet.

Centra′tio. (From *centrum*, a centre.) The concentration and affinity of certain substances to each other. Paracelsus expresses by it the degenerating of a saline principle, and contracting a corrosive and exulcerating quality. Hence *Centrum Salis* is said to be the principle and cause of ulcers.

Ce′ntrium. (From κεντεω, to prick.) A plaster recommended by Galen against stitches and pricks in the side.

Ce′ntrum. (From κεντεω, to point or prick.) The middle point of a circle. In chemistry, it is the residence or foundation of matter. In medicine, it is the point in which its virtue resides. In anatomy, the middle point of some parts is so named, as *centrum nerveum*, the middle or tendinous part of the diaphragm.

CE′NTRUM OVA′LE. When the two hemispheres of the brain are removed on a line with a level of the *corpus callosum*, the internal medullary part presents a somewhat oval centre; hence it is called *centrum ovale.* Vieussenius supposed all the medullary fibres met at this place.

Ce′ntrum tendino′sum. The tendinous centre of the diaphragm is so called. See *Diaphragm.*

Ce′ntrum ne′rveum. The centre of the diaphragm is so called. See *Diaphragm.*

Centumno′dia. (From *centum*, a hundred, and *nodus*, a knot; so called from its many knots, or joints.) Common knot-grass. See *Polygonum aviculare.*

Centu′nculus. Bastard pimpernel.

CE′PA. (From κηπος, a woolcard, from the likeness of its roots.) The onion. See *Allium cepa.*

Cepæ′a. A species of onion which used to be esteemed for salads in spring, but is now disregarded.

Cephalæ′a. (From κεφαλη, the head.) The flesh of the head which covers the skull. Also a long-continued pain of the cerebrum, and its membranes.

CEPHALA′LGIA. (From κεφαλη, the head, and αλγος, pain.) *Cephalæa.* The head-ache. It is symptomatic of very many diseases, but is rarely an original disease itself. When mild, it is called cephalalgia; when inveterate, cephalæa. When one side of the head only is affected, it takes the names of *hemicrania*, *migrana*, *hemipagia*, and *megrim*; in one of the temples only, *crotaphos*; and that which is fixed to a point, generally in the crown of the head, is distinguished by the name of *clavus.*

Cephala′lgia catarrha′lis. Head-ache, with catarrh, from cold.

Cephala′lgia inflammato′ria. Phrenitis, or inflammation of the brain.

Cephala′lgia spasmo′dica. The sick head-ache. A species of indigestion.

Cephala′rtica. (From κεφαλη, the head, and αρτιζω, to make pure.) Medicines which purge the head.

CE′PHALE. (Κεφαλη.) The head.

CEPHALIC VEIN. (*Vena cephalica;* so called, because the head was supposed to be relieved by opening it.) The anterior vein of the arm, that receives the cephalic of the thumb.

CEPHA′LICA. (From κεφαλη, the head.) Cephalics. Such remedies as are adapted for the cure of disorders of the head. Of this class are the snuffs, which produce a discharge from the mucous membrane of the nose, &c.

Cepha′lica po′llicis. A branch from the cephalic vein, sent off from about the lower extremity of the radius, running superficially between the thumb and the metacarpus.

Cepha′licus pu′lvis. A powder prepared from asarum.

Cephali′ne. (From κεφαλη, the head.) The head of the tongue. That part of the tongue which is next the root, and nearest the fauces.

CEPHALI′TIS. (From κεφαλη, the head.) Inflammation of the head. See *Phrenitis.*

Cephalono′sus. (From κεφαλη, the head, and νοσος, a disease.) This term is applied to the febris hungarica, in which the head is principally affected.

Cephalo-pharynge′us. (From κεφαλη, the head, and φαρυγξ, the throat.) A muscle of the pharynx, otherwise named *constrictor pharyngis inferior;* which see.

Cephalopo′nia. (From κεφαλη, the head, and ϖονος, pain.) Head-ache; heaviness of the head.

Cepi′ni. Vinegar.

Cepula. Large myrobalans.

CE′RA. Wax. Bees' wax. A solid concrete substance, collected from vegetables by bees, and extracted from their combs after the honey is got out, by heating and pressing them. With rectified spirit it forms, by the assistance of heat, a gelatinous liquid. It is perfectly insoluble in watery liquors. When melted, it assumes the appearance of oil, and in this state is easily combined with oils and liquid fats. It is very inflammable, and burns totally away. In the state in which it is obtained from the combs, it is called yellow wax, *cera flava*; and this, when new, is of a lively yellow colour, somewhat tough, yet easy to break: by age, it loses its fine colour, and becomes harder and more brittle. Yellow wax, after being reduced into thin cakes, and bleached by a long exposure to the sun and open air, is again melted, and formed into round cakes, called virgin wax, or white wax, *cera alba*. The chief medicinal use of wax, is in plasters, unguents, and other like external applications, partly for giving the requisite consistence to other ingredients, and partly on account of its own emollient quality.

CE′RA A′LBA. See *Cera*.

Ce′ra dica′rdo. The carduus pinea.

CE′RA FLA′VA. Yellow wax. See *Cera*.

Cerǽæ. (From *κερας*, a horn.) So Rufus Ephesius calls the cornua of the uterus.

Cerani′tes. (From *κεραννυμι*, to temper together.) A name formerly applied to a pastil, or troch, by Galen.

Ce′ras. (Κερας, a horn.) A wild sort of parsnep is so named from its shape.

CE′RASA. (Κερασος, the cherry-tree; from Κερασουντη, a town in Pontus, whence Lucullus first brought them to Rome; or from *κηρ*, the heart; from the fruit having a resemblance to it in shape and colour.) The cherry. See *Prúnus*.

Ce′rasa nigra. Black cherries. The fruit of the *Prunus Avium*, which see.

Ce′rasa ru′bra, sati′va, or a′nglica. Red cherries. See *Prunus Cerasus*.

Cerasia′tum. (From *cerasus*, a cherry.) A purging medicine in Libavius; so called because the juice of cherries is an ingredient.

Cera′sius. *Crasios*. (From *cerasus*, a cherry.) The name of two ointments in Mesue.

Cera′sma. (From *κεραννυμι*, to mix.) A mixture of cold and warm water, when the warm is poured into the cold.

Ce′rasus. The cherry-tree. See *Cerasa* and *Prunus*.

CE′RATE. (From *cera*, wax.) *Ceratum*. A composition of wax, oil, or lard, with or without other ingredients. The obsolete synonyms are, *cerelæum*, *ceroma*, *ceronium*, *cerotum*, *ceratomalagma*. Cerates take their name from the wax which enters into their composition, and to which they owe their consistence, which is intermediate between that of plasters and that of ointments; though no very definite rule for this consistence is, in fact, either given or observed.

Cera′tia. (From *κερας*, a horn, which its fruit is supposed to resemble.) The siliqua dulcis. See *Ceratonica*.

Cera′tia diphy′llus. See *Courbaril*.

Cerato-glo′ssus. (From *κερας*, a horn, and *γλωσσα*, a tongue.) A muscle, so named from its shape and insertion into the tongue. See *Hyoglossus*.

Cerato-hyoide′us. (From the *os hyoides*.) See *Stylo-hyoideus*.

Ceratoi′des. (From *κερaτος*, the genitive of *κερας*, horn, and *ειδος*, appearance.) See *Cornea*.

Cerato-mala′gma. A cerate.

Cerato′nia si′liqua. The systematic name of the plant which affords the sweet pod. *Ceratium*. *Ceratia*. *Siliqua dulcis*. The pods are about four inches in length, and as thick as one's finger, compressed and unequal, and mostly bent; they contain a sweet brown pulp, which is given in the form of decoction, as a pectoral in asthmatic complaints and coughs.

CERA′TUM. See *Cerate*, and *Ceratum simplex*.

Cera′tum a′lbum. See *Ceratum cetacei*.

Cera′tum calome′lanos. ℞. Calom. ʒj. Cerat. calam. ℥ss. Misce. Some practitioners are partial to this as a dressing for chancres.

Cera′tum calami′næ. Formerly called *ceratum lapidis calaminaris*, and *ceratum epuloticum*. Calamine cerate. Take of prepared calamine, yellow wax, of each half a pound; olive oil, a pint. Mix the oil with the melted wax; then remove it from the fire, and, as soon as it begins to thicken, add the calamine, and stir it constantly, until the mixture becomes cold. A composition of this kind was first introduced under the name of Turner's cerate. It is well calculated to promote the cicatrization of ulcers.

Cera′tum ceta′cei. *Ceratum spermatis ceti*. *Ceratum album*. Spermaceti cerate. Take of spermaceti, half an ounce; white wax, two ounces; olive oil, 4 fluid-ounces. Add the oil to the spermaceti and wax, previously melted together, and stir them until the mixture becomes cold. This cerate is cooling and emollient, and applied to excoriations, &c.: it may be used with advantage in all ulcers, where no stimulating substance can be applied, being extremely mild and unctuous.

Cera′tum coni′i. Hemlock cerate. ℞. unguenti conii ℔j. Spermatis ceti ℥jj. Ceræ albæ ℥iii. Misce. One of the formulæ of St. Bartholomew's hospital, occasionally applied to cancerous, scrophulous, phagedenic, herpetic, and other inveterate sores.

Cera′tum ci′trinum. See *Ceratum resinæ*.

Cera′tum epulo′ticum. See *Ceratum calaminæ*.

Cera′tum la′pidis calamina′ris. See *Ceratum calaminæ*.

Cera'tum litha'rgyri aceta'ti compo'situm. See *Ceratum plumbi compositum*.

Cera'tum ly'ttæ. *Ceratum cantharidis*. Cerate of blistering fly. Take of spermaceti cerate, six drachms; blistering flies, in very fine powder, a drachm. Having softened the cerate by heat, add the flies, and mix them together.

Cera'tum plu'mbi superaceta'tis. *Unguentum cerussæ acetatæ*. Cerate of superacetate of lead. Take of superacetate of lead, powdered, two drachms; white wax, two ounces; olive oil, half a pint. Dissolve the wax in seven fluid-ounces of oil; then gradually add thereto the superacetate of lead, separately rubbed down with the remaining oil, and stir the mixture with a wooden slice, until the whole has united. This cerate is cooling and desiccative.

Cera'tum plu'mbi compo'situm. *Ceratum lithargyri acetati compositum*. Compound cerate of lead. Take of solution of subacetate of lead, two fluid-ounces and a half; yellow wax, four ounces; olive oil, nine fluid-ounces; camphor, half a drachm. Mix the wax previously melted, with eight fluid-ounces of oil; then remove it from the fire, and, when it begins to thicken, add gradually the solution of subacetate of lead, and constantly stir the mixture with a wooden slice, until it gets cold. Lastly, mix in the camphor, previously dissolved in the remainder of the oil. Its virtues are cooling, desiccative, resolvent against chronic rheumatism, &c. &c.; and as a proper application to superficial ulcers, which are inflamed.

Cera'tum resi'næ. *Ceratum resinæ flavæ. Ceratum citrinum*. Resin cerate. Take of yellow resin, yellow wax, of each a pound; olive oil, a pint. Melt the resin and wax together, over a slow fire; then add the oil, and strain the cerate, while hot, through a linen cloth. Digestive.

Cera'tum sabi'næ. Savine cerate. Take of fresh leaves of savine, bruised, a pound; yellow wax, half a pound; prepared lard, two pounds. Having melted together the wax and lard, boil therein the savine leaves and strain through a linen cloth. This article is of late introduction, for the purpose of keeping up a discharge from blistered surfaces. It was first described by Mr. Crowther, and has since been received into extensive use, because it does not produce the inconveniences that follow the constant application of the common blistering cerate. A thick white layer forms daily upon the part, which requires to be removed, that the cerate may be applied immediately to the surface from which the discharge is to be made.

Cera'tum sapo'nis. Soap cerate. Take of hard soap, eight ounces; yellow wax, ten ounces; semi-vitreous oxide of lead, powdered, a pound; olive oil, a pint; vinegar, a gallon. Boil the vinegar, with the oxide of lead, over a slow fire, constantly stirring, until the union is complete; then add the soap, and boil it again in a similar manner, until the moisture is entirely evaporated; then mix in the wax, previously melted with the oil. Resolvent; against scrophulous tumours, &c. It is a convenient application in fractures, and may be used as an external dressing for ulcers.

Cera'tum si'mplex. *Ceratum*. Simple cerate. Take of olive oil, four fluid-ounces; yellow wax, four ounces; having melted the wax, mix the oil with it.

Cera'tum spe'rmatis ce'ti. See *Ceratum cetacei*.

Ce'rberus. (Κερβερος.) A fanciful name given to the compound powder of scammony, because, like the dog Cerberus, it has three heads, or principal ingredients, each of which is eminently active.

Cerchna'leum. (From *κερχω*, to make a noise.) A wheezing, or bubbling noise, made by the trachea, in breathing.

Ce'rchnos. (From *κερχω*, to wheeze.) Wheezing.

Cerchno'des. (From *κερχω*, to wheeze.) One who labours under a dense breathing, accompanied with a wheezing noise.

Cercho'des. The same as cerchnodes.

Ce'rcis. (*κερκις*, from *κρεκω*, to shriek.) This word literally means the spoke of a wheel, and has its name from the noise which wheels often make. In anatomy it means the radius, a bone supposed to be like a spoke. Also a pestle, from its shape.

CERCO'SIS. (From *κερκος*, a tail.) A polypus of the uterus. It is sometimes applied to an enlargement of the clitoris.

Ce'rea. (From *cera*, wax.) The cerumen aurium, or wax of the ear.

Cerea'lia. (Solemn feasts to the goddess Ceres.) All sorts of corn, of which bread or any nutritious substance is made, come under the head of *cerealia*, which term is applied by bromatologists as a genus.

Cerebe'lla uri'na. Paracelsus thus distinguishes urine which is whitish, of the colour of the brain, and from which he pretended to judge of some of its distempers.

CEREBE'LLUM. (Dim. of *cerebrum*.) The little brain. A somewhat round viscus, of the same use as the brain; composed, like the brain, of a cortical and medullary substance, divided by a septum into a right and left lobe, and situated under the tentorium, in the inferior occipital fossæ. In the cerebellum are to be observed the *crura cerebelli*, the fourth ventricle, the *valvula magna cerebri*, and the *protuberantiæ vermiformes*.

CE'REBRUM. (*Quasi carebrum*; from *καρα*, the head.) The brain. A large round viscus, divided superiorly into a *right* and *left hemisphere*, and inferiorly into *six lobes*, two anterior, two middle, and two posterior; situated within the cranium, and surrounded by the dura and pia mater, and tunica arachnoides. It is composed of a *cortical sub-*

stance, which is external; and a *medullary*, which is internal. It has three *cavities*, called *ventricles*; two anterior, or lateral, which are divided from each other by the *septum lucidum*, and in each of which is the *choroid plexus*, formed of blood-vessels; the third ventricle is a space between the thalami nervorum opticorum. The principal prominences of the brain are, the *corpus callosum*, a medullary eminence, conspicuous upon laying aside the hemispheres of the brain; the *corpora striata*, two striated protuberances, one in the anterior part of each lateral ventricle; the *thalami nervorum opticorum*, two whitish eminences behind the former, which terminate in the optic nerves; the *corpora quadrigemina*, four medullary projections called by the antients, *nates* and *testes*; a little cerebrine tubercle lying upon the nates, called the *pineal gland*; and lastly, the *crura cerebri*, two medullary columns which proceed from the basis of the brain to the *medulla oblongata*. The cerebral arteries are branches of the carotid and vertebral arteries. The veins terminate in *sinusses*, which return their blood into the internal jugulars. The use of the brain is to give off nine pairs of nerves, and the spinal marrow, from which thirty-one more pairs proceed, through whose means the various senses are performed, and muscular motion excited. It is also considered as the organ of the intellectual functions.

Ce′rebrum elonga′tum. The medulla oblongata.

Cerefo′lium. A corruption of chærophyllum. See *Scandix*.

Cerefo′lium hispa′nicum. The plant called by us Sweet-cicely.

Cerefo′lium sylve′stre. See *Chærophyllum*.

Ce′rei medica′ti. See *Bougie*.

Cerelæ′um. (From κηρος, wax, and ελαιον, oil.) A cerate, or liniment, composed of wax and oil. Also the oil of tar.

Cerevi′siæ ferme′ntum. Yeast.

CEREVI′SIA. (From *ceres*, corn, of which it is made.) Ale. Beer. Any liquor made from corn.

Cerevi′siæ catapla′sma. Into the grounds of strong beer, stir as much oatmeal as will make it of a suitable consistence. This is sometimes employed as a stimulant and antiseptic to mortified parts.

Ce′ria. (From *cereus*, soft, pliant.) *Ceriæ*. The flat worms which breed in the intestines.

Ce′rion. (From κηριον, a honey-comb.) A kind of achor.

Cero′ma. (From κηρος, wax.) *Ceronium*. Terms used by the antient physicians for an unguent, or cerate, though originally applied to a particular composition which the wrestlers used in their exercises.

Ceropi′ssus. (From κηρος, wax, and ϖισσα, pitch.) A plaster composed of pitch and wax.

Cero′tum. (Κερωτον.) A cerate.

CERU′MEN AU′RIUM. (*Cerumen*; dim. of *cera*, wax.) *Cerea. Aurium sordes. Marmorata aurium. Cypsele. Cypselis. Fugile.* The waxy secretion of the ears, situated in the meatus auditorius externus.

CERU′SSA. (Arab.) Cerusse, or *white lead*. See *Plumbi subcarbonas*.

Ceru′ssa aceta′ta. See *Plumbi superacetas*.

Ce′rvi spi′na. See *Rhamnus catharticus*.

CERVI′CAL. (*Cervicalis*; from *cervix*, the neck.) Belonging to the neck; as cervical nerves, cervical muscles, &c.

Cervi′cal a′rteries. *Arteriæ cervicales*. Branches of the subclavians.

Cervi′cal ve′rtebræ. The seven uppermost of the vertebræ, which form the spine. See *Vertebræ*.

Cervica′ria. (From *cervix*, the neck; so named because it was supposed to be efficacious in disorders and ailments of the throat and neck.) The herb throat-wort.

CE′RVIX. (*-vicis*, f. quasi *cerebri via*; as being the channel of the spinal marrow.) The neck. That part of the body which is between the head and shoulders. The cervix uteri is the neck of the uterus; or that part of it which is immediately above or beyond the os tincæ. This term is also applied to other parts, as cervix vesicæ, ossis, &c.

Cestri′tes. (From κεϛρον, betony.) Wine impregnated with betony.

Ce′strum. (From κεϛρα, a dart; so called from the shape of its flowers, which resemble a dart; or because it was used to extract the broken ends of darts from wounds.) The herb betony.

CETA′CEUM. See *Physeter*.

CE′TERACH. (Blanchard says this word is corrupted from *Pteryga*, ϖτηρυξ, q. v. as peteryga, ceteryga, and ceterach.) *Scolopendria vera. Dorodilla?* Spleenwort. Miltwaste. This small bushy plant, *Asplenium ceterach; frondibus pinnatifidis, lobis alternis confluentibus obtusis* of Linnæus, grows upon old walls and rocks. It has an herbaceous, mucilaginous, roughish taste, and is recommended as a pectoral. In Spain it is given, with great success, in nephritic and calculous diseases.

Cevadi′lla. (Dim. of *ceveda*, barley. Spanish.) *Cevadilla Hispanorum. Sevadilla. Sabadilla. Hordeum causticum. Canis interfector.* Indian caustic barley. The plant whose seeds are thus denominated, is a species of *veratrum*: they are powerfully caustic, and are administered with very great success as a vermifuge. They are also diuretic and emetic. The dose to a child, from two to four years old, is two grains; from hence to eight, five grains; from eight to twelve, ten grains.

Ceyenne pepper. See *Capsicum*.

Cha′a. A Chinese name for tea.

Chacari′llæ co′rtex. See *Croton Cascarilla.*

Chærofo′lium. See *Scandix.*

CHÆROPHY′LLUM. (Χαιροφυλλον: from χαιρω, to rejoice, and φυλλον, a leaf; so called from the abundance of its leaves.) Chervil.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.*

2. The pharmacopœial name of some plants. See *Scandix,* and *Chærophyllum sylvestre.*

Chærophy′llum sylve′stre. *Cicutaria.* Bastard hemlock. This plant, *Chærophyllum sylvestre; caule lævi striato; geniculis tumidiusculis,* of Linnæus, is often mistaken for the true hemlock. It may with great propriety be banished from the list of officinals, as it possesses no remarkable property.

Chæ′ta. (From χεω, to be diffused.) The human hair.

Chala′sis. (From χαλαω, to relax.) Relaxation.

Chala′stica. (From χαλαω, to relax.) Medicines which relax.

Chala′zion. (From χαλαζα, a hail-stone.) *Chalaza. Chalazium. Grando.* An indolent, moveable tubercle on the margin of the eyelid, like a hail-stone. A species of hordeolum. It is that well-known affection of the eye, called a stye, or stian. It is white, hard, and encysted, and differs from the *crithe,* another species, only in being moveable. Writers mention a division of Chalazion into scirrhous, cancerous, cystic, and earthy.

Cha′lbane. (Καλβανη.) Galbanum.

Chalca′nthum. (From χαλκος, brass, and ανθος, a flower.) Vitriol; or rather, vitriol calcined red. The flowers of brass.

Chalcei′on. A species of pimpinella.

Chalcoi′deum os. The os cuneiforme of the tarsus.

Chalk. See *Creta.*

Chalk-stones. A name given to the concretions in the hands and feet of people violently afflicted with the gout, from their resembling chalk, though chemically different.

Chali′cratum. (From χαλις, an old word that signifies pure wine, and κεραννυμι, to mix.) Wine mixed with water.

Chali′nos. *Chalinus.* That part of the cheeks, which, on each side, is contiguous to the angles of the mouth.

CHALY′BEATE. (*Chalybeata,* sc. *medicamenta;* from *chalybs,* iron, or steel.) Of or belonging to iron. A term given to any medicine into which iron enters; as chalybeate mixture, pills, waters, &c.

CHALY′BEATE WA′TERS. Any mineral water which abounds with iron; such as the waters of Tunbridge, Spa, Pyrmont, Cheltenham, Scarborough, and Hartfel; and many others.

Cha′lybis rubi′go præpara′ta. See *Ferri subcarbonas.*

CHA′LYBS. (From *Chalybes,* a people in Pontus, who dug iron out of the earth.) *Acies.* Steel. The best, hardest, finest, and the closest-grained forged iron. As a medicine, steel differs not from iron.

Cha′lybs tartariza′tus. The ferrum tartarizatum.

Chamæba′lanus. (From χαμαι, on the ground, and βαλανος, a nut.) Wood peas. Earth nuts.

Chamæbu′xus. (From χαμαι, on the ground, and ϖυξος, the box-tree.) The dwarf box-tree.

Chamæce′drus. (From χαμαι, on the ground, and κεδρος, the cedar-tree.) *Chamæcedrys.* A species of dwarf abrotanum.

Chamæci′ssus. (From χαμαι, on the ground, and κισσος, ivy.) Ground-ivy.

Chamæcle′ma. (From χαμαι, on the ground, and κλημα, ivy.) The ground-ivy.

CHAMÆ′DRYS. (From χαμαι, on the ground, and δρυς, the oak; so called from its leaves resembling those of the oak.) See *Teucrium.*

Chamæ′drys inca′na mari′tima. The marum syriacum.

Chamæ′drys frute′scens. A name for teucrium.

Chamæ′drys palu′stris. A name given to scordium.

Chamæ′drys spu′ria. A name given to veronica.

Chamæle′a. (From χαμαι, on the ground, and ελαια, the olive-tree.) See *Daphne alpina.*

Chamælæa′gnus. (From χαμαι, on the ground, and ελαιαγνος, the wild olive.) The myrtus brabantica.

Chamæ′leon. (From χαμαι, on the ground, and λεων, a lion, *i. e.* dwarf lion.) The chamæleon, an animal supposed to be able to change his colour at pleasure. Also the name of many thistles, so named from the variety and uncertainty of their colours.

Chamæ′leon a′lbum. See *Carlina acaulis.*

Chamæ′leon ve′rum. The distaff thistle.

Chamæleu′ce. (From χαμαι, on the ground, and λευκη, the herb colt's-foot.) Tussilago, or colt's-foot.

Chamæli′num. (From χαμαι, on the ground, and λινον, flax.) Linum catharticum, or purging flax.

CHAMÆME′LUM. (From χαμαι, on the ground, and μηλον, an apple; because it grows upon the ground, and has the smell of an apple.) Common Chamomile. See *Anthemis nobilis.*

Chamæme′lum canarie′nse. The *Chrysanthemum frutescens* of Linnæus.

Chamæme′lum chrysa′nthemum. The buphthalmum germanicum.

Chamæme′lum fœ′tidum. The *Anthemis cotula* of Linnæus.

Chamæme′lum flo′re pleno. *Chamæ-*

melum nobile flore multiplici. Double chamomile. A variety of the anthemis nobilis; which see.

Chamæme'lum no'bile. See *Anthemis nobilis.*

Chamæme'lum vulga're. See *Matricaria chamomilla.*

Chamæ'morus. (χαμαιμορεα, from χαμαι, on the ground, and μορεα, the mulberry-tree.) See *Rubus.*

Chamæpeu'ce. (From χάμάι, on the ground, and ϖευκη, the pine-tree.) Camphorata, or stinking ground-pine, formerly said to be antirheumatic.

CHAMÆ'PITYS. (From χαμαι, the ground, and ϖιτυς, the pine-tree.) See *Teucrium.*

Chamæ'pitys moscha'ta. See *Teucrium Iva.*

Chamæ'plion. A name in Oribasius for erysimum, or hedge mustard.

Chamæra'phanum. So Paulus Æginetа calls the upper part of the root of the apium.

Chamæra'phanus. (From χαμαι, on the ground, and ραφανος, the radish.) The upper part of the root of apium, according to P. Ægineta. The smallage, or parsley. Also dwarf radish.

Chamæ'riphes. The palma minor.

Chamærodode'ndron. (From χαμαι, on the ground, and ροδοδενδρον, the rose laurel.) The *Azelæa pontica* of Linnæus.

Chamæ'rubus. (From χαμαι, on the ground, and *rubus,* the bramble.) The chamæmorus.

Chamæspa'rtium. (From χαμαι, on the ground, and σπαρτιον, Spanish broom.) The genista tinctoria.

CHAMBERLEN, Hugh, a native of London, about the middle of the 17th century. He succeeded his father as a practitioner in midwifery, and had also two brothers in the same profession. They invented among them an instrument, the obstetric forceps, which greatly facilitated delivery in many cases, and often saved the child: but to him alone, as most distinguished, the merit has been usually ascribed. In 1683, he published a translation of Mauriceau's Observations, which was much sought after. The instrument procured him great celebrity in this, as well as other countries; and, with successive improvements by Smellie, &c., still continues to be esteemed one of the most valuable adjuvants in the obstetric art. The period of his death is not ascertained.

CHAMBERS. The space between the capsule of the crystalline lens and the cornea of the eye, is divided by the iris into two spaces, called chambers; the space before the iris is termed the anterior chamber; and that behind it, the posterior. They are filled with an aqueous fluid.

Chamomi'lla no'stras. See *Matricaria Chamomilla.*

Chamomi'lla roma'na. See *Anthemis.*

CHA'NCRE. (French. From καρκινος, cancer.) A sore which arises from the direct application of the venereal poison to any part of the body. Of course it mostly occurs on the genitals. Such venereal sores as break out from a general contamination of the system, in consequence of absorption, never have the term chancre applied to them.

Chaoma'ntia si'gna. So Paracelsus calls those prognostics that are taken from observations of the air; and the skill of doing this, the same author calls *Chaomancia.*

Chao'sda. Paracelsus uses this word as an epithet for the plague.

CHAPMAN, Edmund, was born about the end of the 17th century; and, after becoming properly instructed as a surgeon and accoucheur, settled in London, and soon distinguished himself by his success in difficult labours. His plan consisted chiefly in turning the child, and delivering by the feet, when any part but the head presented; also in often availing himself of the forceps of Chamberlen, much improved by himself, and of which he had the merit of first giving an account to the public in his treatise on midwifery, in 1732. He also ably defended the cause of the men-midwives against the attack of Douglas, in a small work, in 1737.

Cha'rabe. (Arab.) A name given to amber; which see.

Cha'radra. (From χαρασσω, to excavate.) The bowels, or sink of the body.

Charamais. Purging hazel-nut.

Chara'ntia. The momordica elaterium.

Chárcoal. See *Carbon.*

Cha'rdone. The Cinara spinosa.

Charistolo'chia. (From χαρις, joy, and λοχια, the flux of women after child-birth; so named from its supposed usefulness to women in childbirth.) The plant mugwort, or artemisia.

CHARLTON, Walter, was born in Somersetshire, 1619. After graduating at Oxford, where he distinguished himself by his learning, he was appointed physician to Charles I., and admitted a fellow of the Royal College of Physicians, in London. He had afterwards the honour of attending Charles II., and was one of the first members of the Royal Society. He was author of several publications, on medical and other subjects; the former of which contained little original matter, but had the merit of spreading the knowledge of the many improvements made about that period, particularly in anatomy and physiology; the principal of them are his "Exercitationes Pathologicæ," and his "Natural History of Nutrition, Life, and voluntary Motion." In 1689, he was chosen president of the College, and held that office two years. He afterwards retired to Jersey, and died in 1707.

Cha′rme. (From χαιρω, to rejoice.) *Charmis.* A cordial antidote mentioned by Galen.

Cha′rpie. (French.) Scraped linen, or lint.

Cha′rta. (Chald.) Paper. The amnios, or interior fœtal membrane, was called the *charta virginea*, from its likeness to a piece of fine paper.

Cha′rtreux, pou′dre de. (So called because it was invented by some friars of the Carthusian order.) A name of the kermes mineral.

Cha′sme. (From χαινω, to gape.) *Chasmus.* Oscitation. Gaping.

Chaste tree. The *Agnus castus.*

Cha′te. The cucumis Ægyptia.

Cheek-bone. See *Jugale os.*

CHEESE. *Caseus.* The coagulum of milk. When prepared from rich milk, and well made, it is very nutritious in small quantities: but mostly indigestible when hard and ill prepared, especially to weak stomachs.

Cheiloca′ce. (From χειλος, a lip, and κακον, an evil.) The lip-evil. A swelling of the lips, or canker in the mouth.

Cheime′lton. (From χειμα, winter.) Chilblains.

CHEIRA′NTHUS. (From χειρ, a hand, and ανθος, a flower; so named from the likeness of its blossoms to the fingers of the hand.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia.* Order, *Siliquosa.* The wall-flower.

Cheira′nthus chei′ri. The systematic name of the wall-flower. *Leucoium luteum. Viola lutea.* Common yellow wall-flower. The flowers of this plant, *Cheiranthus cheiri; foliis lanceolatis, acutis, glabris; ramis angulatis; caule fruticoso,* of Linnæus, are recommended as possessing nervine and deobstruent virtues. They have a moderately strong, pleasant smell, and a nauseous, bitter, somewhat pungent taste.

Cheira′psia. (From χειρ, the hand, and απτομαι, to touch.) The act of scratching; particularly the scratching one hand with another, as in the itch.

Chei′ri. (*Cheiri,* Arab.) See *Cheiranthus.*

Cheiria′ter. (From χειρ, the hand, and ιατρος, a physician.) A surgeon whose office it is to remove maladies by operations of the hand.

Cheiri′sma. (From χειριζομαι, to labour with the hand.) Handling. Also a manual operation.

Cheiri′xis. (From χειριζομαι, to labour with the hand.) The art of surgery.

Cheirono′mia. (From χειρονομεω, to exercise with the hands.) An exercise mentioned by Hippocrates, which consisted of gesticulations with the hands, like our dumb-bells.

Che′la. (χηλη, *forceps;* from χεω, to take.) A forked probe, for drawing a polypus out of the nose. Fissures in the feet, or other places.

Che′læ cancro′rum. See *Cancer.*

Che′lidon. The bend of the arm.

CHELIDO′NIUM. (From χελιδων, the swallow. It is so named from an opinion, that it was pointed out as useful for the eyes by swallows, who are said to open the eyes of their young by it; or because it blossoms about the time when swallows appear.) Celandine. A genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Monogynia.* There is only one species used in medicine, and that rarely.

Chelido′nium ma′jus. *Papaver corniculatum, luteum.* Tetterwort, and great celandine. The herb and root of this plant, *Chelidonium majus; pedunculis umbellatis,* of Linnæus, have a faint, unpleasant smell, and a bitter, acrid, durable taste, which is stronger in the roots than the leaves. They are aperient and diuretic, and recommended in icterus, when not accompanied with inflammatory symptoms. The chelidonium should be administered with caution, as it is liable to irritate the stomach and bowels. Of the dried root, from ʒss to ʒj is a dose; of the fresh root, infused in water, or wine, the dose may be about ℥ss. The decoction of the fresh root is used in dropsy, cachexy, and cutaneous complaints. The fresh juice is used to destroy warts, and films in the eyes; but, for the latter purpose, it is diluted with milk.

Chelido′nium mi′nus. See *Ranunculus ficaria.*

Chelo′ne. (χελωνη.) The tortoise. An instrument for extending a limb, and so called because, in its slow motions, it represents a tortoise. This instrument is mentioned in Oribasius.

Chelo′nion. (From χελωνη, the tortoise; so called from its resemblance to the shell of a tortoise.) A hump, or gibbosity in the back.

CHELTENHAM WATER. One of the most celebrated purging waters in England, and the reputation of it is daily increasing, as it possesses both a saline and chalybeate principle. When first drawn, it is clear and colourless, but somewhat brisk; has a saline, bitterish, chalybeate taste. It does not keep, nor bear transporting to any distance; the chalybeate part being lost by precipitation of the iron, and in the open air it even turns fœtid. The salts, however, remain. Its heat, in summer, was from 50° to 55° or 59°, when the medium heat of the atmosphere was nearly 15° higher. On evaporation, it is found to contain a calcareous earth, mixed with ochre and a purging salt. A general survey of the component parts of this water, according to a variety of analyses, shows that it is decidedly saline, and contains much more salt than most mineral waters. By far the greater part of the salts are of a purgative kind, and therefore an action on the bowels is a constant effect, notwithstanding the considerable quantity of selenite and earthy carbonates which may be supposed to have a contrary tendency. Cheltenham water is, besides, one of the strongest chalybeates we are acquainted with. The iron is suspended entirely by the carbonic acid, of which gas the water contains about an eighth of its bulk; but, from the abundance of earthy carbonates, and oxide of iron, not much of it is uncombined. It has, besides, a slight impregnation of sulphur, but so little as to be scarcely appreciable, except by very delicate tests. The sensible effects produced by this water, are generally, on first taking it, a degree of drowsiness, and sometimes head-ache, but which soon go off spontaneously, even previous to the operation on the bowels. A moderate dose acts powerfully, and speedily, as a cathartic, without occasioning griping, or leaving that faintness and languor which often follow the action of the rougher cathartics. It is principally on this account, but partly too from the salutary operation of the chalybeate, and perhaps the carbonic acid, that the Cheltenham water may be, in most cases, persevered in, for a considerable length of time, uninterruptedly, without producing any inconvenience to the body; and during its use, the appetite will be improved, the digestive organs strengthened, and the whole constitution invigorated. A dose of this water, too small to operate directly on the bowels, will generally determine pretty powerfully to the kidneys. As a purge, this water is drank from one to three pints; in general, from half a pint to a quart is sufficient. Half a pint will contain half a drachm of neutral purging salts, four grains of earthy carbonates, and selenite, about one-third of a grain of oxide of iron; together with an ounce in bulk of carbonic acid, and half an ounce of common air, with a little sulphuretted hydrogen. Cheltenham water is used, with considerable benefit, in a number of diseases, especially of the chronic kind, and particularly those called bilious: hence it has been found of essential service in the cure of glandular obstructions, and especially those that affect the liver, and the other organs connected with the functions of the alimentary canal. Persons who have injured their biliary organs, by a long residence in hot climates, and who are suffering under the symptoms, either of excess of bile or deficiency of bile, and an irregularity in its secretion, receive remarkable benefit from a course of this water, judiciously exhibited. Its use may be here continued, even during a considerable degree of debility; and from the great determination to the bowels it may be employed with advantage to check the incipient symptoms of dropsy, and general anasarca, which so often proceed from an obstruction of the liver. In scrophulous affections, the sea has the decided preference; in painful affections of the skin. called scorbutic eruptions, which make their appearance at stated intervals, producing a copious discharge of lymph, and an abundant desquamation, in common with other saline purgative springs, this is found to bring relief; but it requires to be persevered in for a considerable time, keeping up a constant determination to the bowels, and making use of warm bathing. The season for drinking the Cheltenham water is during the whole of the summer months.

Che′lys. (χελυς, a shell.) The breast is so called, as resembling, in shape and office, the shell of some fishes.

Chely′scion. (From χελυς, the breast.) A dry, short cough, in which the muscles of the breast are very sore.

Che′ma. A measure mentioned by the Greek physicians, supposed to contain two small spoonfuls.

Che′mia. Chemistry; which see.

Che′mical appara′tus. A general expression, denoting the instruments, vessels, machinery, furniture, and utensils of a laboratory.

CHEMISTRY. (χυμια, and sometimes χημια: *chamia*, from *chama*, to burn, Arab. this science being the examination of all substances by fire.) *Chemia. Chimia. Chymia.* The learned are not yet agreed as to the most proper definition of chemistry. Boerhaave seems to have ranked it among the arts. According to Macquer, it is a science, whose object is to discover the nature and properties of all bodies by their analyses and combinations. Dr. Black says, it is a science which teaches, by experiments, the effects of heat and mixture on bodies; and Fourcroy defines it a science which teaches the mutual actions of all natural bodies on each other. "Chemistry," says Jacquin, "is that branch of natural philosophy which unfolds the nature of all material bodies, determines the number and properties of their component parts, and teaches us how those parts are united, and by what means they may be separated and recombined." Mr. Heron defines it, "That science which investigates and explains the laws of that attraction which takes place between the minute component particles of natural bodies." The objects to which the attention of chemists is directed, comprehend the whole of the substances that compose the globe.

CHEMO′SIS. (From χαινω, to gape; because it gives the appearance of a gap, or aperture.) Inflammation of the conjunctive membrane of the eye, in which the white of the eye is distended with blood, and elevated above the margin of the transparent cornea. In Cullen's Nosology, it is a variety of the ophthalmia membranarum, or an inflammation of the membranes of the eye.

Chenopodio-mo'rus. (From *chenopodium* and *morus*, the mulberry; so called because it is a sort of chenopodium, with leaves like a mulberry.) The herb mulberry-blight, or strawberry-spinach.

CHENOPO'DIUM. (From χην, a goose, and πους, a foot; so called from its supposed resemblance to a goose's foot.) The herb chenopody, goose's foot. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.*

Chenopo'dium ambrosioi'des. The systematic name of the Mexican tea-plant. *Botrys Mexicana. Botrys ambrosioides Mexicana. Chenopodium Mexicanum. Botrys Americana.* Mexico tea. Spanish tea and Artemisian botrys. A decoction of this plant, *Chenopodium ambrosioides; foliis lanceolatis dentatis, racemis foliatis simplicibus,* of Linnæus, is recommended in paralytic cases. Formerly the infusion was drunk instead of Chinese tea.

Chenopo'dium anthelmi'nticum. The seeds of this plant, *Chenopodium anthelminthum; foliis ovato-oblongis dentatis, racemis aphyllis,* of Linnæus, though in great esteem in America for the cure of worms, are never exhibited in this country. They are powdered and made into an electuary, with any proper syrup, or conserve.

Chenopo'dium Bo'trys. The systematic name of the Jerusalem oak. *Botrys vulgaris. Botrys. Ambrosia. Artemisia chenopodium. Atriplex odorata. Atriplex suaveolens.* Jerusalem oak. This plant, *Chenopodium botrys; foliis oblongis sinuatis, racemis nudis multifidis,* of Linnæus, was formerly administered in form of decoction in some diseases of the chest; as humoral asthma, coughs, and catarrhs. It is now fallen into disuse.

Chenopo'dium bo'nus Henri'cus. The systematic name of the English mercury. *Bonus Henricus. Tota bona. Lapathum unctuosum. Chenopodium.* English mercury. The plant to which these names are given in the pharmacopœias, is the *Chenopodium bonus Henricus; foliis triangulari-sagittatis, integerrimis, spicis compositis aphyllis axillaribus,* of Linnæus. It is a native of this country, and common in waste grounds from June to August. The young plant differs little from spinach when cultivated; and in many places the young shoots are eaten in spring like asparagus. The leaves of this plant are accounted emollient, and in this intention have been made an ingredient in decoctions for glysters. They are applied by the common people to flesh wounds and sores under the notion of drawing and healing.

Chenopo'dium fœ'tidum. See *Chenopodium vulvaria.*

Chenopo'dium vulva'ria. The systematic name for the stinking orach. *Atriplex fœtida. Atriplex olida. Vulvaria. Garosmum. Raphex. Chenopodium fœtidum. Blitum fœtidum.* Stinking orach. The very fetid smell of this plant, *Chenopodium; foliis integerrimis rhombeo-ovatis, floribus conglomeratis axillaribus,* of Linnæus, induced physicians to exhibit it in hysterical diseases. It is now superseded by more active preparations.

Che'ras. (From χεω, to pour out.) The struma, or scrophula.

Cherefo'lium. See *Scandix cerefolium.*

Che'rmes. (Arab.) A small berry, full of insects like worms: the juice of which was formerly made into a confection, called confectio alkermes, which has been long disused. Also the worm itself.

Che'rmes minera'lis. Hydro-sulphuret of antimony.

Cherni'bium. *Chernibion.* In Hippocrates it signifies an urinal.

Chero'nia. (From Χειρων, the Centaur.) See *Chironia centaurium.*

Cherry. See *Cerasa nigra* and *Cerasa rubra.*

Cherry, bay. The *Lauro-cerasus.*

Cherry-laurel. The *Lauro-cerasus.*

Cherry, winter. The *Alkekengi.*

Chervi'llum. See *Scandix cerefolium.*

CHESELDEN, William, was born in Leicestershire, 1688. After serving his apprenticeship to a surgeon at Leicester, he came to study at St. Thomas's hospital, to which he afterwards became surgeon. He began to give lectures at the early age of 22, and about the same period was elected Fellow of the Royal Society. Two years after, he published his "Anatomical Description of the Human Body," with some select cases in surgery, which passed through several editions; in one of which he detailed his success in the operation of lithotomy by the lateral method, as it is termed, which he found not so liable to failure as the high operation. He also gave in the Philosophical Transactions, an interesting account of a grown person whom he restored to sight after being blind from infancy; and furnished some other contributions to the same work. Besides being honourably distinguished by some of the French societies, he was appointed principal surgeon to Queen Caroline, to whom he dedicated his splendid work on the bones in 1733. He was four years after chosen surgeon to Chelsea Hospital, and retired from public practice, and lived to the age of 64.

Chesnut, horse. See *Æsculus Hippocastanum.*

Cheu'sis. (From χεω, to pour out.) Liquation. Infusion.

Cheva'stre. A double-headed roller, applied by its middle below the chin; then running on each side, it is crossed on the top of the head; then passing to the nape of the neck, is there crossed: it then passes under the chin, where crossing, it is carried to the top of the head, &c. until it is all taken up.

CHEYNE, George, was born in Scotland, 1670. After graduating in medicine, he came to London, at the age of 30, and published a Theory of Fevers, and five years after a work on Fluxions, which procured his election into the Royal Society; and this was soon followed by his "Philosophical Principles of Natural Religion." Being naturally inclined to corpulency, and indulging in free living, he became, when only of a middle age, perfectly unwieldy, with other marks of an impaired constitution; against which, finding medicines of little avail, he determined to abstain from all fermented liquors, and confine himself to a milk and vegetable diet. This plan speedily relieved the more distressing symptoms, which led him after a while to resume his luxuries; but finding his complaints presently returning, he resorted again to the abstemious plan; by a steady perseverance in which he retained a tolerable share of health to the advanced age of 72. In 1722, in a treatise on the gout, &c. he first inculcated this plan; and two years after greatly enlarged on the same subject, in his celebrated "Essay on Health and Long Life." His "English Malady, or Treatise on Nervous Diseases," which he regarded as especially prevalent in this country, a very popular work, published 1733, contains a candid and judicious narrative of his own case.

Chezana'nce. (From χεζω, to go to stool, and αναγκη, necessity.) It signifies any thing that creates a necessity to go to stool; but, in P. Ægineta, it is the name of an ointment, with which the anus is to be rubbed, for promoting stools.

Chi'a. (From Χιος, an island where they were formerly propagated.) A sweet fig of the island of Chio, or Scio. Also an earth from that island, formerly used in fevers.

Chi'acus. (From Χιος, the island of Scio.) An epithet of a collyrium, whose chief ingredient was wine of Chios.

Chi'adus. In Paracelsus it signifies the same as furunculus.

Chian pepper. See *Capsicum.*

Chian turpentine. See *Pistacia Terebinthus.*

Chia'smus. (From χιαζω, to form like the letter X, chi.) The name of a bandage, whose shape is like the Greek letter X, *chi.*

Chia'stos. The name of a crucial bandage in Oribasius; so called from its resembling the letter X, *chi.*

Chia'stre. The name of a bandage for the temporal artery. It is a double-headed roller, the middle of which is applied to the side of the head, opposite to that in which the artery is opened, and, when brought round to the part affected, it is crossed upon the compress that is laid upon the wound, and then, the continuation is over the coronal suture, and under the chin; then crossing on the compress, the course is, as at the first, round the head, &c. till the whole roller is taken up.

Chi'bou. A spurious species of gum-elemi, spoken of by the faculty of Paris, but not known in England.

Chi'bur. Sulphur.

Chichi'na. Contracted from China chinæ. See *Cinchona.*

Chi'chos. *Chirces.* The affectio bovina, or distemper of black cattle.

Chicken pox. See *Varicella.*

Chickweed. See *Alsine media.*

CHICOYNEAU, Francis, was born at Montpelier in 1672, the second son of a professor there, who becoming blind, he was appointed to discharge his duties, after taking his degrees in medicine. Having acquitted himself very creditably, he was deputed with other physicians to Marseilles in 1720, to devise measures for arresting the progress of the plague, which in the end almost depopulated that city. The zeal which he evinced on that occasion was rewarded by a pension; and on the death of his father-in-law, M. Chirac, in 1731, he was appointed to succeed him as first physician to the king; and received also other honours previously to his death in 1752. He published in 1721, in conjunction with the other physicians, an account of the plague at Marseilles, in which the opinion is advanced, that the disease was not contagious: and having received orders from the king to collect all the observations that had been made concerning that disease, he drew up an enlarged treatise with much candour, and containing a number of useful facts, which was made public in 1744.

CHI'LBLAIN. *Pernio.* An inflammation of the extreme parts of the body, from the application of cold; attended with a violent itching, and soon forming a gangrenous ulcer.

Chi'li, ba'lsamum de. Salmon speaks, but without any proof, of its being brought from Chili. The Barbadoes tar, in which are mixed a few drops of the oil of aniseed, is usually sold for it.

Chiliody'namon. (From χιλιοι, a thousand, and δυναμις, virtue.) An epithet of the herb *Polemonium.* In Dioscorides, this name is given on account of its many virtues.

Chi'lon. (Χειλων.) An inflamed and swelled lip.

Chilpela'gua. A variety of capsicum.

Chitter pin. A species of capsicum.

Chime'thlon. A chilblain.

Chi'mia. See *Chemistry.*

Chimia'ter. (From χυμια, chemistry, and ιατρος, a physician.) A physician who makes the science of chemistry subservient to the purposes of medicine.

Chimo'lea la'xa. Paracelsus means, by this word, the sublimed powder which is separated from the flowers of saline ores.

CHI'NA. (So named from the country of China, from whence it was brought.) See *Smilax China.*

Chi'na chi'næ. A name given to the Peruvian bark.

Chi'na occidenta'lis. *China spuria nodosa. Smilax pseudo-China. Smilax Indica spinosa.* American or West-Indian China. This root is chiefly brought from Jamaica, in large round pieces, full of knots. In scrophulous disorders, it has been preferred to the oriental kind. In other cases it is of similar but inferior virtue.

Chi'na suppo'sita. See *Senecio.*

Chinchi'na. See *Cinchona.*

Chinchi'na Caribæ'a. See *Cinchona Caribæa.*

Chinchi'na de Sa'nta Fe. There are several species of bark sent from Santa Fé; but neither their particular natures, nor the trees which afford them, are yet accurately determined.

Chinchi'na Jamaice'nsis. See *Cinchona Caribæa.*

Chinchi'na ru'bra. See *Cinchona oblongifolia.*

Chinchi'na de St. Lu'cia. St. Lucia bark. See *Cinchona floribunda.*

Chincough. See *Pertussis.*

Chine'nse. The aurantium sinense, or Chinese orange.

Chinese smilax. See *Smilax China.*

Chi'o turpentine. See *Pistacia Terebinthus.*

Chi'oli. In Paracelsus it is synonymous with furunculus.

Chi'ques. A name for the worms which get into the toes of the negroes, and which are destroyed by the oil which flows out of the cashew nut-shell.

CHIRA'GRA. (From χειρ, the hand, and αγρα, a seizure.) The gout in the joints of the hand. See *Arthritis.*

Chiro'nes. (From χειρ, the hand.) Small pustules on the hand and feet, inclosed in which is a troublesome worm.

CHIRO'NIA. (From *Chiron*, the Centaur, who discovered its use.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

2. (From χειρ, the hand.) An affection of the hand, where it is troubled with chirones.

Chiro'nia Centau'rium. *Centaurium minus vulgare. Centaurium parvum. Centaurium minus.* Centaury. *Chironia; corollis quinquefidis infundibuliformibus, caule dichotomo, pistillo simplici,* of Linnæus. This plant is justly esteemed to be the most efficacious bitter of all the medicinal plants indigenous to this country It has been recommended, by Cullen, as a substitute for gentian, and by several is thought to be a more useful medicine. The tops of the centaury plant are directed for use by the colleges of London and Edinburgh, and are most commonly given in infusion; but they may also be taken in powder, or prepared into an extract.

Chiro'nium. (From Χειρων, the Centaur, who is said to have been the first who healed them.) A malignant ulcer, callous on its edges, and difficult to cure.

Chirothe'ca. (From χειρ, the hand, and τιθημι, to put.) A glove of the scarfskin, with the nails, which is brought off from the dead subject, after the cuticle is loosened by putrefaction, from the parts under it.

CHIRU'RGIA. (From χειρ, the hand, and εργον, a work; because surgical operations are performed by the hand.) Chirurgery, or surgery.

Chi'ton. (Χιτων.) A coat, or membrane.

Chi'um. (From Χιος, the island where it was produced.) An epithet of a wine made at Scio.

Chlia'sma. (From χλιαινω, to make warm.) A warm fomentation, called also thermasma.

Chlora'sma. (From χλωρος, green.) Chlorosis, which see.

Chlo'rine. See *Oxymuriatic acid.*

CHLORO'SIS. (From χλωρος, green, pale; from the yellow-greenish look those have who are affected with it.) *Febris alba. Febris amatoria. Icterus albus.* The green sickness. A genus of disease in the class *cachexiæ*, and order *impetigines* of Cullen. It is a disease which affects young females who labour under a retention or suppression of the menses. Heaviness, listlessness to motion, fatigue on the least exercise, palpitations of the heart, pains in the back, loins, and hips, flatulency and acidities in the stomach and bowels, a preternatural appetite for chalk, lime, and various other absorbents, together with many dyspeptic symptoms, usually attend on this disease. As it advances in its progress, the face becomes pale, or assumes a yellowish hue; the whole body is flaccid, and likewise pale; the feet are affected with œdematous swellings; the breathing is much hurried by any considerable exertion of the body; the pulse is quick, but small; and the person is apt to be affected with many of the symptoms of hysteria. To procure a flow of the menses, proves in some cases a very difficult matter; and where the disease has been of long standing, various morbid affections of the viscera are often brought on, which at length prove fatal. Dissections of those who have died of chlorosis, have usually shewn the ovaria to be in a scirrhous, or dropsical state. In some cases, the liver, spleen, and mesenteric glands, have likewise been found in a diseased state.

The cure is to be attempted by increasing the tone of the system, and exciting the action of the uterine vessels. The first may be effected by a generous nutritive diet, with the moderate use of wine; by gentle and daily exercise, particularly on horse-back; by agreeable company, to amuse and quiet the mind; and by tonic medicines, especially the preparations of iron, joined with myrrh, &c. Bathing will likewise help much to strengthen them, if the temperature of the bath be made gradually lower, as the patient bears it; and sometimes drinking the mineral chalybeate waters may assist. The bowels must be kept regular, and occasionally a gentle emetic will prepare for the tonic plan. The other object of stimulating the uterine vessels may be attained by the exercises of walking and dancing; by frequent friction of the lower extremities; by the pediluvium, hip-bath, &c.; by electric shocks, passed through the region of the uterus; by active purgatives, especially those formulæ containing aloes, which acts particularly on the rectum. These means may be resorted to with more probability of success, when there appear efforts of the system to produce the discharge, the general health having been previously improved. Various remedies have been dignified with the title of emmenagogues, though mostly little to be depended on, as madder, &c. In obstinate cases, the tinctura lyttæ, or savine, may be tried, but with proper caution, as the most likely to avail.

Chnus. (From χναυω, to grind, or rasp.) Chaff. Bran. Also fine wool, or lint, which is, as it were, rasped from lint.

Choke damp. The name given by miners to a noxious air, occasionally found in the bottom of mines and pits. It is heavier than common air, therefore lies chiefly at the bottom of the pits; it extinguishes flame, and is noxious to animals. It is probably carbonic acid. See *Carbonic acid.*

Cho'ana. (From χεω, to pour out.) It is properly a funnel, but is used to signify the infundibulum of the kidney and brain.

Cho'anus. (χοανα, a funnel.) A furnace made like a funnel, for melting metals.

CHO'COLATE. (Dr. Alston says this word is compounded of two Indian words, *choco,* sound, and *atte,* water; because of the noise made in its preparation.) An article of diet prepared from the cacao-nut; highly nourishing, particularly when boiled with milk and eggs. It is frequently recommended as a restorative in cases of emaciation and consumption.

Chœ'nicis. The trepan, so called by Galen and P. Ægineta, from χοινικις, the nave of a wheel.

Chœ'rades. (From χοιρος, a swine.) The same as scrofula.

Chœradole'thron. (From χοιρος, a swine, and ολεθρος, destruction; so named from its being dangerous if eaten by hogs.) Hogbane. A name in Aëtius for the *Xanthium,* or louse-bur.

Choi'ras. (From χοιρος, a swine; so called because hogs are diseased with it.) The scrofula.

Cho'lades. (From χολη, the bile.) So the smaller intestines are called, because they contain bile.

Chola'go. The same as cholas.

Cholago'ga. (From χολη, bile, and αγω, to evacuate.) *Cholegon.* By cholagogues, the antients meant only such purging medicines as expelled the internal fæces, which resembled the cystic bile in their yellow colour, and other properties.

Cho'las. (From χολη, the bile.) All the cavity of the hypochondrium and part of the ilium is so called, because it contains the liver which is the strainer of the gall.

Cho'le. (χολη.) The bile.

CHOLE'DOCHUS DU'CTUS. (*Choledochus:* from χολη, bile, and δεχομαι, to receive; receiving or retaining the gall.) *Ductus communis choledochus.* The common biliary duct, which conveys both cystic and hepatic bile into the intestinum duodenum.

Chole'gon. The same as cholagoga.

CHO'LERA. (From χολη, bile.) *Diarrhœa cholerica. Felliflua passio.* A genus of disease arranged by Cullen in the class *neuroses,* and order *spasmi.* It is a purging and vomiting of bile, with anxiety, painful gripings, spasms of the abdominal muscles, and those of the calves of the legs. There are two species of this genus: 1. *Cholera spontanea,* which happens, in hot seasons, without any manifest cause. 2. *Cholera accidentalis,* which occurs after the use of food that digests slowly, and irritates. In warm climates it is met with at all seasons of the year, and its occurrence is very frequent; but in England, and other cold climates, it is apt to be most prevalent in the middle of summer, particularly in the month of August; and the violence of the disease has usually been observed to be greater in proportion to the intenseness of the heat. It usually comes on with soreness, pain, distension, and flatulency in the stomach and intestines, succeeded quickly by a severe and frequent vomiting, and purging of bilious matter, heat, thirst, a hurried respiration, and frequent but weak and fluttering pulse. When the disease is not violent, these symptoms, after continuing for a day or two, cease gradually, leaving the patient in a debilitated and exhausted state; but where the disease proceeds with much violence, there arises great depression of strength, with cold clammy sweats, considerable anxiety, a hurried and short respiration, and hiccups, with a sinking, and irregularity of the pulse, which quickly terminate in death; an event that not unfrequently happens within the space of 24 hours.

The appearances generally observed on dissection are, a quantity of bilious matter in the primæ viæ; the ducts of the liver relaxed and distended; and several of the viscera have been found displaced, probably by the violent vomiting. In the early period of the disease, when the strength is not much exhausted, the object is to lessen the irritation, and facilitate the discharge of the bile, by tepid demulcent liquids, frequently exhibited. It will likewise be useful to procure a determination to the surface by fomentations to the abdomen, the pediluvium, or even the warm bath. But where the symptoms are urgent, and the patient appears rapidly sinking from the continued vomiting, violent pain, &c. it is necessary to give opium freely, but in a small bulk; from one to three grains, or even more, in a table spoonful of linseed infusion, or with an effervescing saline draught; which must be repeated at short intervals, every hour perhaps, till relief be obtained. Sometimes, where the stomach could not be got to retain the opium, it has answered in the form of clyster; or a liniment containing it may be rubbed into the abdomen; or a blister, applied over the stomach, may lessen the irritability of that organ. Afterwards the bile may be allowed to evacuate itself downwards; or mild aperients, or clysters, given, if necessary, to promote its discharge. When the urgent symptoms are relieved, the strength must be restored by gentle tonics, as the aromatic bitters, calumba, and the like; with a light nutritious diet: strong toast and water is the best drink, or a little burnt brandy may be added if there is much languor. Exposure to cold must be carefully avoided, particularly keeping the abdomen and the feet warm; and great attention is necessary to regulate the bowels, and procure a regular discharge of bile, lest a relapse should happen. It will also be proper to examine the state of the abdomen, whether pressure give pain at any part, because inflammation in the primæ viæ is very liable to supervene, often in an insidious manner; should that be the case, leeches, blistering the part, and other suitable means, must be promptly resorted to.

Chole′rica. (From χολερα, the cholera.) Medicines which relieve the cholera. Also a bilious flux of the bowels, without pain or fever.

Cholice′le. (From χολη, bile, and χηλη, a tumour.) A swelling formed by the bile morbidly accumulated in the gall-bladder.

Cholo′ma. (From χωλος, lame, or maimed.) Galen says that, in Hippocrates, it signifies any distortion of a limb. In a particular sense, it is taken for a halting, or lameness in the leg.

Chondroglo′ssus. (From χονδρον, a cartilage, and γλωσση, the tongue.) A muscle so named from its insertion, which is in the basis or cartilaginous part of the tongue. See *Hyoglossus*.

CHONDRO′LOGY. (*Chondrologia*; from χονδρος, a cartilage, and λογος, a discourse.) A discourse or treatise on cartilages.

Chondro-pharyngæ′us. (From χονδρος, a cartilage, and φαρυγξ, the upper part of the fauces.) A muscle so named because it rises in the cartilaginous part of the tongue, and is inserted in the pharynx.

Cho′ndros. (*Χονδρος*.) A food of the antients, the same as alica. Also any grumous concretion, and a cartilage.

Chondrosynde′smus. (From χονδρος, a cartilage, and συνδεω, to tie together.) A cartilaginous ligament.

Cho′ndrus. See *Chondros*.

Cho′ne. (Χωνη.) The infundibulum.

Cho′ra. (Χωρα.) A region. Galen, in his book De Usu Partium, expresses by it particularly the cavities of the eyes; but, in others of his writings, he intimates by it any void space.

CHO′RDA. A cord. A tendon. A painful tension of the penis in the venereal disease. See *Chordee*. Sometimes the intestines are called chordæ.

Cho′rda ma′gna. A name of the *tendo Achillis*.

CHO′RDA TY′MPANI. A branch of the seventh pair of nerves that passes through the tympanum.

CHO′RDÆ TENDI′NEÆ. The tendinous and cord-like substances which connect the *carneæ columnæ* of the ventricles of the heart to the auricular valves.

CHO′RDÆ WILLI′SII. The small fibres which cross the sinuses of the dura mater. They are so termed, because Willis first described them.

Chorda′psus. (From χορδη, a cord, and απτω, to knit.) A sort of painful colic, where the intestines appear to be twisted into knots.

CHORDEE′. (*Chordé*. French.) A spasmodic contraction of the penis, that sometimes attends gonorrhœa, and is often followed by a hæmorrhage.

CHO′REA SA′NCTI VI′TI. (*Chorea*, χορεια: from χορος, a chorus, which of old accompanied dancing. It is called St. Vitus's dance, because some devotees of St. Vitus exercised themselves so long in dancing, that their intellects were disordered, and could only be restored by dancing again at the anniversary of St. Vitus.) St. Vitus's dance. Convulsive motions of the limbs, as if the person were dancing. It is a genus of disease arranged by Cullen in the class *neuroses*, and order *spasmi*. These convulsive motions, most generally, are confined to one side, and affect principally the arm and leg. When any motion is attempted to be made, various fibres of other muscles act which ought not; and thus a contrary effect is produced from what the patient intended. It is chiefly incident to young persons of both sexes, and makes its attack between the age of ten and fifteen, occurring but seldom after that of puberty.

By some practitioners it has been considered rather as a paralytic affection than as a convulsive disorder, and has been thought to arise from a relaxation of the muscles, which, being unable to perform their functions in moving the limbs, shake them irregularly by jerks. Chorea sancti Viti is occasioned by various irritations, as teething, worms, offensive smells, poisons, &c. It arises likewise in consequence of violent affections of the mind, as horror, fear, and anger. In many cases it is produced by general weakness; and in a few, it takes place from sympathy, at seeing the disease in others.

The fits are sometimes preceded by a coldness of the feet and limbs, or a kind of tingling sensation, that ascends like cold air up the spine, and there is a flatulent pain in the left hypochondrium, with obstinate costiveness. At other times, the accession begins with yawning, stretching, anxiety about the heart, palpitations, nausea, difficulty of swallowing, noise in the ears, giddiness, and pains in the head and teeth; and then come on the convulsive motions.

These discover themselves at first by a kind of lameness, or instability of one of the legs, which the person draws after him in an odd and ridiculous manner; nor can he hold the arm of the same side still for a moment: for if he lays it on his breast, or any other part of his body, it is forced quickly from thence by an involuntary motion. If he is desirous of drinking, he uses many singular gesticulations before he can carry the cup to his head, and it is forced in various directions, till at length he gets it to his mouth; when he pours the liquor down his throat in great haste, as if he meant to afford amusement to the by-standers. Sometimes various attempts at running and leaping take place, and at others, the head and trunk of the body are affected with convulsive motions. In many instances, the mind is affected with some degree of fatuity, and often shows the same causeless emotions, (such as weeping and laughing,) which occur in hysteria. When this disease arises in children, it usually ceases about the age of puberty; and in adults, is often carried off by a change from the former mode of living. Unless it passes into some other disease, such as epilepsy, it is hardly attended with danger.

The leading indications in the treatment of this complaint are, 1. to obviate the several exciting causes; 2. to correct any faulty state of the constitution, which may appear to give a predisposition; 3. to use those means, which experience has shewn best calculated to allay irregular muscular action. Among the sources of irritation, the most common is the state of the bowels; and the steady, but moderate, use of active cathartics has often a great effect upon the disease, improving the appetite and strength at the same time. Senna, scammony, jalap, &c. may be exhibited according to circumstances, often in conjunction with calomel, particularly where the liver is torpid. The general debility usually attending indicates the employment of tonics, as the cinchona, chalybeates, or sulphate of zinc, which is particularly useful; and with these cold bathing, not too long continued, may be advantageously conjoined; also requiring the patient to use muscular exertion, as much as they can readily, will assist materially in the cure. Sometimes in violent cases, and in irritable constitutions, the occasional exhibition of opium, or other sedative, may be required, taking care, however, that the bowels are not confined thereby. Occasionally too, where the above means are not successful, the more powerful antispasmodics may be tried, as æther, camphor, musk, &c. Electricity also has been by some recommended.

CHO′RION. (From χωρεω, to escape; because it always escapes from the uterus with the fœtus.) Shaggy chorion. The external membrane of the fœtus in utero.

CHO′ROID ME′MBRANE. (*Membrana choroidea*; from χοριον, the chorion, and ειδος, resemblance.) The second tunic of the eye, lying immediately under the sclerotica, to which it is connected by vessels. The true knowledge of this membrane is necessary to a perfect idea of the iris and uvea. The tunica choroidea commences at the optic nerve, and passes forwards, with the sclerotic coat, to the beginning of the cornea transparens, where it adheres very firmly to the sclerotic membrane, by means of a cellular membrane, in the form of a white fringe, called the *ciliary circle*. It then recedes from the sclerotica and cornea and ciliary circle, directly downwards and inwards, forming a round disk, which is variously coloured; hence blue, black eyes, &c. This coloured portion, reflected inwards, is termed the *iris*, and its posterior surface is termed *uvea*. The choroid membrane is highly vascular, and its external vessels are disposed like stars, and termed *vasa vorticosa*. The internal surface of this membrane is covered with a black pigment, called the pigment of the choroid membrane.

CHO′ROID PLE′XUS. *Plexus choroideus.* A plexus of blood vessels, situated in the lateral ventricles of the brain.

Cho′roid tu′nic. See *Choroid membrane.*

Chri′sis. (From χριω, to anoint.) An inunction, or anointing of any part.

Christmas rose. See *Helleborus niger.*

Chri′stum. (From χριω, to anoint.) An unguent, or ointment of any kind.

CHRO′MAS. A chromate, or salt, formed by the union of earthy, metallic, or alkaline bases, with chromic acid; as chromate of lead, &c.

Chromati′smus. (From χρωματιζω, to colour.) The morbid discoloration of any of the secretions, as of the urine, or blood.

CHROME. (From χρωμα, colour; because it is remarkable for giving colour to its combinations.)

Natural History.—This metal, which is extremely scarce, and exists only in combination with oxygen, &c. was discovered by Vauquelin. He found it in an ore called red-lead ore of Siberia, *(chromate of lead.)* The colour of this ore is red, with a shade of yellow; when reduced to powder, it is of a bright orange. Chrome has likewise been found in combination with oxygen, iron, alumine, and silex, *(chromate of iron and alumine,)* in the department of Var, in France. It is met with in irregular masses. Its colour is brown, it has very little metallic lustre. Pontier has lately found chrome combined with oxygen and iron, *(chromate of iron,)* in a quarry near Gussin in the road to Cavalaire. It sometimes forms large masses. The emerald of Peru and spinel ruby owe their colours to this metal.

Properties.—Chrome is obtained in small agglutinated masses of a white colour, inclining to grey; it is very hard, extremely brittle and refractory, and crystallizable at an elevated temperature, in feathered filaments on the surface. Its internal fracture presents in some parts close grains, in other parts needles crossing each other.

Exposed to the heat of a blow-pipe, it is covered with a lilac-coloured crust, which becomes green on cooling. Heated by the same apparatus with borax, it does not melt; but a part, after being oxidized, is dissolved in this salt, and communicates to it a very beautiful green colour. Acids have only a weak action on this metal. The nitric is the only acid which produces any remarkable change, it converts it into an oxide. It is capable of combining with three different portions of oxygen, and forming three different oxides. It has not yet been combined with any combustible body. It does not appear to decompose water. It is unalterable by the alkalies. The other properties of this metal are not yet ascertained, neither are its uses known; perhaps it may afford beautiful and durable colours to the painter or the enameller.

Method of obtaining Chrome.—Chrome is obtained from its native combinations, by decomposing them by the alkaline carbonates, precipitating the chromic acid, and heating it strongly in a crucible.

The following method is recommended by Vauquelin. Seventy-two parts of chromic acid are to be introduced into a charcoal crucible, placed within another of porcelain, filled with charcoal dust. The apparatus is then to be put into a furnace, and subjected to a very strong heat. Metallic chrome will then be found in the charcoal crucible. From seventy-two parts, Vauquelin obtained forty-three of metal.

CHRO′MIC A′CID. This is obtained by decomposing the chromate of lead by potash, and treating the chromate of potash with nitric or muriatic acid. It is of an orange-red colour, and a pungent metallic taste; very soluble in water, and crystallizes by gentle evaporation.

CHRO′NIC. (From χρονος, time.) A term applied to diseases which are of long continuance, and mostly without fever. It is used in opposition to the term acute. See *Acute.*

Chru′psia. (From χροα, colour, and οψις, sight.) *Visus coloratus.* A disease of the eyes, in which the person perceives objects of a different colour from their natural one.

CHRYSA′NTHEMUM. (From χρυσος, gold, and ανθεμον, a flower.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia.* Order, *Polygamia.* Sunflower, or marigold.

2. Many herbs are so called whose flowers are of a bright yellow colour.

Chrysa′nthemum leuca′nthemum. The systematic name of the great ox-eye daisy. *Bellis major. Buphthalmum majus. Leucanthemum vulgare. Bellidioides. Consolida media. Oculus bovis.* Ox-eye daisy. Maudlin wort. The *Chrysanthemum leucanthemum; foliis amplexicaulibus, oblongis, supernè serratis, infernè dentatis*, of Linnæus. The flowers and herb were formerly esteemed in asthmatic and phthisical diseases, but have now deservedly fallen into disuse.

Chry′se. (From χρυσος, gold.) The name of a yellow plaster.

Chrysele′ctrum. (From χρυσος, gold, and ηλεκτρον, amber.) Amber, of a golden yellow colour.

Chrysi′ppea. (From *Chrysippus*, its discoverer.) A herb enumerated by Pliny.

Chrysi′tis. (From χρυσος, gold.) Litharge. The yellow foam of lead. Also the herb yarrow, from the golden colour of its flower.

Chrysoba′lanus. (From χρυσος, gold, and βαλανος, a nut; so named because of its colour, which, before it is dried, is yellow.) The nutmeg.

Chrysoco′lla. (From χρυσος, gold, and κολλη, cement.) Gold solder. Borax.

Chryso′coma. (From χρυσος, gold, and κομη, hair; so called from its golden, hair-like appearance.) The herb milfoil, or yarrow.

Chrysogo′nia. (From χρυσος, gold, and γινομαι, to become.) The tincture of gold.

Chrysola′chanon. (From χρυσος, gold, and λαχανον, a pot-herb; so named from its having a yellow leaf.) The herb orach, or atriplex.

CHRYSOSPLE′NIUM. (From χρυσος, gold, and ασπλενιον, spleenwort.) The name of a genus of plants in the Linnæan system. Class, *Decandria.* Order, *Digynia.* Golden saxifrage.

Chrysu′lcus. (From χρυσος, gold, and ελκω, to take away.) The aqua regia is so called, as having the property to dissolve gold.

Chyla′ria. (From χυλος, chyle.) A discharge of a whitish mucous urine, of the colour and consistence of chyle.

CHYLE. (Χυλος. *Chylus.*) The milk-like liquor observed some hours after eating, in the lacteal vessels of the mesentery, and in the thoracic duct. It is separated by digestion from the chyme, and is that fluid substance from which the blood is formed.

The chyle is absorbed by the mouths of the lacteal vessels, which are in the greatest number in the jejunum and ileum, whilst the fæx of the chyme, with the bile, are propelled into the large intestines. The chyle of the human body smells like milk, has a sweetish taste, a white colour, and a consistence thinner than blood and milk. Its specific gravity is lighter than that of the blood, and hence it is that chyle is occasionally seen swimming on the blood, if a vein be opened some hours after eating. The quality of the chyle is similar to that of milk; for, like it, it coagulates and is acescent: but sometimes its nature is altered from bad digested food or medicines: thus the chyle becomes blue, from eating indigo; yellow, from the yolk of eggs, &c. The quantity of chyle depends upon that of the ingesta, and their greater or less nourishing power: from five or six pounds of food, very little more than two pounds of chyle are elaborated.

The constituent principles of chyle are, 1. *Water*, which forms its greatest part. 2. *Oily cream*, which chemistry teaches to be hydrogen and carbon. 3. *Cheese*, which, by the vis vitalis, is formed by the carbon and azote of the ingested food. 4. *Earth*, which may be obtained from lacteal calculi, that are occasionally found in the receptaculum chyli and lacteals. 5. *Animal lymph*, which is mixed with the gastric and enteric juices.

The nutritive principles of vegetables, are starch, gum, oil, gluten, and sugar. The nutritive principles of animal substances, are gelatin, albumen, fibrin, and oil; and hence the reason why the chyle, separated from vegetables, is of the same nature with that prepared from animal ingesta, because the principles of both are dissolved into their elements, which are the same in animal and vegetable food: thus the *cream* of the chyle is formed of carbon and hydrogen; and the *cheese* of the chyle, from the carbon and azote of both animal and vegetable substances.

The chyle is mixed with the albuminous and gelatinous lymph in the thoracic duct, which receives them from the lymphatics.

The uses of the chyle are, 1. To supply the matter from which the blood and other fluids of our body are prepared; from which fluids the solid parts are formed. 2. By its acescent nature, it somewhat restrains the putrescent tendency of the blood: hence the dreadful putridity of the humours from starving; and thus milk is an excellent remedy against scurvy. 3. By its very copious aqueous latex, it prevents the thickening of the fluids, and thus renders them fit for the various secretions. 4. The chyle secreted in the breasts of puerperal women, under the name of milk, forms the most excellent nutriment of all aliments for new-born infants.

CHYLIFICA′TION. (From *chylus*, and *fio*, to become.) *Chylifactio.* The process carried on in the small intestines, and principally in the duodenum, by which the chyle is separated from the chyme.

Chyli′sma. (From χυλος, juice.) An expressed juice.

CHYLOPOE′TIC. (*Chylopoeticus;* from χυλος, chyle, and ϖοιεω, to make.) Chylopoietic. Any thing connected with the formation of chyle; thus chylopoetic viscera, chylopoetic vessels, &c.

Chylo′sis. (From χυλος, juice.) Chylification, or the changing the food into chyle.

Chylosta′gma. (From χυλος, juice, and ϛαζω, to distil.) The distillation or expression of any juice, or humid part from the rest.

Chylosta′gma diaphore′ticum mindere′ri. A distillation of Venice treacle and mithridate.

CHYME. (*Chymus;* from χυμος, which signifies humour or juice.) The ingested mass of food that passes from the stomach into the duodenum, and from which the chyle is prepared in the small intestines by the admixture of the bile, &c.

Chy′mia. Chemistry.

Chymia′ter. A chemical physician. See *Chimiater.*

Chymia′tria. (From χυμια, chemistry, and ιαομαι, to heal.) The art of curing diseases by the application of chemistry to the uses of medicine.

Chymo′sis. See *Chemosis.*

Chy′nlen radix. A cylindrical root, of the thickness of a goose-quill, brought from China. It has a bitterish taste, and imparts a yellow tinge to the saliva. The Chinese hold it in great estimation as a stomachic, infused in wine.

Chy′sis. (From χυω, to pour out.) Fusion, or the reduction of solid bodies into fluid by heat.

Chy′tlon. (From χυω, to pour out.) An anointing with oil and water.

Ciba′lis fi′stula. An obsolete term for the œsophagus.

Ciba′tio. (From *cibus*, food.) In chemistry, it means incorporation: also the taking of food.

Ci′bur. An obsolete term for sulphur.

CICATRISA′NTIA. (*Cicatrisantia*, sc. *remedia;* from *cicatrico*, to skin over.) Such applications as dispose wounds and ulcers to dry up and heal, and to be covered with a skin.

CICA'TRIX. (From *cicatrico*, to heal up or skin over.) A seam or scar upon the skin after the healing of a sore or ulcer.

CI'CER. (A plant so called. The Cicerones had their name from this pulse, as the Pisones had from the pisum or pea, and the Lentuli from the lens or lentil.)

1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*. Order, *Decandria*. The vetch.

2. The pharmacopœial name of the common cich or ciches.

Ci'cer arie'tinum. The systematic name of the *cicer* plant. *Erebinthus*. *Cicer arietinum; foliis serratis*, of Linnæus. The seeds have been employed medicinally, but are now fallen into disuse. In some places they are toasted, and used as coffee; and in others, ground into a flour for bread. The colour of the arillus of the seed is sometimes white, red, or black; hence the distinction into *cicer album*, *rubrum*, and *nigrum*.

Ci'cera. (From *cicer*, the vetch.) A small pill of the size of a vetch.

Ci'cera ta'rtari. Small pills composed of turpentine and cream of tartar, of the size of a vetch.

CICHO'RIUM. (Originally, according to Pliny, an Egyptian name, and adopted by the Greeks. It is written sometimes Κιχορειον: whence Horace has *cichoreæ*, *levesque malvæ*: sometimes Κιχοριον, or Κιχωριον. It is supposed by some to have this name, *παρα το δια των χωριων κιειν*, from its creeping through the fields. Others derive it from *κιχεω*, *invenio*; on account of its being so readily found, or so common.) Succory.

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*. Order, *Polygamia æqualis*.

2. The pharmacopœial name of the wild cichory. See *Cichorium intybus*.

Cicho'rium endi'via. The systematic name of the endive. *Endivia*. *Endiva*. Endive. This plant, *Cichorium endivia; floribus solitariis, pedunculatis; foliis integris, crenatis*, of Linnæus, is an extremely wholesome salad, possessing bitter and anodyne qualities.

Cicho'rium i'ntybus. The systematic name of the wild succory. *Cichorium*. Succory. This plant, called also *Cichoreum*, *Cichorium sylvestre vel officinarum*, is the *Cichorium intybus; floribus geminis, sessilibus; foliis runcinatis*, of Linnæus.

It belongs to the same family with the garden endive, and by some botanists has been supposed to be the same plant in its uncultivated state; but the endive commonly used as salad is an annual, or at most a biennial plant, and its parent is now known to be the *cichorium endivia*. Wild succory or cichory, abounds with a milky juice, of a penetrating bitterish taste, and of no remarkable smell, or particular flavour: the roots are more bitter than the leaves or stalks, and these much more so than the flowers. By culture in gardens, and by blanching, it loses its bitterness, and may be eaten early in the spring in salads. The roots, if gathered before the stem shoots up, are also eatable, and when dried may be made into bread. The roots and leaves of this plant are stated by Lewis to be very useful aperients, acting mildly and without irritation, tending rather to abate than to increase heat, and which may therefore be given with safety in hectic and inflammatory cases. Taken freely, they keep the belly open, or produce a gentle diarrhœa; and when thus continued for some time, they have often proved salutary in the beginning obstructions of the viscera, in jaundices, cachexies, hypochondriacal and other chronical disorders. A decoction of this herb, with others of the like kind, in whey, and rendered purgative by a suitable addition of polychrest salt, was found an useful remedy in cases of biliary calculi, and promises advantage in many complaints requiring what have been termed attenuants and resolvents. The virtues of succory, like those of dandelion, reside in its milky juice; and we are warranted, says Dr. Woodville, in asserting, that the expressed juice of both these plants, taken in large doses frequently repeated, has been found an efficacious remedy in phthisis pulmonalis, as well as the various other affections above-mentioned. The milky juice may be extracted by boiling in water, or by pressure. The wild and the garden sorts are used indifferently. If the root is cut into small pieces, dried, and roasted, it resembles coffee, and is sometimes a good substitute for it.

Ci'chory. See *Cichorium intybus*.

Ci'chory, wild. See *Cichorium intybus*.

Cicinde'la. (A dim. of *candela*: i. e. a little candle; so called from its light.) The glow-worm. Some think them anodyne, others lithontriptic, though, as the editor of Motherby's Dictionary justly observes, probably neither.

Cici'num oleum. (From *κικι*, the ricinus.) An oil, obtained by boiling the bruised seeds of the *Jatropha curcas* of Linnæus. It is somewhat similar in its properties to castor oil. See *Ricinus*.

Ci'cla. A name for the beta alba.

CICU'TA. (*Quasi cæcuta*, blind; because it destroys the sight of those who use it. Cicuta signifies also the internode, or space between two joints of a reed; or the hollow stem of any plant which the shepherds used for making their rural pipes. *Est mihi disparibus septem conjuncta cicutis fistula.* — Virgil.) Hemlock.

1. The name of a genus of plants in the

Linnæan system. Class, *Pentandria*. Order, *Digynia*.

2. The name, in most pharmacopœias, of the common hemlock. See *Conium*.

Cicu′ta aqua′tica. See *Cicuta virosa*.

Cicu′ta viro′sa. *Cicuta aquatica. Cicutaria virosa. Sium majus alterum angustifolium. Sium erucæ folio.* Long-leaved water hemlock and cowbane. This plant, *Cicuta virosa; umbellis oppositifoliis; petiolis marginatis obtusis*, of Linnæus, is seldom employed medicinally in the present day. It is an active poison, and often eaten by mistake for the wild smallage, the *Apium graveolens* of Linnæus; when it produces tremors, vertigo, a violent burning at the stomach, epilepsy, convulsions, spasms of the jaw, a flowing of blood from the ears, tumefaction of the abdomen, and death.

Cicuta′ria. (*Cicutaria*; from *cicuta*, hemlock.) Bastard hemlock. See *Chærophyllum sylvestre*.

Cicuta′ria aqua′tica. A name for the phellandrium aquaticum.

Cicuta′ria viro′sa. See *Cicuta virosa*.

Cido′nium. See *Pyrus cydonia*.

CI′LIAR LI′GAMENT. (From *cilium*, the eyelid.) *Ligamentum ciliare*. The circular portion that divides the choroid membrane from the iris, and which adheres to the sclerotic membrane. It appears like a white circular ring. See *Choroid membrane*.

Cilia′re ligame′ntum. See *Choroid membrane*.

Cilia′ris mu′sculus. That part of the musculus orbicularis palpebrarum which lies nearest the cilia, considered by Riolan as a distinct muscle.

CI′LIUM. (From *cileo*, to move about.) The eyelid or eyelash.

Ci′liary pro′cesses. The white folds at the margin of the uvea in the eye, covered with a black matter, which proceed from the uvea to the crystalline lens, upon which they lie.

Ci′llo. (From *cilium*, the eyelid.) One who is affected with a spasm or trembling of the eyelids.

Cillo′sis. (From *cilium*, the eyelid.) A spasmodic trembling of the eyelids.

Ci′mex. (From κειμαι, to inhabit; so called because they infest houses.) The wall-louse or bug. *Cimex domesticus*. Six or seven are given inwardly to cure the ague, just before the fits come on, and have the same effect with every thing nauseous and disgusting.

Cimo′lia a′lba. (From Κιμωλος, Cimolus, an island in the Cretan sea, where it is procured.) Tobacco-pipe clay. Its virtues are similar to those of the bolar earths; but it is never administered medicinally.

Cimo′lia purpure′scens. Fullers-earth. A bolar earth, of a greyish-brown colour.

Ci′na ci′næ. See *Cinchona*.

Ci′næ se′men. See *Artemisia santonica*.

CI′NARA. (From κινεω, to move; *quasi movet ad venerem vel urinam*.) Artichoke.

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*. Order, *Polygamia æqualis*.

2. The pharmacopœial name for the common artichoke. See *Cinara scolymus*.

Ci′nara sco′lymus. The systematic name of the artichoke, called in the pharmacopœias *Alcocalum. Articocalus. Artischocas lævis. Costus nigra. Carduus sativus non spinosus. Cinara hortensis. Scolymus sativus. Carduus domesticus capite majore. Carduus altilis. Cinara; foliis subspinosis pinnatis indivisisque, calycinis squamis ovatis*, of Linnæus. A native of the southern parts of Europe, but cultivated here for culinary purposes. The leaves are bitter, and afford, by expression, a considerable quantity of juice, which, when strained, and mixed with an equal quantity of white wine, has been given successfully in dropsies, in the dose of 3 or 4 table-spoonfuls every night and morning, but it is very uncertain in its operation.

CINCHO′NA. (Geoffroy states that the use of this bark was first learned from the following circumstance: — Some cinchona trees being thrown by the winds into a pool of water, lay there till the water became so bitter, that every body refused to drink it. However one of the neighbouring inhabitants being seized with a violent paroxysm of fever, and finding no other water to quench his thirst, was forced to drink of this, by which he was perfectly cured. He afterwards related the circumstance to others, and prevailed upon some of his friends, who were ill of fevers, to make use of the same remedy, with whom it proved equally successful. The use of this excellent remedy, however, was very little known till about the year 1638, when a signal cure having been performed by it on the Spanish viceroy's lady, the Countess del Cinchon, at Lima, it came into general use, and hence it was distinguished by the appellation of *cortex cinchonæ*, and *pulvis comitissæ*, or the Countess's powder. On the recovery of the Countess, she distributed a large quantity of the bark to the Jesuits, in whose hands it acquired still greater reputation, and by them it was first introduced into Europe, and thence called *cortex*, or *pulvis jesuiticus, pulvis patrum*; and also Cardinal del Lugo's powder, because that charitable prelate bought a large quantity of it at a great expence, for the use of the religious poor at Rome.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Monogynia*. Cinchona, or Peruvian bark-tree.

2. The pharmacopœial name of several kinds of barks; called also *Cortex*. *Cortex china, china* or *chinchina; kina kina*, or *kinkina*; and *quina quina*, or *quinquina*. The trees affording which, grow wild in the hilly parts of Peru; the bark is stripped

from the branches, trunk and root, and dried. Three kinds of it are now in use.

CORTEX CINCHONÆ CORDIFOLIÆ.

The plant which affords this species is the *Cinchona cordifolia* of Zea: the *Cinchona officinalis* of Linnæus: the *Cinchona macrocarpa* of Willdenow. Heart-leaved cinchona.

The bark of this tree is called *yellow bark*, (because it approaches more to that colour than either of the others do,) is in flat pieces, not convoluted like the pale, nor dark-coloured like the red; externally smooth internally of a light cinnamon colour, friable and fibrous; has no peculiar odour different from the others, but a taste incomparably more bitter, with some degree of astringency.

CORTEX CINCHONÆ LANCIFOLIÆ.

This species is obtained from the *Cinchona lancifolia* of Zea. Lance-leaved cinchona. This is the *Quilled bark*, which comes in small quilled twigs, breaking close and smooth, friable between the teeth, covered with a rough coat of a brownish colour, internally smooth and of a light brown; its taste is bitter and slightly astringent; flavour slightly aromatic, with some degree of mustiness.

CORTEX CINCHONÆ OBLONGIFOLIÆ.

This kind is procured from the *Cinchona oblongifolia* of Zea. Oblong-leaved cinchona. This bark is the *red bark*: it is in large thick pieces, externally covered with a brown rugged coat, internally more smooth and compact, but fibrous; of a dark-red colour; taste and smell similar to that of the *cinchonæ lancifoliæ cortex*, but the taste rather stronger.

From the general analysis of bark, it appears to consist, besides the woody matter which composes the greater part of it, of gum, resin, gallic acid, of very small portions of tannin and essential oil, and of several salts having principally lime for their basis. Seguin also supposed the existence of gelatin in it, but without sufficient proof. Cold water infused on pale bark for some hours, acquires a bitter taste, with some share of its odour; when assisted by a moderate heat, the water takes up more of the active matter; by decoction, a fluid, deep-coloured, of a bitter styptic taste, is obtained, which, when cold, deposits a precipitate of resinous matter and gallic acid. By long decoction, the virtues of the bark are nearly destroyed, owing to the oxygenation of its active matter. Magnesia enables water to dissolve a larger portion of the principles of bark, as does lime, though in an inferior degree. Alkohol is the most powerful solvent of its active matter. Brandy and other spirits and wines afford also strong solutions, in proportion to the quantity of alkohol they contain. A saturated solution of ammonia is also a powerful solvent; vinegar is less so even than water. By distillation, water is slightly impregnated with the flavour of bark; it is doubtful whether any essential oil can be obtained.

The action of menstrua on the red bark is nearly the same, the solutions only being considerably stronger, or containing a larger quantity of resinous matter and of the astringent principle.

The analysis of the yellow bark, shows that its active principles are more concentrated than in either of the others, affording to water, alkohol, &c. tinctures much stronger both in bitterness, and astringency, especially in the former principle.

From the general analysis of these barks, it appears that they consist of nearly the same proximate principles, which vary in their proportions; the most active component parts are the resin, extractive matter and the gallic acid, and these in combination probably constitute the tonic quality of bark. In the best pale bark, this active matter amounts to about one-eighth.

The red bark has been considered as superior to the pale, the yellow is represented, apparently with justice, as being more active than either of the others.

The effects of Peruvian bark, are those of a powerful and permanent tonic, so slow in its operation, that its stimulating property is scarcely perceptible by any alteration in the state of the pulse, or of the temperature of the body. In a large dose, it occasions nausea and head-ache; in some habits it operates as a laxative; in others it occasions costiveness. It is one of those medicines, the efficacy of which, in removing disease, is much greater than could be expected, *à priori*, from its effects on the system in a healthy state.

Intermittent fever is the disease, for the cure of which bark was introduced into practice, and there is still no remedy which equals it in power.

The disputes respecting the mode of administering it are now settled. It is given as early as possible, with perhaps the previous exhibition of an emetic to evacuate the stomach; it is repeated in the dose of one scruple or half a drachm every second or third hour, during the interval of the paroxysm; and it may even be given during the hot fit, but it is then more apt to excite nausea.

In remittent fever it is given with equal freedom, even though the remission of the fever may be obscure.

In some forms of continued fever which are connected with debility, as in typhus, cynanche maligna, confluent small-pox, &c. it is regarded as one of the most valuable remedies. It may be prejudicial, however, in those diseases where the brain, or its membranes are inflamed, or where there is much irritation, marked by subsultus tendinum, and convulsive motions of the extremities; and in pure typhus it appears to be less useful in the beginning of the disease than in the convalescent stage.

Even in fevers of an opposite type, where there are marks of inflammatory action, particularly in acute rheumatism, bark has been found useful after blood-letting. In erysipelas, in gangrene, in extensive suppuration and venereal ulceration, the free use of bark is of the greatest advantage.

In the various forms of passive hæmorrhagy, in many other diseases of chronic debility, dyspepsia, hypochondriasis, paralysis, rickets, scrofula, dropsy, and in a variety of spasmodic affections, epilepsy, chorea, and hysteria, it is administered as a powerful and permanent tonic, either alone, or combined with other remedies suited to the particular case.

Its usual dose is half a drachm. The only inconvenience of a larger dose is its sitting uneasy on the stomach. It may therefore, if necessary, be frequently repeated, and in urgent cases may be taken to the extent of an ounce, or even two ounces in twenty-four hours.

The powder is more effectual than any of the preparations; it is given in wine, in any spirituous liquor; or, if it excite nausea, combined with an aromatic. The cold infusion is the least powerful, but most grateful; the decoction contains much more of the active matter of the bark, and is the preparation generally used when the powder is rejected; its dose is from two to four ounces. The spirituous tincture, though containing still more of the bark, cannot be extensively used on account of the menstruum, but is principally employed, occasionally, and in small doses of two or three drachms, as a stomachic. The extract is a preparation of considerable power, when properly prepared, and is adapted to those cases, where the remedy requires to be continued for some time. It is then given in the form of pill, in doses of from five to fifteen grains.

Bark is likewise sometimes given in the form of enema; one scruple of the extract, or two drachms of the powder, being diffused in four ounces of starch mucilage. The decoction is also sometimes applied as a fomentation to ulcers.

Cincho′na Caribæ′a. The systematic name of the Caribæan bark-tree. It grows in Jamaica, where it is called the sea-side beech. According to Dr. Wright, the bark of this tree is not less efficacious than that of the cinchona of Peru, for which it will prove an useful substitute; but by the experiments of Dr. Skeete, it appears to have less astringent power.

Cincho′na floribu′nda. The systematic name of the plant which affords the Saint Lucè bark; —*floribus paniculatis glabris, capsulis turbinatis lævibus, foliis ellipticis acuminatis glabris;* it has an adstringent, bitter taste, somewhat like gentian. It is recommended in intermittents, putrid dysentery, and dyspepsia: it should always be joined with some aromatic. Dr. Withering considers this bark as greatly inferior to that of the other species of this genus. In its recent state it is considerably emetic and cathartic, properties which in some degree it retains on being dried; so that the stomach does not bear this bark in large doses, and in small ones its effects are not such as to give it any peculiar recommendation.

Cincho′na officina′lis. The name of the officinal Peruvian bark. See *Cinchona.*

Cincho′na Sa′ncta Fe. Several species of cinchona have been lately discovered at Sancta Fé, yielding barks both of the pale and red kind; and which, from their sensible qualities, are likely upon trial to become equally useful with those produced in the kingdom of Peru.

Cincho′na ru′bra. See *Cinchona.*

Cincho′na fla′va. See *Cinchona.*

Cinci′nnus. The hair on the temples. See *Capillus.*

Cincle′sis. (From κιγκλιζω, to move.) *Cinclismus.* An involuntary nictitation or winking. *Vogel.*

Cinera′rium. (From *cinis,* ashes.) The ash-hole of a chemical instrument.

Ci′neres. (plur. of *cinis,* ashes.) Ashes.

CI′NERES CLAVELLA′TI. (*Clavellatus;* from *clavus,* a wedge. The name of *cineres clavellati* originated from the little wedges or billets into which the wood was cut to make potash.) See *Potassa.*

Ci′neres ru′ssici. See *Potassa impura.*

CINERI′TIOUS. (From *cinis,* ashes.) Of the colour of ashes. A name applied to the cortical substance of the brain, from its resemblance to an ash-colour.

Cineri′tium. (From *cinis,* ashes.) A cupel or test; so named from its being commonly made of the ashes of vegetables or bones.

Cine′rulam. A name for spodium.

Cine′tus. An epithet formerly applied to the diaphragm.

Cingula′ria. (From *cingulum,* a girdle; because it grows in that shape.) The lycopodium.

Ci′ngulum. (From *cingo,* to bind.) A girdle or belt about the loins.

Ci′ngulum mercuria′le. A mercurial girdle, called also *cingulum sapientiæ,* and *cingulum stultitiæ.* It was an invention of Rulandus's; different directions are given for making it, but the following is one of the neatest: "Take three drachms of quicksilver; shake it with two ounces of lemon-juice until the globules disappear; then separate the juice, and mix with the extinguished quicksilver, half the white of an egg; gum-dragon finely powdered, a scruple; and spread the whole on a belt of flannel."

Ci′gulum Sa′ncti Joha′nnis. A name of the artemisia.

Cinifica′tum. A name for calcinatum.

CI′NNABAR. (Pliny says the Indians call by this name a mixture of the blood of the dragon and elephant, and also many substances which resemble it in colour, particularly the minium; but it now denotes the red sulphuret of mercury.) See *Hydrargyri sulphuretum rubrum.*

Cinna′baris facti′tia. See *Hydrargyri sulphuretum rubrum.*

Cinna′baris nati′va. See *Hydrargyri sulphuretum rubrum.*

Cinna′baris Græco′rum. The sanguis draconis and cinnabar.

CINNAMO′MUM. (From *kinamon,* Arab.) Cinnamon. See *Laurus Cinnamomum.*

Cinquefoil. See *Potentilla reptans.*

Ci′on. (Κιων, a column, from κιω, to go.) The uvula was formerly so named from its pyramidal shape; also an enlargement of the uvula.

Cio′nis. (From κιων, the uvula.) A diseased enlargement and painful swelling of the uvula.

CIRCÆ′A. (From *Circe,* the enchantress; so named from the opinion, that it was used by Circe in her enchanted preparations.) Enchanter's nightshade.

1. The name of a genus of plants in the Linnæan system. Class, *Diandria.* Order, *Monogynia.*

2. The name in some pharmacopœias for the *Circæa lutetiana,* which is now fallen wholly into disuse.

CIRCOCE′LE. (κιρσοκηλη: from κιρσος, *varix,* or a dilatation of a vein, and κηλη, a tumour.) *Varicocele.* A varicose distention and enlargement of the spermatic veins; and whether considered on account of the pain, or on account of the wasting of the testicle, which now and then follows, it may truly be called a disease. It is frequently mistaken for a descent of a small portion of omentum. The uneasiness which it occasions, is a kind of pain in the back, generally relieved by suspension of the scrotum. It has been resembled to a collection of earthworms. It is most frequently confined to that part of the spermatic process, which is below the opening in the abdominal tendon; and the vessels generally become rather larger as they approach the testes. There is one sure method of distinguishing between a circocele and omental hernia; place the patient in an horizontal posture, and empty the swelling by pressure upon the scrotum; then put the fingers firmly upon the upper part of the abdominal ring, and desire the patient to rise; if it is a hernia, the tumour cannot re-appear, as long as the pressure is continued at the ring: but if a circocele, the swelling returns with increased size, on account of the return of blood into the abdomen being prevented by the pressure.

Ci′rcos. (From κιρκος, a circle.) A ring. It is sometimes used for the sphincter muscle, which is round like a ring.

CIRCULA′TION. (*Circulatio;* from *circulo,* to compass about.) A vital action performed by the heart in the following manner: the blood is returned by the descending and ascending venæ cavæ into the right auricle of the heart, which, when distended, contracts and sends its blood into the right ventricle; from the right ventricle it is propelled through the pulmonary artery to circulate through, and undergo a change in, the lungs, being prevented from returning into the right auricle by the closing of the valves, which are situated there for that purpose. Having undergone this change in the lungs, it is brought to the left auricle of the heart by the four pulmonary veins, and from thence it is evacuated into the left ventricle. The left ventricle, when distended, contracts, and throws the blood through the aorta to every part of the body, to be returned by the veins into the two venæ cavæ. It is prevented from passing back from the left ventricle into the auricle by a valvular apparatus; and the pulmonary artery and aorta at their origin are also furnished with similar organs, to prevent its returning into the ventricles. — (See *Heart.*) It is by means of this important action, that every part of the body lives, becomes warm, and is nourished, the various secretions are separated, and the chyle converted into blood. In the fœtus the blood passes from the umbilical vein, partly into the vena portæ, and partly through the canalis venosus, into the ascending cava. The lungs being contracted, a very small quantity circulates through them, and the greater part flows through the foramen ovale and canalis arteriosus to the left side of the heart, and into the aorta, and is carried back by the umbilical arteries to the placenta.

Circula′tor. (From *circulo,* to compass about.) A wandering practiser in medicine. A quack. A mountebank.

Circulato′rium. (From *circulo,* to move round.) A chemical digesting vessel in which the fluid performs a circulatory motion.

CI′RCULUS. (Dim. of *circus,* a circle.) A circle or ring. Any part of the body which is round or annular, as circulus oculi. A round chemical and chirurgical instrument sometimes called abbreviatorium by the old chemists.

Ci′rculus arterio′sus i′ridis. The artery which runs round the iris and forms a circle, is so termed.

Ci′rculus quadru′plex. A bandage.

Circumcaula′lis. A name of the adnata of the eye.

CIRCUMCI′SION. (*Circumcisio,* from *circumcido,* to cut about.) The cutting off the prepuce from the glans penis; an ancient custom, still practised amongst the Jews.

CIRCUMFLE′XUS. (*Circumflexus, sc. musculus.*) *Tensor palati* of Innes. *Circumflexus palati mollis* of Albinus. *Spheno-salpingo-staphilinus, seu staphilinus externus* of Winslow. *Musculus tubæ novæ* of Valsalva. *Palato-salpingeus* of Douglas. *Pterigo-staphylinus* of Cowper, and *Petrosalpingo-staphilin* of Dumas. This muscle arises from the spinous process of the sphenoid bone, behind the foramen ovale, which transmits the third branch of the fifth pair of nerves; from the Eustachian tube, not far from its osseous part; it then runs down along the pterygoideus internus, passes over the hook of the internal plate of the pterygoid process by a round tendon, which soon spreads into a broad membrane. It is inserted into the velum pendulum palati, and the semilunar edge of the os palati, and extends as far as the suture which joins the two bones. Generally some of its posterior fibres join with the constrictor pharyngis superior, and palato-pharyngæus. Its use is to stretch the velum, to draw it downwards, and to the side towards the hook. It hath little effect upon the tube, being chiefly connected to its osseous part.

Circumgyra′tio. (From *circumgyro*, to turn round.) Circumgyration, or the turning a limb round in its socket.

Circumli′tio. (From *circumlino*, to anoint all over.) A medicine used as a general unction or liniment to the part.

Circumossa′lis. (From *circum*, about, and *os*, a bone.) Surrounding a bone as the periosteum does; or surrounded by a bone.

Ci′rcus. (*κιρκος*: from *carka*, to surround. Chald.) A circle or ring. A circular bandage, called also plinthius laqueus.

Cirne′sis. (From *κιρναω*, to mix.) An union of separate things.

Ci′rsium arve′nse. (From *κιρσος*, a vein or swelling of a vein, which this herb was supposed to heal.) The carduus hæmorrhoidalis.

Cirsoce′le. See *Circocele.*

Cirsoi′des. (From *κιρσος*, a varix, and *ειδος*, likeness.) Resembling a varix: an epithet applied by Rufus Ephesius to the upper part of the brain.

Ci′rsos. (*κιρσος*: from *κιρσοω*, to dilate.) A varix or preternatural distention of any part of a vein.

Ci′ssa. (From *κισσα*, a gluttonous bird.) A depraved appetite proceeding from previous gluttony and voracity.

CISSA′MPELOS. (From *κισσος*, ivy, and *αμπελος*, the vine.) The name of a genus of plants in the Linnæan system. Class, *Dioecia.* Order, *Monadelphia.* The wild vine with leaves like ivy.

Cissa′mpelos parei′ra. The systematic name of the *pareira brava. Pareyra. Ambutua. Butua. Overo butua.* The root of this plant, (*Cissampelos pareira; foliis peltatis cordatis emarginatis*, of Linnæus; a native of South America and the West Indies,) has no remarkable smell, but to the taste it manifests a notable sweetness of the liquorice kind, together with a considerable bitterness, and a slight roughness covered by the sweet matter. The facts adduced on the utility of the *radix pareiræ bravæ* in nephritic and calculous complaints, are principally by foreigners, and no remarkable instances of its efficacy are recorded by English practitioners.

Cissa′rus. See *Cistus Creticus.*

Cissi′num. (From *κισσος*, ivy.) The name of a plaster mentioned by Ægineta.

CI′STA, (From *κειμαι*, to lie.) A cyst.

Ciste′rna. (From *cista*, a cyst.) The fourth ventricle of the brain is so called from its cavity; also the lacteal vessels in women.

Ci′sthorus. See *Cistus Creticus.*

CI′STUS. (*Κιστος*, the derivation of which is uncertain; perhaps from *kis*, Heb.) The name of a genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Monogynia.* The Cistus.

Cistus cre′ticus. *Cistus ladanifera. Cisthorus. Cissarus. Dorycinium.* The systematic name of the plant from which the ladanum of the shops is obtained; called also *Labdanum.* This resinous juice exudes upon the leaves of the *Cistus creticus; arborescens extipulatus, foliis spatulato-ovatis petiolatis enerviis scabris, calycinis lanceolatis;* of Linnæus, in Candia, where the inhabitants collect it by lightly rubbing the leaves with leather, and afterwards scraping it off, and forming it into irregular masses for exportation. Three sorts of ladanum have been described by authors, but only two are to be met with in the shops. The best, which is very rare, is in dark-coloured masses, of the consistence of a soft plaster, and growing still softer on being handled; the other is in long rolls, coiled up, much harder than the preceding, and not so dark. The first has commonly a small, and the last a large admixture of fine sand, without which they cannot be collected pure, independently of designed abuses: the dust blown on the plant by winds, from the loose sands among which it grows, being retained by the tenacious juice. The soft kind has an agreeable smell, and a lightly pungent bitterish taste: the hard is much weaker. Ladanum was formerly much employed internally as a pectoral and adstringent in catarrhal affections, dysenteries, and several other diseases; at present, however, it is wholly confined to external use, and is an ingredient in the stomachic plaster, *emplastrum ladani.*

Ci′stus hu′milis. A name of parnassia or white liverwort.

Ci′stus ladani′fera. See *Cistus Creticus.*

Ci'stus le'don. A name of Ledum palustre. See *Rosmarinus*.

CITE'SIUS (Citois), Francis, of Poitiers in France, who, after graduating at Montpelier in 1596, and practising a few years in his native city, went to Paris, and acquired great celebrity, being made physician to Cardinal Richelieu. He published a treatise on the Colica Pictonum, which was much esteemed, noticing its termination in paralysis of the extremities. He also gave an account of a girl who had fasted for three years; but in this case appears to have been imposed upon. In another publication he advocates repeated bleeding, as well as purging, in small-pox, and other fevers of an inflammatory type. He died in 1652, at the advanced age of 80.

Ci'tharus. (From κιθαρα, a harp.) The breast is sometimes so named from its shape.

Citra'go. (From *citrus*, a citron, so called from its citron-like smell.) *Citraria.* Melissa or baum.

CI'TRAS. (*-atis*, fœm.: from *citrus*, the lemon.) A citrate. A salt formed by the union of the citric acid, or acid of lemons, with different bases; as *citrate of ammonia*, *citrate of potash*.

Ci'trea. See *Citrus medica*.

CI'TREUM. (From *citrus*.) The citron-tree. See *Citrus medica*.

CI'TRIC A'CID. *Acidum citricum.* The acid of lemons. The citric acid may be obtained pure in concrete crystals, by the following method: Saturate boiling lemon-juice with pulverised chalk. The acid forms with lime a salt that is scarcely soluble, and the mucilaginous and extractive substances remain dissolved in the supernatant liquor; the precipitate is to be well washed with lukewarm water; it is then to be treated with as much sulphuric acid as would have been requisite to saturate the chalk, diluted in ten parts of water; and this mixture is to be boiled for a few minutes. Afterwards, it must be cooled and filtered; the sulphate of lime remains on the filter, and the liquor affords a crystallized acid by evaporation.

Citrina'tio. Complete digestion.

Citri'nula. (A dim. of *citrus*.) A small citron.

Citron. See *Citrus medica*.

Citrul, Sicilian. See *Cucurbita citrullus*.

Citru'llus. See *Cucurbita Citrullus*.

CI'TRUS. 1. The name of a genus of plants in the Linnæan system. Class, *Polyadelphia*. Order, *Icosandria*.

2. The name of the lemon. See *Citrus medica*.

Ci'trus aura'ntium. The systematic name of the orange tree. *Aurantium. Aurantium hispalense. Malus aurantia major. Malus aurantia. Aurantium vulgare. Malus aurantia vulgaris. Mala aurea. Chrysomelea. Nerantia. Martianum pomum. Poma aurantia.* Seville orange. This plant is the *Citrus aurantium petiolis alatis, foliis acuminatis*, of Linnæus. The China and Seville orange are both only varieties of the same species; the latter is specified in our pharmacopœias; and the *flowers*, *leaves*, *yellow rind* and *juice*, are made use of for different medical purposes.

The flowers, *flores naphæ*, are highly odoriferous, and are used as a perfume; they are bitter to the taste; they give their taste and smell both to water and to spirit, but most perfectly to rectified spirit of wine. The water which is distilled from these flowers, is called *aqua florum naphæ*. In distillation, they yield a small quantity of essential oil, which is called *oleum* vel *essentia neroli:* they are brought from Italy and France. Orange flowers were, at one time, said to be an useful remedy in convulsive and epileptic cases; but experience has not confirmed the virtues attributed to them.

The *leaves* have a bitterish taste, and yield, by distillation, an essential oil; indeed, by rubbing them between the fingers and the thumb, they manifest considerable fragrance. They have been applied for the same purposes as the flowers, but without success.

The *yellow rind* of the fruit, freed from the white fungous part, has a grateful aromatic flavour, and a warm, bitterish taste. Infused in boiling water, it gives out nearly all its smell and taste; cold water extracts the bitter, but very little of the flavour. In distillation, a light, fragrant, essential oil rises, without the bitter. Its qualities are those of an aromatic and bitter. It has been employed to restore the tone of the stomach, and is a very common addition to combinations of bitters, used in dyspepsia. It has likewise been given in intermittents, in doses of a drachm, twice or thrice a day. It is also much celebrated as a powerful remedy, in menorrhagia, and immoderate uterine evacuations.

The *juice* of Seville oranges is a grateful acid, which, by allaying heat, quenching thirst, promoting various excretions, and diminishing the action of the sanguiferous system, proves extremely useful in both ardent and putrid fevers; though the China orange juice, as impregnated with a larger proportion of sugar, becomes more agreeable, and may be taken in larger quantities. The Seville orange juice is particularly serviceable as an antiscorbutic, and alone will prevent or cure scurvy in the most apparently desperate circumstances. In dyspepsia, from putrid bile in the stomach, both lemon and orange juice are highly useful.

Ci'trus me'dica. The systematic name of the lemon-tree. *Limon. Limonia mala. Malus medica. Malus limonia acida. Citrea malus. Citrus.* The tree which affords the lemon, is the *Citrus medica petiolis linearibus*, of Linnæus: a native of the upper part of Asia, but cultivated in

Spain, Portugal, and France. The juice, which is much more acid than that of the orange, possesses similar virtues. It is always preferred where a strong vegetable acid is required. Saturated with the fixed vegetable alkali, it forms the citrate of potash, which is in frequent extemporaneous use in febrile diseases, and by promoting the secretions, especially that of the skin, proves of considerable service in abating the violence of fever. This medicine is also often employed to restrain vomiting. As an antiscorbutic, lemon juice has been often taken on board ships destined for long voyages; but even when well depurated of its mucilaginous parts, it is found to spoil by long keeping. To preserve it in purity for a considerable length of time, it is necessary that it should be brought to a highly concentrated state, and for this purpose it has been recommended to expose the juice to a degree of cold sufficient to congeal the aqueous and mucilaginous parts. After a crust of ice is formed, the juice is poured into another vessel; and, by repeating this process several times, the remaining juice, it is said, has been concentrated to eight times its original strength, and kept without suffering any material change for several years. Whytt found the juice of lemons to allay hysterical palpitations of the heart, after various other medicines had been experienced ineffectual; and this juice, or that of oranges, taken to the quantity of four or six ounces in a day, has sometimes been found a remedy in the jaundice. The exterior rind of the lemon is a very grateful aromatic bitter, not so hot as orange-peal, and yielding in distillation a less quantity of oil, which is extremely light, almost colourless, and generally brought from the southern parts of Europe, under the name of Essence of Lemons. The lemon-peel, though less warm, is similar in its qualities to that of the orange, and is employed with the same intentions. The pharmacopœias direct a syrup of the juice, *syrupus limonum*, and the peel enters into some vinous and aqueous bitter infusions; it is also ordered to be candied; and the essential oil is an ngredient in some formulæ.

The citron-tree is also considered as belonging to the same species, the *Citrus medica* of Linnæus. Its fruit is called *Cedromela*, which is larger and less succulent than the lemon; but in all other respects the citron and lemon trees agree. The citron juice when sweetened with sugar is called by the Italians *agro di cedro*. The *Citrus mella rosa* of Lamarck, is another variety of the *citrus medica* of Linnæus. It was produced, at first, casually, by an Italian's grafting a citron on a stock of a bergamot pear-tree; whence the fruit produced by this union participated both of the citron-tree and the pear-tree. The essence prepared from this fruit is called essence of bergamote and essentia de cedra.

Ci'tta. A voracious appetite.

Citto'sis. See *Chlorosis.*

Civet-cat. See *Zibethum.*

CIVE'TTA. (From *sebet.* Arab.) Civet, an unctuous odoriferous drug now only used by perfumers.

Clap. See *Gonorrhœa.*

CLA'RET. (*Claretum*; from *clareo*, to be clear.) A French wine, that may be given with great advantage, as a tonic and antiseptic, where red port wine disagrees with the patient; and in typhoid fevers of children and delicate females, it is far preferable, as a common drink.

Clare'tum. See *Claret.* Also a wine impregnated with spices and sugar, called by some *Vinum Hippocraticum.* A *Claretum purgatorium* composed of a vinous infusion of glass of antimony with cinnamon water and sugar, is mentioned by Schroeder.

CLARIFICA'TIO. The depuration of any thing.

Clary. A name for the *horminum.*

Cla'sis. (From κλαω, to break.) *Clasma.* A fracture.

Clau'strum. (From *claudo*, to shut.) *Cleithrum gutturis.* Any aperture which has a power of contracting itself, or closing its orifice by any means, as the passage of the throat.

Cla'ustrum virginita'tis. The hymen.

CLAUSU'RA. (From *claudo*, to shut.) An imperforation of any canal or cavity in the body. Thus *clausura uteri* is a preternatural imperforation of the uterus; *clausura tubarum Fallopiarum*, a morbid imperforation of the Fallopian tubes, mentioned by Ruysch as one cause of infecundity.

Clava'tio. (From *clava*, a club.) A sort of articulation without motion, where the parts are, as it were, driven in with a hammer, like the teeth in the sockets. See *Gomphosis.*

Clavella'tus. (From *clavus*, a wedge.) Potash was called cineres clavellati, from the little wedges, or billets, into which the wood was cut to make it.

CLA'VICLE. (Dim. of *clavis*; so called from its resemblance to an antient key.) Collar-bone. The clavicle is placed at the root of the neck, and at the upper part of the breast. It extends across, from the tip of the shoulder to the upper part of the sternum; it is a round bone, a little flattened towards the end, which joins the scapula; it is scurved like an Italic *S*, having one curve turned out towards the breast, it is useful as an arch, supporting the shoulders, preventing them from falling forwards upon the breast, and making the hands strong antagonists to each other; which, without this steadying, they could not have been.

1. The thoracic end, that next the sternum, or what may be called the inner head of the clavicle, is round and flat, or button-like; and it is received into a suitable hollow on the upper piece of the sternum.

It is not only like other joints surrounded by a capsule or purse; it is further provided with a small moveable cartilage, which, like a friction-wheel in machinery, saves the parts and facilitates the motions, and moves continually as the clavicle moves.

2. But the outward end of the clavicle is flattened, as it approaches the scapula, and the edge of that flatness is turned to the edge of the flattened acromion, so that they touch but in one single point. This outer end of the clavicle, and the corresponding point of the acromion, are flattened and covered with a crust of cartilage; but the motion here is very slight and quite insensible; they are tied firmly by strong ligaments; and we may consider this as almost a fixed point; for there is little motion of the scapula upon the clavicle: but there is much motion of the clavicle upon the breast, for the clavicle serves as a shaft, or axis, firmly tied to the scapula, upon which the scapula moves and turns, being connected with the trunk only by this single point, viz. the articulation of the clavicle with the breast-bone.

Clavi′culus. See *Clavicle.*

Clavi′cula. See *Clavicle.*

Cla′vis. (From *claudo*, to shut.) The same as clavicle.

CLA′VUS. (A nail.) The sensation resembling the driving a nail into the head. A fixed pain in the forehead, which may be covered by one's thumb, giving a sensation like as if a nail were driven into the part. When connected with hysterics, it is called *clavus hystericus.* This term is also applied to *corns,* from their resemblance to the head of a nail; and to an artificial palate, or diseased uterus.

Cla′vus hyste′ricus. See *Clavus.*

Cla′vus oculo′rum. A staphyloma, or tumour on the eyelids.

Clay. See *Alumine.*

Cleavers. See *Galium Aparine.*

CLEGHORN, George, was born near Edinburgh in 1716; and after studying in that city, went at the age of 20 to Minorca, as a regimental surgeon. During the 13 years that he spent there, he sedulously studied the natural productions of the island. In 1750, coming to London, he published his "Treatise on the Diseases of Minorca," which displays great observation and ability. He then went to Dublin, and gave lectures on anatomy with such success, that he was soon after appointed public professor; and in 1774, an honorary member of the College of Physicians there. He died in 1789.

Clei′dion. *Clidion.* The epithet of a pastil, described by Galen and Paulus Ægineta; and it is the name also of an epithem described by Aetius.

Cleido′ma. (From κλειδοω, to close.) A pastil, or troch. Also the clavicula.

Cleidomastoide′us. (From κλεις, the clavicle, and μαςοειδης, the mastoid process.) See *Sterno-cleido-mastoideus.*

Cleisa′gra. (From κλεις, the clavicle, and αγρα, a prey.) The gout in the articulation of the clavicles.

Clei′thron. (From κλειδω, to shut.) See *Claustrum.*

CLE′MATIS. (From κλημα, a tendril; so named from its climbing up trees, or any thing it can fasten upon with its tendrils.) The name of a genus of plants in the Linnæan system. Class, *Polyandria.* Order, *Polygynia.*

Cle′matis re′cta. The systematic name of the upright virgin's-bower. *Flammula Jovis.* *Clematis; foliis pinnatis, foliolis ovato lanceolatis integerrimis, caule erecto, floribus pentapetalis tetrapetalisque* of Linnæus. More praises have been bestowed upon the virtue which the leaves of this plant are said to possess, when exhibited internally, as antivenereal, by foreign physicians, than its trials in this country can justify. The powdered leaves are sometimes applied externally to ulcers, as an escharotic.

Cle′matis vita′lba. The systematic name of the traveller's-joy. *Vitalba. Viorna.* *Clematis arthragene* of Theophrastus. This plant is common in our hedges, and is the *Clematis; foliis pinnatis, foliolis cordatis scandentibus,* of Linnæus. Its leaves when fresh produce a warmth on the tongue, and if the chewing is continued, blisters arise. The same effect follows their being rubbed on the skin. The plant has been administered internally to cure lues venerea, scrofula, and rheumatisms. In France, the young sprouts are eaten, when boiled, as hoptops are in this country.

Clemati′tis. The same as clematis.

Cleo′nis colly′rium. The name of a collyrium described by Celsus.

Cleo′nis glu′ten. An astringent formula of myrrh, frankincense, and white of egg.

Cle′psydra. (From κλεπτω, to conceal, and υδωρ, water.) Properly, an instrument to measure time by the dropping of water through a hole, from one vessel to another; but it is used to express a chemical vessel, perforated in the same manner. It is also an instrument mentioned by Paracelsus, contrived to convey suffumigations to the uterus in hysterical cases.

CLEYER, Andrew, was born at Cassel, in the beginning of the 17th century. After studying medicine, he went as physician to Batavia, where he resided several years. He transmitted several interesting communications to the Imperial Academy, of which he had been chosen a member, particularly "An Account of Hydatids found in a Human Stomach," and "Of the Custom of the Indians of taking Opium;" also descriptions and drawings of the plants indigenous in Java, especially the moxa ginseng, and tea-plant. He likewise published, in 1680, a curious specimen of Chinese medicine.

Cli'banus. (Quasi *καλιϐανος*: from *καλυπτω*, to conceal.) A portable furnace, or still, in which the materials to be wrought on are shut up.

CLIFTON, Francis, after studying at Oxford, came to London, and was admitted Fellow of the College of Physicians, as well as of the Royal Society, about the year 1730. Two years after he published on "The State of Physic, antient and modern, with a Plan for improving it;" in which a law is proposed, to compel practitioners to send to a public institution descriptions of the several cases which come under their care. He was also author of "A plain and sure Way of practising Physic;" and translated some parts of Hippocrates into English, with notes.

Clima'cter. (From *κλιμαζω*, to proceed gradually.) The progression of the life of man. It is usually divided into periods of seven years.

Cli'max. (From *κλιμαζω*, to proceed.) A name of some antidotes, which, in regular proportion, increased or diminished the ingredients of which it was composed, e. g. ℞. *Chamædryos* ℥jjj. *Centaurii* ℥jj. *Hyperici* ℥j.

Climbing birthwort. See *Aristolochia clematitis.*

CLI'NICAL. (*Clinicus*; from *κλινη*, a bed.) Any thing concerning a bed: thus clinical lectures, notes, a clinical physician, &c.; which mean lectures given at the bedside, observations taken from patients when in bed, a physician who visits his patients in their bed, &c.

CLI'NOID. (*Clinoideus*; from *κλινη*, a bed, and *ειδος*, resemblance.) Resembling a bed. The four processes surrounding the sella turcica of the sphenoid bone are so called, of which two are anterior, and two posterior.

Clinomastoide'us. A corruption of cleidomastoideus.

Cli'ssus. A chemical term denoting mineral compound spirits; but antimony is considered as the basis clyssi. See *Clyssus.*

Clito'ridis mu'sculus. See *Erector clitoridis.*

CLI'TORIS. (From *κλειω*, to enclose, or hide; because it is hid by the labia pudendorum.) *Columella.* A small glandiform body, like a penis in miniature, and, like it, covered with a præpuce, or fore-skin. It is situated above the nymphæ, and before the opening of the urinary passage of women. Anatomy has discovered, that the clitoris is composed, like the penis, of a cavernous substance, and of a glans, which has no perforation, but is like that of the penis, exquisitely sensible. The clitoris is the principal seat of pleasure: during coition it is distended with blood, and after the venereal orgasm it becomes flaccid and falls. Instances have occurred where the clitoris was so enlarged as to enable the female to have venereal commerce with others; and, in Paris, this fact was made a public exhibition of to the faculty. Women thus formed appear to partake, in their general form, less of the female character, and are termed hermaphrodites. The clitoris in children is larger, in proportion, than in full-grown women: it often projects beyond the external labia at birth.

Clitori'smus. (From *κλειτορις*.) A morbid enlargement of the clitoris.

CLO'NIC. (From *κλονεω*, to move to and fro.) See *Convulsion.*

Clono'des. (From *κλονεω*, to agitate.) A strong unequal pulse.

Clove bark. See *Myrtus caryophyllata.*

Clove gilliflower.
Clove July flower. } See *Dianthus Caryophyllus.*
Clove pink.

Clove. See *Eugenia Caryophyllata.*

CLOWES, William, an eminent English surgeon of the 16th century, received his education under George Keble, whose skill he strongly commends. After serving for some time professionally in the navy, he settled in London, and was made surgeon to Christ's and St. Bartholomew's hospitals, and appears to have had considerable practice. In 1586 he was sent to the Low-Countries, to the assistance of the army under the Earl of Leicester; and on his return was appointed surgeon to the Queen. His works are in the English language, but evince much learning, as well as skill in his profession. The first which he published was on the lues venerea, in 1585; in which he notices the increasing frequency of that disease, and states that in five years he had cured above a thousand patients labouring under it at St. Bartholomew's hospital. But his most celebrated publication appeared three years after, on the method of treating wounds of various kinds, the result of extensive experience, sanctioned by references to the most approved writers. He appears to have possessed an enlarged understanding, and was very severe on all quacks and impostors; and he may justly be reckoned among the restorers and improvers of surgery in modern times.

CLUNE'SIA. (From *clunes*, the buttocks.) *Proctalgia.* An inflammation of the buttocks.

Clu'pea alo'sa. The Linnæan name for the shad or chad, whose flesh is by some commended as a restorative.

CLU'SIA. (So called in memory of Charles Clusius, an eminent botanist.) The name of a genus of plants in the Linnæan system. Class, *Polygamia.* Order, *Monoecia.* Balsam-tree.

CLU'TIA. (Named after Cluyt, and sometimes spelt *cluytia.*) The name of a genus of plants in the Linnæan system. Class, *Dioecia.* Order, *Gynandria.*

Clu′tia eluthe′ria. The systematic name of the tree which is by some supposed to afford the cascarilla bark.

Cluy′tia. See *Clutia.*

Cly′don. (Κλυδων.) A fluctuation and flatulency in the stomach.

Clypea′lis. (From *clypeus*, a shield.) Formed like a shield.

Cly′smus. *Clysma.* (From κλυζω, to wash.) A glyster.

Cly′ssus. *Clissus.* A term antiently used by the chemists for medicines made by the re-union of different principles, as oil, salt, and spirit, by long digestion; but it is not now practised, and the term is almost lost.

Cly′ssus antimo′nii. *Clyssus mineralis.* A weak acid of sulphur.

Cly′ster. (*Clysterium.* From κλυζω, to cleanse.) A glyster.

Cne′mia. Any part connected with the tibia.

Cnemodactylæ′us. (From κνημη, the tibia, and δακτυλος, a finger, or toe.) A muscle whose origin is in the tibia, and whose insertion is in the toes. Its office is to elevate the toes. See *Extensor longus digitorum pedis.*

Cne′sis. (From κναω, to scratch.) *Cnesma.* *Cnesmos.* A painful itching.

Cnicilæ′on. (From κνικος, cnicus, and ελαιον, oil.) Oil made of the seeds of cnicus. Its virtues are the same with those of the ricinus, but in an inferior degree.

Cni′cus. (From κναω, to scratch.) The plant used by Hippocrates by this name, is supposed to be the carthamus; but modern botanists exclude it from the species of this plant.

Cni′cus sylve′stris. The *Centaurea benedicta.*

Cni′dii co′cci.
Cni′dia gra′na. } See *Daphne Mezereum.*

Cnido′sis. (From κνιδη, the nettle.) An itching sensation, such as is perceived from the nettle. A dry ophthalmy.

Cnipo′tes. An itching.

Cni′smos. See *Cnesis.*

Cny′ma. (From κναω, to scrape, or grate.) In Hippocrates it signifies a rasure, puncture, or vellication: also the same as cnesmos, or cnesis.

COAGULA′NTIA. (From *coagulo*, to incrassate, or curdle.) Such medicines as coagulate the blood and juices flowing from it.

COA′GULABLE LYMPH. *Lympha coagulabilis.* Called also fibrin, being a principal constituent of muscular fibres. It is a component part of the blood. It may be obtained in considerable quantities, by stirring the blood about with a stick, when it adheres to its sides. In certain diseased actions it is separated from the blood, and is often found in very considerable quantities in the circumscribed cavities of the body. It has neither taste nor smell; it always possesses a white and opake colour; is of a glutinous consistence, and, if dried by a gentle heat, becomes horny. The same name has also been given to that part of the serum, which coagulates when heated, and which is of an albuminous nature. See *Albumen.*

COAGULA′TION. (*Coagulatio*: from *con*, and *ago*, to drive together.) The separation of the glutinous or viscid particles, contained in any fluid, from the more thin and not coagulable particles: thus, when milk curdles, the coagulable particles form the curd; and when acids are thrown into any fluid containing coagulable particles, they form what is called a *coagulum.*

COA′GULUM. A term applied frequently to blood and other fluids, when they assume a jelly-like consistency.

Coa′gulum alu′minis. This is made by beating the white of eggs with a little alum, until it forms a coagulum. It is recommended as an efficacious application to relaxations of the conjunctive membrane of the eye.

Coalte′rnæ fe′bres. (From *con*, and *alternus*, alternate.) Fevers mentioned by Bellini, which he describes as two fevers affecting the same patient, and the paroxysm of one approaching as that of the other subsides.

Coarcta′tio. (From *coarcto*, to straiten.) The contraction, or diminution of any thing. Applied to the pulse, it means a lessening in number.

Coarticula′tio. (From *con*, and *articulatio*, an articulation.) That sort of articulation which has manifest motion.

CO′BALT. *Cadmia metallica.* A metal that has never been found pure in nature. We meet with it almost always either in the state of an oxide, alloyed with other metals, in the form of a sulphuret, or combined with an acid.

Cobalt in the state of an oxide forms the *black cobalt ore.* This ore is found in Germany, either in powder of a black or grey colour, or in compact masses. In the last form, it exhibits at its fracture rose-coloured spots. There are several varieties of this ore.

Cobalt, alloyed with other metals, forms the *dull white cobalt ore.* In this ore, which occurs either amorphous or crystallized, cobalt is united to iron and arsenic. The colour of this ore, when fresh broken, is white or blueish-grey, sometimes with a shade of red. It has a metallic lustre. Its texture is compact. Cobalt, united to sulphur, forms the *white cobalt ore.* It is met with in masses, or crystallized in cubes, dodecahedra, and octahedra. Its colour is a tin-white, sometimes reddish-yellow. Cobalt in the state of oxide, combined with arsenic, acid forms the *red cobalt ore*, arseniate of cobalt. It is found in masses of various shapes. Its colour is red, inclining to orange.

Cobalt, when in a pure state, is of a steel-grey colour, with a tinge of red, and a fine close grain. It has a granulated fracture, and is easily broken and pulverized. Its specific weight is between 7.700 and 7.811. It requires a very intense heat for its fusion, nearly equal to that necessary to melt cast-iron. When heated in contact with the air, it oxidizes before fusion. Phosphorus renders it very fusible, and converts it into a phosphuret. It unites to sulphur with difficulty, but very well with the alkaline sulphurets by fusion. When alloyed with metals it renders them granulated, rigid, and brittle. It is attacked by the greater number of the acids, and unites with the boracic acid. Its solutions in different acids become green when heated; and from this property, it is used as an ink, which, when written with on paper, is invisible, but becomes visible when gently heated, and disappears when cold. It takes fire in oxygenated muriatic acid gas. It colours glass of a fine blue. It unites with platina, gold, iron, nickel, copper, and arsenic, by fusion; but silver, lead, bismuth, and mercury, refuse to unite with it in the dry way. In its purest state, it is not only obedient to the magnet, but, if we may trust to the accuracy of some experiments made by Kohl and Wenzel, it may even receive a magnetical attractive power.

Nitrate of potash oxidizes cobalt readily. It detonates by the blow of a hammer when mixed with oxygenated muriate of potash. It produces fine colours in porcelain, enamels, artificial gems, &c.

COBHAM WATERS. Weak saline purging waters.

CO′BRA DE CAPE′LLO. (From *cobra*, the head, or covering, Span.) *Crotalus horridus* of Linnæus. The rattlesnake; the stone out of whose head is said to be an antidote to the poison of venomous animals.

Co′cca cni′dia. See *Daphne mezereum*.

Cocca′rium. (From κοκκον, a berry.) A very small pill.

COCCINE′LLA. (Dim. from *coccus*, a berry; from its resemblance to a berry.) See *Coccus cacti*.

Cocco-ba′lsamum. The fruit of the true balsam.

Coccogni′dia. *Grana cnidia*. *Cocci cnidii*. The seeds of the *Daphne mezereum* are so termed. They are violently purgative. See *Daphne mezereum*.

Co′ccos. See *Daphne mezereum*.

Co′cculi I′ndi aroma′tici. The piper Jamaicense.

CO′CCULUS I′NDICUS. (Dim. of κοκκος, a berry.) See *Menispermum cocculus*.

Co′ccum ba′phicum. A name for chermes.

CO′CCUS. The name, in entomology, of a tribe of insects.

Co′ccus ca′cti. The systematic name of the cochineal animal. *Coccinella*. *Coccinilla*. *Ficûs Indiæ grana*. *Scarabæolus hemisphæricus*. *Cochinelifera cochinilla*. *Coccus Americanus*. *Cochinelle*. *Coccus Indicus tinctorius*. Cochineal. The female of a species of insect called *Coccus cacti*, that is found on, and collected in South America, from the *Opuntia*, or Indian fig-tree. It possesses stimulating qualities, and is ordered by the College in the *tinctura cardamomi composita*, and *tinctura cinchonæ composita*; but, most probably, merely on account of the beautiful red colour which it imparts to them.

COCCYGE′US. (*Coccygeus*, sc. *musculus*; from κοκκυξ: because it is inserted into the coccyx.) *Ischio-cocigien* of Dumas. A muscle of the os coccygis, situated within the pelvis. It arises tendinous and fleshy, from the spinous process of the ischium, and covers the inside of the sacro-ischiatic ligament; from this narrow beginning it gradually increases to form a thin fleshy belly, interspersed with tendinous fibres. It is inserted into the extremity of the os sacrum, and nearly the whole length of the os coccygis, laterally. Its use is to support and move the os coccygis forwards, and to tie it more firmly to the sacrum.

CO′CCYGIS OS. (From κοκκυξ, the cuckoo, whose bill it is said to represent.) *Cauda*. *Ossis sacri acumen*. *Coccyx*. This bone is a small appendage to the point of the sacrum, terminating this inverted column with an acute point, and found in very different conditions in the several stages of life. In the child, it is merely cartilage, and we can find no point of bone: during youth, it is ossifying into distinct bones, which continue moveable upon each other till manhood; then the separate bones gradually unite with each other, so as to form one conical bone, with bulgings and marks of the pieces of which it was originally composed; but still the last bone continues to move upon the joint of the sacrum, till, in advanced years, it is at last firmly united; later in women than in men, with whom it is often fixed at twenty or twenty-five. It is not, like the os sacrum, flat, but of a roundish form, convex without, and concave inwards; forming with the sacrum the lowest part of the pelvis behind. It has no holes like the sacrum; has no communication with the spinal canal, and transmits no nerves; but points forwards to support the lower parts of the rectum; thus it contracts the lower opening of the pelvis, so as to support effectually the rectum, bladder, and womb; and yet continues so moveable in women, as to recede in time of labour, allowing the head of the child to pass.

CO′CCYX. (Κοκκυξ, the cuckoo.) See *Coccygis os*. Also the part in which the os coccygis is placed.

Co′chia. (From κοχαω, to turn or make round.) An antient name of some officinal pills.

Co'chineal. See *Coccus cacti.*

COCHLEA. (From κοχαζω, to turn round.) A cavity of the internal ear, resembling the shell of a snail, in which are observed, the *modiolus*, or *nucleus*, extending from its basis to the *apex*, the *scala tympani*, *scala vestibuli*, and *spiral lamina.*

Co'chlea terre'stris. See *Limax.*

COCHLEA'RE. (From *cochlea*, a cockle, whose shell its bowl represents.) A spoonful. In prescriptions it is sometimes abbreviated thus, *coch.* *Cochleare magnum*, is a table-spoon; *cochleare medium*, a dessert or pap spoon; and *cochleare minimum*, a tea-spoon.

COCHLEA'RIA. (From *cochleare*, a spoon; so called from its resemblance.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia.* Order, *Siliculosa.*

Cochlea'ria armora'cia. The systematic name of the horse-radish. *Raphanus rusticanus. Armoracia. Raphanus marinus. Raphanus sylvestris.* Horse-radish. The plant which affords this root is the *Cochlearia armoracia; foliis radicalibus lanceolatis crenatis, caulinis incisis*, of Linnæus. Horse-radish has long been received into the materia medica, and is also well known at our tables. "It affects the organs both of taste and smell with a quick penetrating pungency; nevertheless it contains in certain vessels a sweet juice, which sometimes exudes in little drops upon the surface. Its pungent matter is of a very volatile kind, being totally dissipated in drying, and carried off in evaporation, or distillation by water; as the pungency exhales, the sweet matter of the root becomes more sensible, though this also is, in a great measure, dissipated or destroyed. It impregnates both water and spirit, by infusion, or by distillation, very richly with its active matters. In distillation with water, it yields a small quantity of essential oil, exceedingly penetrating and pungent."

Dr. Cullen has mentioned every thing necessary to be known respecting the medicinal virtues of horse-radish, we shall therefore transcribe all that the ingenious professor has written on this subject. "The root of this plant only is employed; and it affords one of the most acrid substances of this order (*Siliquose*), and therefore proves a powerful stimulant, whether externally or internally employed. Externally, it readily inflames the skin, and proves a rubefacient that may be employed with advantage in palsy and rheumatism; and if its application be long continued, it produces blisters. Taken internally, it may be so managed as to relieve hoarseness, by acting on the fauces. Received into the stomach, it stimulates this, and promotes digestion: and therefore is properly employed as a condiment with our animal food. If it be infused in water, and a portion of this infusion be taken with a large draught of warm water, it readily proves emetic, and may either be employed by itself to excite vomiting, or to assist the operation of other emetics. Infused in water, and taken into the stomach, it proves stimulant to the nervous system, and is thereby useful in palsy, and, if employed in large quantity, it proves heating to the whole body; and thereby it proves often useful in chronic rheumatism, whether arising from scurvy or other causes. Bergius has given us a particular method of exhibiting this root, which is, by cutting it down, without bruising, into small pieces; and these, if swallowed without chewing, may be taken down in large quantities, to that of a table-spoonful. And the author alleges, that, in this way, taken in the morning for a month together, this root has been extremely useful in arthritic cases; which, however, I suppose to have been of the rheumatic kind. It would seem, in this manner employed, analogous to the use of unbruised mustard-seed; it gives out in the stomach its subtile volatile parts, that stimulate considerably without inflaming. The matter of horse-radish, like the same matter of the other siliquose plants carried into the blood-vessels, passes readily into the kidneys, and proves a powerful diuretic, and is therefore useful in dropsy; and we need not say, that, in this manner, by promoting both urine and perspiration, it has been long known as one of the most powerful antiscorbutics."

Cochlea'ria horte'nsis. Lemon scurvy-grass.

Cochlea'ria officina'lis. The systematic name of the lemon scurvy-grass. *Cochlearia hortensis.* This indigenous plant, *Cochlearia officinalis; foliis radicalibus cordato subrotundis, caulinis oblongis subsinuatis*, of Linnæus, is cultivated in gardens for its medicinal qualities. Its expressed juice has been long considered as the most effectual of the scorbutic plants.

Cocho'ne. (From κοχαω, to turn round.) Galen explains this to be the juncture of the ischium, near the seat or breech; whence, says he, all the adjacent parts about the seat are called by the same name. Hesychius says, that *cochone* is the part of the spine which is adjacent to the os sacrum.

COCKBURN, William, was born in the latter part of the 17th century. After being some years physician to the navy, he settled in London; and soon distinguished himself so much, that he was admitted into the College, as well as the Royal Society, and made physician to King William. He published a "Treatise on Sea Diseases," which was often reprinted, and translated into French and German. He referred the scurvy principally to the diet of seamen, and considered fresh provisions as the chief remedy for it. He wrote also on Alvine Fluxes, on Gonorrhœa, (which he contends may exist independent of syphilis,) and on the Human Œconomy; which latter publication was much noticed at the time, but is since superseded by more accurate treatises.

CO′COS. (So called from the Portuguese *coco*, or *coquen*, the three holes at the end of the cocoa-nut shell, giving it the resemblance of a monkey's head.) The name of a genus of plants in the Linnæan system. Class, *Monoecia*. Order, *Hexandria*. The cocoa-nut tree.

Co′cos nucife′ra. The systematic name of the plant, whose fruit is the cocoa-nut.

Co′cos butyra′cea. The systematic name of the plant which affords the palm oil, *Oleum palmæ*, which is produced chiefly from the fruit of the *Cocos butyracea; inermis, frondibus pennatis; foliolis simplicibus*, of Linnæus, by bruising and dissolving the kernels of the fruit in water, without the aid of heat, by which the oil is separated, and rises to the surface, and on being washed two or three times, is rendered fit for use. When brought into this country, it is of the consistence of an ointment, and of an orange-yellow colour, with little taste, and of a strong, though not disagreeable smell. Its use is confined to external applications in pains, tumours, and sprains; but it appears to possess very little, if any, advantage over other bland oils.

Co′ction. (From *coquo*, to boil.) Concoction. Digestion. In a medical sense, signifies that alteration, whatever it be, or however occasioned, which is made in the crude matter of a distemper, whereby it is either fitted for a discharge, or rendered harmless to the body. This is often brought about by nature; that is, by the vis vitæ, or the disposition or natural tendency of the matter itself, or else by proper remedies, which may so alter its bulk, figure, cohesion, or give it a particular determination, so as to prevent any farther ill effects, or drive it quite out of the body. And, that time of a disease wherein this action is performing, is called its state of coction.

Cocu′stu. The name for courbaril.

Codoce′le. (From κωδια, a bulb, and κηλη, a tumour.) A bubo.

Coda′ga pala. See *Nerium antidysentericum*.

Cœca′lis. (From *cœcum*, the blind gut, through which it runs.) A vein, being a branch from the concave side of the vena mesaraica.

Cœ′la. (From κοιλος, hollow.) The hollow pits above, and sometimes below the eyes. The hollow parts at the bottom of the feet.

Cœ′lia. (From κοιλος, hollow.) A cavity in any part of the body. The belly. The womb.

CŒ′LIAC A′RTERY. (*Cœliacus*, belonging to the belly; from κοιλια, the belly.) *Arteria cœliaca*. The first branch given off from the aorta in the cavity of the abdomen. It sends branches to the diaphragm, stomach, liver, pylorus, duodenum, omentum, and spleen.

CŒ′LIAC PA′SSION. (*Cœliacus*, belonging to the belly; from κοιλια, the belly.) *Cœlica chylosa*. *Cœlica lactea*. There are very great differences among physicians concerning the nature of this disease. Sauvages says it is a chronic flux, in which the aliment is discharged half digested. Dr. Cullen considers it as a species of diarrhœa, and mentions it in his third and fourth species, under the terms mucosa, chylosa, lactea; making the purulenta only symptomatic. See *Diarrhœa*. It is attended with great pains in the stomach, resembling the pricking of pins; rumbling and flatus in the intestines; white stools, because deprived of bile; while the patient becomes weak and lean.

Cœlo′ma. (From κοιλος, hollow.) An ulcer in the tunica cornea of the eye.

Cœlosto′mia. (From κοιλος, hollow, and ϛομα, the mouth.) A defect in speaking, when a person's speech is obscured by sounding as if his voice proceeded from a cavern.

Cœnolo′gia. (From κοινος, common, and λογος, discourse.) A consultation, or common consideration of a disease, by two or more physicians.

Cœno′tes. (From κοινος, common.) The physicians of the methodic sect asserted that all diseases arose from relaxation, stricture, or a mixture of both. These were called *cœnotes*, viz. what diseases have in common.

Cœru′leus la′pis. The sulphate of copper. See *Cupri sulphas*.

Cœ′te. (From κειμαι, to lie down.) A bed, or couch, for a sick person.

CO′FFEA. (From *kofuah*, a mixing together, Hebr.; so called from the pleasant potation which is made from its berry: others assert that the true name is *Caffè*, from *Caffa*, a province in South America, where the tree grows spontaneously in great abundance.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Monogynia*. The coffee-tree.

Co′ffea Ara′bica. The plant which affords coffee. *Jasminum Arabicum*. *Choava*. Coffee is the seeds of the *Coffea; floribus quinquefidis, dispermis*, of Linnæus. The coffee-tree is cultivated in Arabia, Persia, the East Indies, the Isle of Bourbon, and several parts of America. Good Turkey coffee is by far the most salutary of all liquors drunk at meal-time. It possesses nervine and adstringent qualities, and may be drunk with advantage at all times, except when there is bile in the stomach. It is said to be a good antidote against an overdose of opium, and to relieve obstinate spasmodic asthmas. For the latter purpose, the coffee ought to be of the best Mocco, newly burnt, and made very strong, immediately after grinding it. Sir John Pringle commonly ordered one ounce for a dose; which is to be repeated fresh, after the interval of a quarter or half an hour; and which he directed to be taken without milk or sugar.

If coffee be drunk warm within an hour after dinner it is of singular use to those who have head-ache, from weakness in the stomach, contracted by sedentary habits, close attention, or accidental drunkenness. It is of service when the digestion is weak; and persons afflicted with the sick head-ache are much benefited by its use, in some instances, though this effect is by no means uniform. Coffee is often imitated by roasting rye with a few almonds.

CO'GAN, William, was born in Somersetshire, about the middle of the 16th century. He studied, and took the degree of bachelor in medicine at Oxford; soon after which he was appointed master of the school at Manchester, where he also practised in his profession till his death in 1607. He published a curious book, abounding in classical quotations, entitled "The Haven of Health," in which he strongly recommends temperance and exercise. There is added an account of the sweating sickness; and of a remarkable disorder, which prevailed at Oxford in July and August 1575, before he left it, by which he states that in thirty-seven days, "there died 510 persons, all men and no women."

COHE'SION. (From *con*, and *hæreo*, to stick together.) *Vis cohæsionis*. *Vis adhæsionis*. *Vis attractionis*. That force in the particles of matter whereby they are connected in such a way that they resist any attempt towards their removal or separation. It is a species of attraction. See *Attraction*.

Cohoba'tion. (A term invented by Paracelsus.) *Cohobatio*. *Cohobium*. *Cohoph*. The antient chemists use this term to signify the distillation of a fluid poured afresh upon a substance of the same kind as that upon which it was before distilled, and repeating this operation several times, to make it more efficacious. For this purpose, the vessel called pelican was employed.

Co'hol. (*Cohol*, Heb.) Castellus says this word is used in Avicenna, to express dry collyria for the eyes, in fine powder.

Coi'lima. (From κοιλια, the bowels.) A sudden swelling of the belly from wind.

Coilosto'mia. (From κοιλος, hollow, and ϛομα, the mouth.) A defect of speaking, from the palate, or through the nose.

Coindica'ntia. (From *con*, and *indico*, to indicate.) Signs, or symptoms, are called coindicant, when, besides the usual incidental appearances, there occur others, as age, habit, season, &c.

Coi'ra. A name for catechu.

COITER, Volcher, was born at Groningen in 1534. After studying at the different universities in Italy, he attended as physician to the French army during one campaign, that he might have more opportunity for investigating human anatomy. He then settled at Nuremberg, where he continued till his death in 1576. He made considerable improvements in anatomy and surgery. He found that the brain had a motion communicated to it by the arteries; and that in some animals the organ might be removed without destroying life. He first described the corpora lutea in the ovaria; and noticed the order in which the parts of the chick are evolved. He described the frontal sinuses, and the organ of hearing, more accurately than any preceding author. He pointed out two muscles which depress the eye-brows, and two which perform the same office to the lips. He observed, that injuries to the brain are more dangerous when the dura mater remains entire; and therefore he boldly divided that membrane. He was accustomed also to pare down fungi arising from the brain. He published good plates of the cartilages, of the fœtal skeleton, and of those of various animals, &c.

CO'ITUS. (From *coeo*, to go together.) The conjunction of the male and female in the act of procreation.

Co'la. (From κωλον, a joint.) The joints.

Colato'ria la'ctea. Astruc says they were formerly called glands, and are situated in the third and internal tunic of the uterus, and, that they are vesiculo-vascular bodies.

Colato'rium. (From *colo*, to strain.) A strainer of any kind.

Colatu'ra. (From *colo*, to strain.) A filtered or strained liquor.

COLBATCH, John, was born in the latter part of the 17th century. He practised in London, first as a surgeon and apothecary, afterwards as a physician, and had considerable repute. He published several works: the first was "A New Light of Chirurgery," condemning the use of tents, and the injection of acrid substances into wounds; then a treatise, in which most diseases are ascribed to alkalescency, and acids strongly recommended; this in a subsequent publication he applied particularly to the gout; lastly, he highly extolled the misletoe as a remedy for epilepsy and other nervous diseases.

Colcaquahui'tl. An American plant, commended in palsies and uterine disorders, according to Ray.

COLCESTRE'NSIS A'QUA. Colchester water. This mineral water is of the bitter purging kind, similar to that of Epsom, but not so strong.

CO'LCHICUM. (From *Colchis*, a city of Armenia, where this plant is supposed to have been common.) 1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*. Order, *Trigynia*. Meadow-saffron.

2. The pharmacopœial name of the meadow-saffron. See *Colchicum autumnale.*

Co'lchicum autumna'le. The systematic name of the common meadow-saffron. *Colchicum; foliis planis lanceolatis erectis,* of Linnæus. A native of England. The sensible qualities of the fresh root are very various, according to the place of growth and season of the year. In autumn it is almost inert, but in the beginning of summer highly acrid: hence some have found it to be a corrosive poison, whilst others have eaten it in considerable quantity, without experiencing any effect. When it is possessed of acrimony, this is of the same nature with that of garlic and some other plants, and is entirely destroyed by drying. The German physicians have celebrated its virtues as a diuretic, in hydrothorax and other dropsies; and in France it continues to be a favourite remedy; but it is, nevertheless, in this country unsuccessful, or at best a very uncertain remedy. The expressed juice is used, in Alsace, to destroy vermin in the heads of children. The officinal preparations of colchicum are, Syr. Colch. Autum. Edin. Pharm. The oxymel colchici of the former London pharmacopœia is now omitted, and the acetum colchici ordered in its room; as the honey may easily be added extemporaneously, if it be thought requisite. The following is the formula of the present London Pharm. for preparing the acetum colchici, or vinegar of meadow-saffron: "Take of fresh meadow-saffron root sliced, an ounce; acetic acid, a pint; proof spirit, a fluid-ounce. Macerate the meadow-saffron root in the acid, in a covered glass vessel, for twenty-four hours; then press out the liquor and set it by, that the feculencies may subside; lastly, add the spirit to the clear liquor." The dose is from ʒss to ʒjss.

Co'lchicum illy'ricum. The plant supposed to afford the *hermodactyls.* See *Hermodactylus.*

Co'lchicum Zeyla'nicum. See *Zedoaria.*

Co'lcothar vitri'oli. *Chalcitis.* The remains of calcined martial vitriol.

COLD. A privation of heat. It is nothing positive, but somewhat of the negative kind. The human body contains within itself, as long as it is living, a principle of warmth: if any other body, being in contact with it, abstracts the heat with unusual rapidity, it is said to be cold; but if it carries off the heat more slowly than usual, or even communicates heat to our body, it is said to be hot.

A cold is a popular name also for a catarrh. See *Catarrhus.*

COLD AFFUSION. A process formerly sometimes practised by physicians, but lately introduced by Dr. Currie, of Liverpool, in the treatment of typhus fever, and which appears to possess an uniformity of success, which we look for in vain in almost any other branch of medical practice. The remedy consists merely in placing the patient in a bathing-tub, or other convenient vessel, and pouring a pailful of cold water upon his body; after which he is wiped dry, and again put to bed. It should be noted,

First, That it is the *low contagious fever* in which the cold affusion is to be employed. The first symptoms of which are a dull head-ache, with restlessness and shivering; pains in the back, and all over the body, the tongue foul, with great prostration of strength; the head-ache becoming more acute, the heat of the body, by the thermometer, 102° to 105° or more; general restlessness, increasing to delirium, particularly in the night.

Secondly, That it is *in the early stage of the disease* we must employ the remedy; and generally *in the state of the greatest heat and exacerbation.*

Thirdly, It is *affusion, not immersion,* that must be employed.

Since the first publication of Dr. Currie's work, the practice of affusion has been extended throughout England; and its efficacy has been established in some stages of the disease, from which the author had originally proscribed the practice of it. One of the cautionary injunctions which had been given for the affusion of cold water in fever, was, *never to employ it in cases where the patient had a sense of chilliness upon him,* even if the thermometer, applied to the trunk of the body, indicated a preternatural degree of heat. In his last edition of Reports, however, Dr. Currie has given the particulars of a case of this description, in which the cold affusion was so managed as to produce a successful event.

In fevers *arising from, or accompanied by, topical inflammation,* his experience does not justify the use of cold affusion; though, in a great variety of these cases, the warm affusion may be used with advantage. "And," says he, "though I have used the cold affusion in some instances, so late as the twelfth or fourteenth day of contagious fever, with safety and success, yet it can only be employed, at this advanced period, in the instances in which the heat keeps up steadily above the natural standard, and the respiration continues free. In such cases, I have seen it appease agitation and restlessness, dissipate delirium, and, as it were, snatch the patient from impending dissolution. But it is in the *early stages* of fever (let me again repeat) that it ought always to be employed, if possible; and where, without any regard to the heat of the patient, it is had recourse to in the last stage of fever, after every other remedy has failed, and the case appears desperate, (of which I have heard several instances,) can it appear surprising that the issue should sometimes be unfavourable?"

Numerous communications from various practitioners, in the West and East Indies, in Egypt and America, also show the efficacy of affusion in the raging fevers of hot countries.

COLE, William, studied at Oxford, and took his degree there in 1666. After practising some time at Bristol, he came to London, and distinguished himself by several publications on physiology and medicine, which however are too theoretical. The principal are on animal secretion, on apoplexy, on the cause of fever, on insensible perspiration, &c. He published also a case of epilepsy, cured, in his opinion, by the misletoe.

Co′les. (From καυλος, a stalk.) *Colis.* The penis.

Colewort. See *Brassica.*

Co′li de′xtrum ligame′ntum. Where the mesentery changes its name for that of mesocolon, (near the extremity of the ileum,) the particular lamina, which is turned to the right side, forms a small transverse fold, which is thus named.

Co′li sini′strum ligame′ntum. It is a contraction of the mesocolon, a little below the left kidney.

CO′LICA. (From κωλον, colon, the name of one of the intestines.) The colic. The appellation of colic is commonly given to all pains in the abdomen, almost indiscriminately; but, from the different causes and circumstances of this disorder, it is differently denominated. When the pain is accompanied with a vomiting of bile, or with obstinate costiveness, it is called a *bilious colic:* if flatus causes the pain, that is, if attended with temporary distention, relieved by the discharge of wind, it takes the name of *flatulent* or *windy colic;* when accompanied with heat and inflammation, it takes the name of *inflammatory colic*, or *enteritis.* When this disease arises to a violent height, and is attended with obstinate costiveness, and an evacuation of fæces by the mouth, it is called *passio iliaca*, or iliac passion.

Dr. Cullen places this genus of disease in the class *neuroses*, and order *spasmi;* and defines it pain of the abdomen, particularly round the umbilicus, attended with vomiting and costiveness. He enumerates seven species.

1. *Colica spasmodica*, with retraction of the navel, and spasm of the muscles of the belly.

2. *Colica pictonum.* This is called from the place where it is endemial, the Poictou, the Surinam, the Devonshire colic; from its victims, the plumbers' and the painters' colic; from its symptoms, the dry belly-ache, the nervous and spasmodic colic. It has been attributed to the poison of lead, and this is undoubtedly the cause, when it occurs to glaziers, painters, and those employed in lead works; but, though this is one, it is by no means the only cause. In Devonshire, it certainly more often arises from the early cyder, made of harsh, unripe fruit, and in the West Indies from new rum. The characteristics of this disease are, obstinate costiveness, with a vomiting of an acrid or porraceous bile, pains about the region of the navel, shooting from thence to each side with excessive violence, strong convulsive spasms in the intestines, and a tendency to a paralysis of the extremities. It is occasioned by a long-continued costiveness; by an accumulation of acrid bile; by cold applied either to the extremities, or to the belly itself; by a free use of unripe fruits, and by great irregularity in the mode of living. From its occurring frequently in Devonshire, and other cyder counties, it has been supposed to arise from an impregnation of lead received into the stomach; but this seems to be a mistake, as it is a very prevalent disease in the West Indies likewise, where no cyder is made, and where there is only a very small quantity of lead in the mills employed to extract the juice from the sugar-canes. One or other of the causes just enumerated, may justly be said always to give rise to this species of colic.

The disease comes on gradually, with a pain at the pit of the stomach, extending downwards to the intestines, accompanied with eructations, slight sickness at the stomach, thirst, anxiety, obstinate costiveness, and a quick contracted pulse. After a short time, the pains increase considerably in violence; the whole region of the belly is highly painful to the touch; the muscles of the abdomen are contracted into hard irregular knots or lumps; the intestines themselves exhibit symptoms of violent spasm, insomuch that a glyster can hardly be injected, from the powerful contraction of the sphincter ani; and there is constant restlessness, with a frequent vomiting of an acrid or porraceous matter, but more particularly after taking either food or medicine.

Upon a farther increase of the symptoms, or their not being quickly alleviated, the spasms become more frequent, as well as violent; the costiveness proves invincible, and an inflammation of the intestines ensues, which soon destroys the patient by gangrene. In an advanced stage of the disease, it is no uncommon occurrence for dysuria to take place, in a very high degree.

The dry belly-ache is always attended with some degree of danger; but which is ever in proportion to the violence of the symptoms, and the duration of the disease. Even when it does not prove fatal, it is too apt to terminate in palsy, and to leave behind it contractions of the hands and feet, with an inability in their muscles to perform their office; and in this miserable state of existence, the patient lingers out many wretched years.

Dissections of this disease usually show the same morbid appearances as in common colic, only in a much higher degree; namely, irregular contractions and distention of the intestines, often with marks of inflammation.

3. *Colica stercorea*, which happens from obstinate and long-continued costiveness.

4. *Colica accidentalis*, called also cholera sicca, from acrid undigested matters.

5. *Colica meconialis*, in infants, from a retention of meconium.

6. *Colica callosa*, with a sensation of a stricture in some part of the colon, and frequently of previous flatulence, gradually passing off; the habit costive, or fæces liquid, and in small quantity.

7. *Colica calculosa*, from calculi formed in the intestines, attended with a fixed hardness in some part of the abdomen. It is distinguished by the previous discharge of calculi.

8. *Colica flatulenta* may be added to these species. It is distinguished by a sudden fulness, with pain and constipation, relieved by a discharge of wind from the mouth, or anus.

The colic is distinguished from inflammation of the intestines by the pain being *wringing*, and not of a burning kind; by the *spasmodic contraction* of the abdominal muscles; by the *absence* or *trifling* degree of fever; by the *state* of the pulse, and by the *diminution* of pain upon pressure, which increases it in enteritis.

The flatulent and inflammatory colic are thus distinguished from each other: — In the flatulent colic, the pain comes on by fits, flies from one part of the bowels to another, and is much abated by a discharge of wind, either upwards or downwards; but in the inflammatory colic the pain remains equable, and fixed and settled in one spot; the vomitings are severe, and frequently bilious; the belly is obstinately bound, and the pulse quick and feverish.

The colic should be distinguished from a fit of the gravel; stones passing through the ureters; rheumatic pains in the muscles of the belly; a beginning dysentery; the blind piles; and from a stone passing through the gall-duct. Gravel in the kidneys produces often colic pains, not easily distinguishable; but when stones pass through the ureters, the testicle on that side is often retracted, the leg is benumbed, a pain shoots down the inside of the thigh; symptoms occasioned by the stone passing through the ureter over the spermatic chord, or the sacro-sciatic nerve. Rheumatic pains in the muscles of the belly rarely affect so accurately the umbilical region, but dart in various directions, to the chest, or to the pelvis, and are attended with soreness, not confined to the abdomen. A beginning dysentery differs little from colic. The pain from the blind piles is confined to the rectum: and that from a stone in the gall-duct, is felt in the pit of the stomach, occasionally shooting through the body to the back.

The treatment of this disease must vary according to its form: but the leading indications are, 1. To obviate inflammation. 2. To relax the spasm, and relieve the pain attending. 3. To remove local irritation, especially by evacuating the alvine contents. 4. By various prophylactic measures to guard against a relapse. — 1. The chief danger arising from inflammation supervening, it may be prudent to anticipate this, where the habit and strength will allow, by taking away an adequate quantity of blood from the arm, or more generally by leeches to the abdomen, but especially where any sign of inflammation appears, this plan becomes necessary, followed by a hot bath, or fomentations, a blister to the abdomen, &c. as detailed under *enteritis*. 2. The means already noticed may serve to relax spasm also, though not requisite in slight cases, besides the various antispasmodic remedies, as æther, assafœtida, &c.; likewise aromatics, or spirituous liquors, will often by their stimulus on the stomach afford relief in flatulent colic, though their use is sometimes hurtful; but by far the most powerful remedy is opium in adequate quantity, which is best regulated in severe attacks, by giving divided doses at short intervals till ease is obtained. 3. Local irritation may sometimes be relieved by chemical remedies, as antacids, particularly magnesia, &c.; but for the most part the evacuation of the intestines should be attempted, when the pain is relieved. To prepare for this calomel, may be given in conjunction with the opium, and when the patient has been some time at ease, this may be followed up by castor oil, sulphate of magnesia, or other mild laxative, repeated till the desired effect be produced; or where these do not presently operate, some more active cathartics, as the compound extract of colocynth, jalap, &c. should be tried. If the stomach be irritable, the effervescing saline draught may enable it to retain them; and clysters will often assist the articles taken by the mouth, particularly where there are indurated fæces. In very obstinate cases, an injection of tobacco smoke has often succeeded in procuring evacuations: also putting the feet for some time into cold water, or pouring this on the abdomen and lower extremities. Sometimes it has been necessary to remove fœcal accumulations mechanically per anum. 4. The great liability of this complaint to return renders it necessary for some time after carefully to regulate the diet, to attend to the state of the bowels, as well as of the liver, to avoid the several causes, especially cold, maintaining the function of the skin by suitable clothing, exercise, &c. In the colica pictonum, stimulant aperients, as the peruvian balsam, mustard, &c. steadily persisted in, will mostly effect a complete cure; and mercury has been by some highly extolled; by others, astringents, especially alum, though certainly somewhat objectionable, as liable to confine the bowels.

Co′lica accidenta′lis. Colic from crudities in the bowels.

Co′lica arte′ria sini′stra. The lower mesenteric artery.

Co′lica arte′ria supe′rior. The upper mesenteric artery.

Co′lica bilio′sa. Colic from excess of bile.

Co′lica calculo′sa. Colic from stony matters in the intestines.

Co′lica callo′sa. Colic from hardened and obstinate strictures.

Co′lica Damnonio′rum. Colic peculiar to Devonshire. See *Colica.*

Co′lica febrico′sa. Colic with fever.

Co′lica flatule′nta. Colic from wind.

Co′lica gravida′rum. Colic in pregnant women.

Co′lica hyste′rica. Hysteric colic.

Co′lica lacta′ntium. Colic peculiar to nurses.

Co′lica Lappo′nica. Colic peculiar to Laplanders.

Co′lica meconia′lis. Colic from meconium in infants.

Co′lica mesente′rica. Colic from diseased mesentery.

Co′lica nervo′sa. The nervous colic.

Co′lica pancrea′tica. Colic from diseased pancreas.

Co′lica phlogi′stica. Colic with inflammation.

Co′lica pi′ctonum. See *Colica.*

Co′lica pituito′sa. The spasmodic colic.

Co′lica pletho′rica. The inflammatory colic.

Co′lica plumbario′rum. The colic of lead-workers.

Co′lica pulsa′tilis. The inflammatory colic.

Co′lica saturni′na. The Devonshire colic. See *Colica.*

Co′lica scirrho′sa. The colic from scirrhous tumours.

Co′lica spasmo′dica. The spasmodic colic.

Co′lica sterco′rea. Colic from retained fæces.

Co′lica ve′na. A branch of the upper mesenteric vein.

Co′lica ve′na re′cta. The vein of the colon.

Co′lica vermino′sa. The colic from worms.

Co′lice. The colic.

Colifo′rmis. (From *cola*, a strainer, and *forma*, a likeness; so called from its having many perforations, like a strainer.) *Coliforme os.* A name formerly given to the os cribrosum.

Coli′phium. (From *κωλον*, a limb, and *ιφι*, strongly.) A kind of bread given to wrestlers. It was made of flour and bran together, and was thought to make men athletic.

Co′lis. The same as coles.

Colla′psus. (From *collabor*, to shrink down.) A wasting or shrinking of the body, or strength.

Collate′nna. A specific vulnerary.

Collatera′les. So Spigelius calls the erectores penis, from their collateral order of fibres.

Colle′tica. (From *κολλὰ*, glue.) Conglutinating medicines.

Colli′ciæ. (From *colligo*, to collect.) The union of the ducts, which convey the humours of the eyes from the puncta lachrymalia to the cavity of the nose.

Colli′culum. (Dim. of *collis*, a hill.) The nympha, or prominency, without the vagina of women.

Colliga′men. (From *colligo*, to tie together.) A ligament.

COLLINS, Samuel, was born in the early part of the 17th century. After studying at Cambridge and Oxford, he went to the Russian court as physician, and continued there nine years. On his return, he was made Fellow of the College of Physicians in London. He afterwards published a history of the Court of Russia, and in 1685 a system of anatomy, treating of the body of man, animals, and plants, with numerous plates. The comparative anatomy, to which Dr. Tyson greatly contributed, was much admired, though now superseded by other publications.

Colliquame′ntum. (From *colliqueo*, to melt.) A term first made use of by Dr. Harvey, in his application of it to the first rudiments of an embryo in generation.

COLLI′QUATIVE. (From *colliqueo*, to melt.) Any excessive evacuation is so called which melts down, as it were, the strength of the body: hence colliquative perspiration, colliquative diarrhœa, &c.

Colli′sio. (From *collido*, to beat together.) A contusion.

Co′llix. (From *κολον*, food.) A troch, or lozenge.

Collobo′ma. (From *κολλαω*, to glue together.) The growing together of the eye-lids.

Collo′des. (From *κολλα*, glue.) Glutinous.

Co′llum. (From *κωλον*, a member, as being one of the chief; or dim. of *columna*, as being the pillar and support of the head.) The neck.

COLLUTO′RIUM. (From *colluo*, to wash.) A gargarism or wash for the mouth.

COLLU′VIES. (From *colluo*, to cleanse.) Filth. Excrement. The discharge from an old ulcer.

Co′llyris. (*Κολλυρις*, a little round cake;

so called from its likeness to a cake.) A bump, or knob, which rises after a blow.

COLLY′RIUM. (From κωλυω, to check, and ρους, a defluxion; because it stops the defluxion.) Any medicine was formerly so called which was applied with that intention. The term is now only given to fluid applications for the eyes, or eye-waters.

Colobo′ma. (From κολλαω, to glue together.) The growing together of the eye-lids: also the want of a particular member of the body.

Colobo′mata. In Celsus this word is expressed by curta. Both the words signify a deficiency in some part of the body, particularly the ears, lips, or alæ of the nostrils.

Coloca′sia. (From κολον, food, and καζω, to adorn; so called from its use as a food, and the custom of wearing its flowers in wreaths.) The faba Ægyptia.

COLOCY′NTHIS. (From κωλον, the colon, and κινεω, to move; because of its great purging powers.) See *Cucumis colocynthis.*

Colo′mbo. See *Calumba.*

CO′LON. (*Colon, li,* neut. Κωλον, quasi κοιλον; from κοιλος, hollow; so called from its capacity, or from its generally being found empty, and full of wind in dissection.) The greater portion of the large intestine is so called. It proceeds towards the liver, by the name of the *ascending portion of the colon;* and having reached the liver, forms a *transverse arch* across to the other side. The colon then descends, forming what is termed its *sigmoid flexure,* into the pelvis, where the gut is called rectum. See *Intestines.*

Colopho′nia. (Κολοφωνια, the city from whence it was first brought.) *Resina nigra.* The black resin which remains in the retort, after distilling the common resin with a strong fire. Paracelsus seems to mean by it what is now prescribed by the name of *terebinthina cocta:* but the antients, and particularly Galen, seemed to understand by it a soft kind of mastich, from *Chio,* probably the same as our *Chio* turpentine.

Colo′strum. (From κολον, food, or κολλωμαι, to agglutinate; so called, either because it is the first food of the young, or from its being at that time peculiarly glutinous.) The first milk in the breasts after delivery, according to some authors; but Bartholine applies it to an emulsion made by the solution of turpentine with the yolk of an egg.

COLOT, Germain, a French surgeon of the 15th century, appears to have been the first of the profession who practised Lithotomy, that operation having been previously in the hands of itinerant practitioners. He acquired great celebrity by his skill, and was much in favour with Lewis IX., who granted him a pension. Several of his descendants in succession enjoyed great reputation as lithotomists.

COLOT, Francis, the last of them, left a treatise, published in 1727, describing the method of operating with the greater apparatus, the invention whereof he ascribes to John de Romanis, an Italian physician, about two centuries before. But this has long been superseded by the lesser apparatus, which Mr. Sharp attributes to another French surgeon, Mons. Foubert.

Colotoi′des. (From κωλωτης, a lizard, and ειδος, likeness.) Variegated like the skin of a lizard. Hippocrates applied it to the excrements.

Coloqui′ntida. See *Cucumis colocynthis.*

Colpoce′le. (From κολπος, the vagina, and κηλη, a tumour.) A hernia forced into the vagina.

Colpopto′sis. (From κολπος, the vagina, and ϖιπτω, to fall down.) A bearing down of the vagina.

Colt's-foot. See *Tussilago.*

CO′LUBER. (*Quod colit umbram,* because it delightest in the shade.) A genus of animals in the Linnæan arrangement, of which there are many species.

Co′luber be′rus. The systematic name of the viper. *Vipera.* This viviparous reptile, *Coluber berus* of Linnæus, possesses the power of forming a poisonous fluid in little bags near its teeth. The flesh is perfectly innocent, and often taken by the common people against the king's evil, and a variety of disorders of the skin. Experience evinces it to be an inefficacious substance.

Colubri′na virginia′na. See *Aristolochia Serpentaria.*

Colubri′num li′gnum. (*Colubrinus,* from *coluber;* so called from the snake-like contortions of its roots.) This species of snake-wood is brought from America. It is solid, ponderous, acrid, extremely bitter, and inodorous; its bark is of a ferruginous colour, covered with cineritious spots.

Co′lumbine. See *Aquilegia.*

Colu′mba. See *Calumba.*

Columbo′be. See *Calumba.*

Colume′lla. (Dim. of *columna,* a column.) See *Uvula,* and *Clitoris.*

COLU′MBIUM. Mr. Hatchett describes the ore from which this metal is obtained, as being of a dark brownish-grey externally, and more inclining to an iron-grey internally; the longitudinal fracture, he found, lamellated; and the cross fracture had a fine grain. Its lustre was vitreous, slightly inclining, in some parts, to metallic; moderately hard and very brittle. The colour of the streak, or powder, was dark chocolate-brown. The particles were not obedient to the magnet. Its specific gravity, at a temperature of 65° Fahr., Mr. Hatchett found to be 5.918.

A series of accurate experiments, made by its discoverer, prove that this ore consists of iron, combined with a new metallic acid, which constitutes more than three-fourths of the whole.

The smallness of the quantity Mr. Hatchett had to operate upon, has hitherto prevented us from seeing the metal in its metallic state; but the accuracy with which the properties of its acid have been investigated, leave no doubt of its being different from any of the acidifiable metals hitherto known.

Columella'ris. (From *columella*, a little column.) A name of the dens caninus.

COLU'MNA. A column, or pillar. Many parts of the body, which in their shape or office resemble columns, are so named; as columnæ carneæ, &c.

Colu'mna na'si. The lowest and fleshy part of the nose, which forms a part of the septum.

Colu'mna o'ris. A name for the uvula.

Colu'mnæ ca'rneæ. Columnæ cordis. See *Heart.*

Colu'rium. (*Παρα το κολλᾳν τον ρουν:* because it prevents a defluxion.) A tent to thrust into a sore, to prevent a defluxion of humours.

CO'MA. (From *κω*, or *κεω*, to lie down.) A propensity to sleep. This word antiently meant any total suppression of the powers of sense; but now it means a lethargic drowsiness. The coma vigil is a disease where the patients are continually inclined to sleep, but cannot.

Co'ma somnole'ntum. Is when the patient continues in a profound sleep; and, when awakened, immediately relapses, without being able to keep open his eyes.

CO'MATA. (*Κωματα:* from *coma.*) A diminution of the powers of voluntary motion, with sleep, or the senses impaired. It is an order of the class *neuroses* of Cullen's Nosology.

COMATOSE. Having a strong propensity to sleep.

COMBU'STIO. (From *comburo,* to burn.) A burn, or scald.

COMBUSTION. (From *comburo,* to burn.) Burning. Among the various operations of chemistry, none acts a more conspicuous part than combustion; and in proportion to its utility in the science, the necessity of thoroughly investigating its nature and mode of action, becomes more obvious to the philosophical chemist.

Lavoisier's Theory of Combustion.

Lavoisier's theory of combustion is founded upon the absorption of oxygen by a combustible body.

Taking this for granted, it follows that combustion is only the play of affinity between oxygen, the matter of heat, and a combustible body.

When an *incombustible* body (a brick for instance) is heated, it undergoes no change, except an augmentation of bulk and temperature; and when left to itself, it soon regains its former state. But when a *combustible* body is heated to a certain degree, in the open air, it becomes on a sudden intensely hot, and at last emits a copious stream of caloric and light to the surrounding bodies. During this emission, the burning body gradually wastes away. It either disappears entirely, or its physical properties become totally altered. The principal change it suffers, is that of being no longer capable of combustion. If either of these phenomena, namely, the emission of heat and light, and the waste of substance, be wanting, we do not say that a body is undergoing combustion, or that it is burning. It follows, therefore, that every theory of combustion ought to explain the following facts:

1. Why a burning body is consumed, and its individuality destroyed.

2. Why, during the progress of this alteration, heat and light are emitted.

For the elucidation of these objects, Lavoisier's theory has laid down the following laws:

1. Combustion cannot take place without the presence of oxygen, and is more rapid in proportion to the quantity of this agent, in contact with the inflamed body.

2. In every act of combustion, the oxygen present is consumed.

3. The weight of the products of every body after combustion, corresponds with the weight of the body before combustion, *plus* that of the oxygen consumed.

4. The oxygen absorbed by the combustible body may be recovered from the compound formed, and the weight regained will be equal to the weight which disappeared during the combustion.

5. In every instance of combustion, light and heat, or fire, are liberated.

6. In a limited quantity of air, only a certain quantity of the combustible body can be burnt.

7. The air, wherein a body has been burnt, is rendered unfit for continuing combustion, or supporting animal life.

Though every case of combustion requires that light and heat should be evolved, yet this process proceeds very differently in different circumstances; hence the terms *ignition,* or glowing heat; *inflammation,* or accension; and *detonation,* or explosion.

Ignition takes place when the combustible body is not in an aëriform state.

Charcoal, pyrophorus, &c. furnish instances of this kind.

It seems as if the phenomenon of glowing was peculiar to those bodies which require a considerable quantity of caloric, to become converted into the gaseous state.

The disengagement of caloric and light is rendered more evident to the senses in the act of

Inflammation, or accension. Here the combustible substances are more easily converted into an elastic or aëriform state.

Flame, therefore, consists of the inflammable matter in the act of combustion in the gaseous state. When all circumstances are favourable to the complete combustion of the products, the flame is perfect; if this is not the case, part of the combustible body, capable of being converted into the gaseous state, passes through the luminous flame unburnt, and exhibits the appearance of smoke. Soot, therefore, always indicates an imperfect combustion. Hence a common lamp smokes, an Argand's lamp yields no smoke.

This degree of combustion is very accurately exemplified in the

Flame of Candles. — When a candle is first lighted, which must be done by the application of actual flame, a degree of heat is given to the wick, sufficient to destroy the affinity of its constituent parts; part of the tallow is instantly melted, volatilized, and burnt. As this is destroyed by combustion, another portion melts, rises, and supplies its place, and undergoes a like change. In this way combustion is maintained. The tallow is liquified as it comes into the vicinity of the flame, and is, by the capillary attraction of the wick, drawn up to supply the place of what is burnt; the unmelted tallow, by this means, forms a kind of cup.

The congeries of capillary tubes which form the wick is black, because the charcoal of the cotton becomes predominant, the circum-ambient air is defended by the flame from oxidizing it; it therefore remains, for a considerable time, in its natural state; but when the wick, by the continual consumption of tallow, becomes too long to support itself in a perpendicular position, its upper extremity projects nearly out of the cone of the flame, and there forms a support for an accumulation of soot, which is produced by the imperfect combustion. A candle, in this situation, affords scarcely one-tenth of the light it can otherwise give, and tallow candles, on this account, require continual snuffing.

But if the candle be made of wax, the wick does not long occupy its place in the middle of the flame; its thinness makes it bend on one side, when its length is too great for its vertical position; its extremity comes then into contact with the air, and is completely burnt, or decomposed, except so much of it as is defended by the continual afflux of the melted wax. This small wick, therefore, performs the office of snuffing itself. The difficult fusibility of wax enables us to use a thinner wick for it than can be used for tallow, which is more fusible. But wax being a substance which contains much more oxygen than tallow, or oil, the light it affords is not so luminous.

Detonation is an instantaneous combustion, accompanied with a loud report; it takes place in general when the compounds resulting from the union of two or more bodies, occupy much more or less space than the substances did before their union; a great impulse is therefore given to the surrounding air, or else a vacuum is formed, and the air rushing in from all sides to fill it up is the cause of the report.

A mixture of oxygen and hydrogen gases detonates very loud. Gunpowder, fulminating gold, silver, and mercury; oxygenated muriate of potash; and various other explosive compounds, are capable of producing very loud detonations.

With respect to the disengagement of light and caloric.

By the older chemists, it was universally supposed that the light and heat emitted during combustion, proceeded from the inflammable body; and this opinion would indeed appear unquestionable, while the composition of the atmosphere was imperfectly known. The burning body appeared luminous and felt hot, and no other agent was supposed to be concerned; the conclusion that the light and heat were evolved from the burning substance, was, therefore, unavoidable. But when the nature of the atmosphere was ascertained, and when it became evident that part of the air was absorbed during combustion, the former conclusion fell to the ground; for when two bodies exert a mutual action on each other, it becomes *à priori* equally probable that the products may be derived from either of them; consequently, the light and heat evolved might proceed either from the one or the other. Whether they proceed from the atmosphere, or from the combustible body, they must be separated at the part where the combination takes place; that is, upon the surface of the burning body itself; and consequently it appeared luminous and heated, while the air being invisible escaped observation.

When the laws of heat became known, at least when it was ascertained that bodies contain at the same temperature, and in equal quantities, either of mass or bulk, unequal quantities of heat, the conclusion became probable, that the caloric evolved in combustion proceeded rather from the oxygen gas of the atmosphere, than from the combustible body; since the former contains a much larger quantity than the latter. The caloric evolved was therefore supposed to be derived from the *condensation* of the oxygen gas in the new combination into which it entered.

Though *approaching* to the truth, this explanation is not strictly true. It is not merely from the oxygen gas being *condensed* that the caloric is evolved, because, in many cases of combustion, the product still exists in the gaseous state, and in others, the quantity of caloric evolved bears no proportion to the degree of condensation. Philosophers ascribed this to a change of capacity; for, in different bodies, the difference in the proportion of the capacities before and after combustion, is by no means uniform; and hence the difference in the quantities of caloric extricated in various cases of combustion.

This being premised, it remains to explain the origin of the light emitted during combustion; for although we take it for granted that the caloric is evolved from the oxygen gas, we cannot infer that the light has the same origin.

It is very probable that light is a constituent part of inflammable bodies; for it is frequently evolved in combinations when the oxygen is merely *transferred* from one inflammable substance to another. In those cases it must proceed from the inflammable body. The accension of oils by the affusion of acids, the combustion of metals in the same way, furnish instances of the kind.

It seems, therefore, probable that the light is derived from the inflammable substance; and that the oxygen, combining with the bases of these substances, disengages the light.

It may be concluded then, that light enters into the composition of all combustible bodies; but as we are unable to separate the light, so as to obtain these bodies pure, we treat of them as simple bodies.

According to this theory, the combustion of phosphorus in oxygen gas, is therefore, the effect of a double affinity. The basis of the oxygen gas unites with the phosphorus, to form phosphoric acid; and the light disengaged from the phosphorus, together with the heat of the oxygen gas, produces the vivid flame.

The quantity of light emitted by different bodies is supposed to depend on the quantity contained in them, and on the proportion in which it is united to caloric.

Such is the theory of combustion of Lavoisier, modified by Gren, Leonardi, and Richter.

Thomson's Theory of Combustion.

Though the preceding theory of combustion is simple and beautiful, it appears, from what we are now going to state, to be by no means completely satisfactory.

It has misled chemists, by confining the term combustion to the act of oxygenation, and considering that all bodies, during their combustion, combine with oxygen, without at the same time recollecting that this latter effect may take place without any of the phenomena usually attendant on combustion; and that, though certainly all combustion pre-supposes the combination of oxygen with a base, yet this combination may be, and repeatedly is, effected where no combustion can possibly take place. Nothing can be more evident than the difference which, in numberless instances, prevails between the act of oxygenation in bodies and that of combustion, inasmuch as neither the phenomena attending on, nor the results arising from them, are the same. That a distinction therefore should be made between these processes is obvious; and it is on this account that Dr. Thomson has offered a theory, which considers this subject in a new point of view, and which bids fair to enable us to estimate the phenomena of combustion much better than has hitherto been done.

According to Dr. Thomson's theory, all the bodies concerned in combustion are either, 1. *Combustibles.*—2. *Supporters of combustion.*—3. *Incombustibles.*

I. Combustible bodies are those substances which are said, in common language, to *burn*. During the combustion, they appear to emit light and heat, and, at the same time, gradually waste away. When this change has reached its *maximum*, the process of combustion is at an end.

The class of combustibles is very numerous; but all the bodies belonging to it may be sub-divided into three sets, namely: 1. Simple combustibles. 2. Compound combustibles. 3. Combustible oxides, &c.

Simple Combustibles.

1. Sulphur.
2. Phosphorus.
3. Diamond, or Carbon.
4. Hydrogen gas.
5. All the metals.
6. Boron.

Compound Combustibles.

The *compound combustibles* consist of compounds, formed by the simple combustibles uniting together, and are of course much more numerous than the simple combustibles. They may be arranged under the five following heads:

1. Sulphurets.
2. Phosphurets.
3. Carburets.
4. Alloys.
5. Sulphuretted, phosphuretted, and carburetted hydrogen.

The *combustible oxides* are either simple, having a single base, or compound, having more than one base. All the simple combustible oxides are by combustion converted into acids.

The compound combustible oxides are by far the most numerous.

II. The supporters of combustion are bodies which are not of themselves, strictly speaking, capable of undergoing combustion, but which are absolutely necessary for the process; for no combustible body can burn unless some one or other of them be present. Whenever they are excluded, combustion ceases. All the supporters of combustion known at present are oxygen, chlorine, iodine, and the compounds which these form with each other, and with azote.

There are indeed certain substances besides these, which possess nearly the same properties; these shall be afterwards enumerated under the title of *partial supporters.*

III. The INCOMBUSTIBLE BODIES are neither capable of undergoing combustion themselves, nor of supporting the combustion of those bodies that are; they are therefore not immediately connected with combustion; though most of them appear to be the results of that process. Azote, the alkalies, earths, &c. come under this division.

Some of the alkalies and earths possess certain properties in common with combustibles, and are capable of exhibiting phenomena somewhat analogous to combustion; which will be described afterwards under the title of *semi-combustion.*

In every case of combustion, there must therefore be present a *combustible* body, and a *supporter* of combustion. During combustion, the combustible always unites with the supporter. *It is this combination which occasions the apparent waste and alteration of the combustible.* The new compound thus formed is a *product of combustion.* Every product of combustion is either, 1. *an acid*, or 2. *an oxide*, &c. It is true, indeed, that other bodies sometimes make their appearance during combustion, but these will be found, upon examination, not to be products, nor to have undergone combustion.

Thus one of the two characteristic marks which distinguish combustion, namely, the apparent *waste and alteration of the combustible body*, has been fully explained. For the explanation of it we are indebted to Lavoisier, as stated before.

But though the combination of the combustible with oxygen, or other supporter, be a constant part of combustion, yet the facility with which combustibles burn is not proportional to their apparent affinity for oxygen.

Phosphorus, for instance, burns more readily than charcoal; yet charcoal is capable of abstracting oxygen from phosphorus, and of course has a greater affinity for it. Some of the combustible oxides take fire more readily than some of the simple combustibles; alkohol, ether, and oils, are exceedingly combustible, whereas all the metals require very high temperatures when the supporter is air.

This greater combustibility of combustible oxides is probably owing to the weaker affinity by which their particles are united. Hence they are more easily separated than homogeneous particles, and of course combine more readily with oxygen; those simple combustibles which melt easily, or which are in the state of elastic fluids, are also very combustible, because the cohesion between their particles is easily overcome.

It is owing to the same inferiority in the cohesion of heterogeneous particles, that some of the compound supporters occasion combustion in circumstances when the combustibles would not be acted on by simple supporters.

Thus phosphorus burns in air at the common temperature; but it does not burn in oxygen gas, unless its temperature be raised. Thus also oils burn rapidly when mixed with nitric acid. Nitrous gas and nitrous oxide constitute exceptions to this rule.

None of the *products* of combustion are combustible, according to the definition of combustion here given. This want of combustibility is not owing to their being saturated with oxygen; for several of them are capable of combining with an *additional dose* of it. But, during this combination, no caloric or light is ever emitted; and the compound formed differs essentially from a *product* of combustion; for by this additional dose of oxygen, the *product* is converted into a *supporter. Hence we see that combustion ought not to be confounded with the combination of a body with oxygen*, as was done formerly.

Combustion, indeed, cannot take place without the combination of oxygen or other supporter; but oxygen may combine with bodies in different proportions without the phenomena of combustion; and the *product obtained* by combustion is capable of becoming converted into a *supporter* of *combustion;* for instance, if lead be melted, and kept so for some time, it becomes covered with a grey pellicle or *oxide of lead*, a product consisting of oxygen and lead; but if this oxide is suffered to be heated longer, it absorbs an additional quantity of oxygen, and becomes converted into a yellow powder, called yellow *oxide of lead.* If this yellow oxide be again exposed to heat, it absorbs still more oxygen, and becomes converted into *red oxide of lead.* When the *supporters* thus formed by the combination of oxygen with *products*, are made to support combustion, they do not lose all their oxygen, but only the additional dose which constituted them supporters. Of course they are again reduced to their original state of products of combustion. Hence it follows, that they owe their properties as supporters, not to the *whole* of the oxygen which they contain, but to the *additional dose* which constituted them supporters. We may therefore call them *partial supporters*, indicating by the term, that part only of their oxygen is capable of supporting combustion, and not the whole.

All the partial supporters with which we are acquainted, contain a metallic basis; for metallic oxides are the only products at present known, capable of combining with an additional dose of oxygen. It is a circumstance highly deserving attention, that when metals are capable of combining with several doses of oxygen, the product, or oxide formed by combustion is seldom or never that which contains a *maximum* of oxygen.

Thus it is evident that several of the products of combustion are capable of combining with oxygen. *The incombustibility of products, therefore, is not owing to their want of affinity for oxygen,* but to some other cause.

No product of combustion is capable of *supporting* combustion. This is not occasioned by any want of affinity to combustible bodies; for several of them are capable of combining with an additional dose of their basis. But by this combination, they *lose* their properties as products, and are converted into *combustibles*. The process, therefore, differs essentially from combustion. Thus phosphoric acid, a product of combustion, is capable of combining with an additional dose of phosphorus, and forming *phosphorous* acid a combustible body. When this last acid is heated in contact with a supporter, it undergoes combustion; but it is only the additional dose of the combustible which burns, and the whole is converted into phosphoric acid. Hence we see that it is not the whole basis of these compounds which is combustible, but merely the additional dose. The compounds, therefore, formed by the union of a product and combustible, may be termed *partial combustibles;* indicating by the name, that a part only of the base is capable of undergoing combustion. Since the products of combustion are capable of combining with oxygen, but never exhibit the phenomena of combustion, except when they are in the state of partial combustibles, combustible bodies must contain a substance which they lose in burning, and to which they owe their combustibility; for, after they have lost it, they unite to oxygen *without* exhibiting the phenomena of combustion.

Though the products of combustion are not capable of supporting combustion, they not unfrequently part with their oxygen just as supporters do, give it out to combustibles, and convert them into products; but during this process, no heat nor light is ever evolved. Water, for instance, gives out its oxygen to iron, and converts it into the *black oxide,* a product. Thus we see that the oxygen of products is capable of converting combustibles into products, just as the oxygen of supporters; but during the combination of the last only, are heat and light emitted. The oxygen of supporters then contains something which the oxygen of products wants.

Whenever the whole of the oxygen is abstracted from products, the combustibility of their base is restored as completely as before combustion; but no substance is capable of abstracting the whole of the oxygen, except a *combustible,* or a *partial combustible.* Water, for instance, is a product of combustion, whose base is hydrogen. To restore the combustibility of the hydrogen, we have only to mix water with iron or zinc filings, and an acid; the metal is oxidized, and the hydrogen gas is evolved as combustible as ever. But no substance, except a combustible, is capable of separating hydrogen gas from water, by combining with its oxygen. Thus we see that combustibles are capable of restoring the combustibility of the bases of products; but they themselves lose their combustibility by the process, and are converted into products. Combustibility, therefore, may be thrown at pleasure from one body to another.

From these facts it is obvious that the products of combustion may be formed without combustion; but in these cases a new combustible is always evolved. The process is merely an interchange of combustibility; for the combustible is converted into a product only by means of a product. Both the oxygen and the base of the product having undergone combustion, have lost something which is essential to combustion. The process is merely a double decomposition. The product yields its oxygen to the combustible, while at the same time the combustible gives out something to the base of the product; the combustibility of that base then is restored by the loss of its oxygen, and by the restoration of something which it receives from the other combustible thus converted into a product.

There is indeed another method of forming the products of combustion without actual combustion in certain cases; but the phenomena are much more complicated. This method is to expose them to the action of some of the supporters dissolved in water; especially nitric acid. Thus most of the metallic oxides may be formed without combustion by the action of that acid on the metals. But, in that case, a new supporter is always evolved, namely, nitrous gas; ammonia, a new combustible, is also usually formed; and, not unfrequently, the *product* is converted into a *partial supporter.*

No *supporter* can be produced by combustion, or by any equivalent process. As several of the supporters consist of oxygen combined with a base, it follows as a consequence, that oxygen may combine with a base without losing that ingredient, which occasions combustion. The act of combination of oxygen with a base, therefore, is by no means the same with combustion. If we take a view of the different supporters, we shall find that all of them which can be obtained artificially, are procured either from other supporters or by the agency of electricity.

I. Oxygen gas may be procured from nitric acid, and from several of the partial supporters, as the black oxide of manganese, the red oxides of lead and of mercury. The action of heat is always necessary; but the process is very different from combustion.

II. Air, as far as is known at present,

cannot be formed artificially. The gas, indeed, which comes over during part of the usual distillation of nitrate of potash and sulphuric acid, to obtain nitric acid, resembles air very closely. But it is obtained from a supporter.

III. Nitrous oxide has hitherto been only procured from nitrous gas and nitric acid (in nitrate of ammonia,) both of which are supporters.

IV. Nitrous gas can only be procured by the decomposition of nitric acid, a supporter.

V. Oxymuriatic acid, or Chlorine, can be formed by the action of muriatic acid on the black oxyde of manganese, the red oxides of lead, iron, or mercury; all of which are partial supporters.

VI. Nitric acid is formed spontaneously upon the surface of the earth, by processes with which we are but imperfectly acquainted; but which certainly have no resemblance to combustion. Its oxygen is probably furnished by the *air*, which is a supporter; at least, it has been observed, that nitrogen and oxygen, at high temperatures, are capable of forming nitric acid.

This formation of nitric acid by means of electricity, has been considered as a combustion, but for what reason it is not easy to say: the substance acted upon is not a combustible with a supporter, but a supporter alone. Electricity is so far from being equivalent to combustion, that it sometimes acts in a manner diametrically opposite; *unburning*, if we may use the expression, a substance which has already undergone combustion, and converting a *product* into a *combustible* and a *supporter*. Thus it decomposes water, and converts it into oxygen and hydrogen gas; therefore it must be capable of supplying the substances which the oxygen and combustible lose when they combine by combustion, and form a product.

Several of the supporters and partial supporters are capable of combining with combustibles, without undergoing decomposition, or exhibiting the phenomena of combustion. In this manner, the yellow oxide of gold combines with ammonia; the red oxide of mercury with oxalic acid; and oxymuriatic acid with ammonia. Thus also nitrate of potash may be combined, or at least intimately mixed with several combustible bodies, as in gun-powder, fulminating powder, &c. In all these compounds, the oxygen of the supporter and the combustible retain the ingredients which render them susceptible of combustion; hence the compound is still combustible. And in consequence of the intimate combination of the component parts, the least alteration is apt to destroy the equilibrium which subsists between them; the consequence is, combustion and the formation of a new compound. Hence these compounds burn with amazing facility, not only when heated, but when triturated, or struck smartly with a hammer. They have therefore received the name of *detonating* or *fulminating* bodies. Thus we have fulminating gold, fulminating mercury, fulminating powder, &c.

Such are the properties of the combustibles, the supporters, and the products; and such the phenomena which they exhibit when made to act upon each other.

If we compare together the *supporters* and the *products*, we shall find that they resemble each other in many respects. Both of them contain oxygen, or other supporter, as an essential constituent part; both are capable of converting combustibles into products; and several of both combine with combustibles and with additional doses of oxygen. But they differ from each other in their effects on combustibles. The former only produce combustion; whereas the products convert combustibles into products without combustion. Now, as the ultimate change produced upon combustibles by both these sets of bodies is the same, and as the substance which combines with the combustibles is in both cases the same, oxygen for instance, we must conclude that this oxygen in the supporters contains something which the oxygen of the products wants, something which separates during the passage of the oxygen from the product to the combustible, and occasions the combustion, or emission of fire, which accompanies this passage. The oxygen of supporters then contains some ingredient which the oxygen of products wants. Many circumstances concur to render it probable that this ingredient is *caloric*.

The *combustibles* and the *products* also resemble each other. Both of them contain the same or a similar base; both frequently combine with combustibles, and likewise with oxygen; but they differ essentially in the phenomena which accompany their combination with oxygen. In the one case, *fire is emitted*; in the other, not. If we recollect that no substance but a combustible is capable of restoring combustibility to the base of a product, and that at its doing so it always loses its own combustibility; and if we recollect farther, that the base of a product does not exhibit the phenomena of combustion even when it combines with oxygen, we cannot avoid concluding, that all combustibles contain an ingredient which they lose when converted into products, and that this loss contributes to the fire which makes its appearance during the conversion. Many circumstances contribute to render it probable that this ingredient is *light*.

If we suppose that the oxygen of supporters contains caloric as an essential ingredient, and that light is a component part of all combustibles, the phenomena of combustion above enumerated, numerous and intricate as they are, admit of an easy and obvious explanation. The component parts of the oxygen of supporters are two; namely, 1. a base, 2. caloric. The component parts of combustibles are likewise two; namely, 1. a base, 2. light. During combustion, the base of the oxygen combines with the base of the combustible, and forms the product; while, at the same time, the caloric of the oxygen combines with the light of the combustible, and the compound flies off in the form of fire. Thus combustion is a double decomposition; the oxygen and combustible divide themselves each into two portions, which combine in pairs; the one compound is the *product*, and the other the *fire*, which escapes.

Hence the reason that the oxygen of products is unfit for combustion. It wants its caloric. Hence the reason that combustion does not take place when oxygen combines with products, or with the base of supporters. These bodies contain no light. The caloric of the oxygen of course is not separated, and no fire appears. And this oxygen still retaining its caloric, is capable of producing combustion whenever a body is presented which contains light, and whose base has an affinity for oxygen. Hence also the reason why a combustible alone can restore combustibility to the base of a product. In all such cases, a double decomposition takes place. The oxygen of the product combines with the base of the combustible, while the light of the combustible combines with the base of the product.

But the application of this theory to all the different phenomena described above, is so obvious, that it is needless to give any more examples. Let us rather inquire, with the author, into the evidences which can be brought forward in its support.

As caloric and light are always emitted during combustion, it follows that they must have previously existed in the combustible, the supporter, or in both.

That the oxygen of the supporters contains either one or both of these substances, follows incontrovertibly from a fact already mentioned, namely, that the oxygen of products will not support combustion, while that of supporters will. Hence the oxygen of supporters must contain something which the oxygen of the products wants, and this something must be caloric, or light, or both.

That the oxygen of some of the supporters at least contains caloric, as an ingredient, has been proved, in a satisfactory manner, by the experiments of Crawford, Lavoisier, and La Place. Thus the temperature of hot-blooded animals is maintained by the decomposition of *air*. Now if the oxygen of one supporter contains caloric, the same ingredient must exist in the oxygen of every supporter, because all of them are obviously in the same state. Hence we conclude that the oxygen of every supporter contains caloric as an essential ingredient.

The light emitted during combustion must either proceed from the combustible or the supporter. That it proceeds from the combustible, must appear pretty obvious, if we recollect that the colour of the light emitted during combustion varies, and that this variation usually depends, not upon the supporter, but upon the combustible. Thus charcoal burns with a red flame, sulphur with a blue or violet, zinc with a greenish-white, &c.

The formation of combustibles in plants, obviously requires the presence and agency of light. The leaves of plants emit oxygen gas, when exposed to the sun's rays, but never in the shade, or in the dark.

Besides vegetation, we are acquainted with two other methods of *unburning* products, or of converting them into products and combustibles, by exposing them, in certain circumstances, to the agency of *fire*, or of *electricity*. The oxides of gold, mercury, &c. when heated to redness, are decomposed, oxygen gas is emitted, and the pure metal remains behind. In this case, the necessary caloric and light must be furnished by the fire; a circumstance which explains why such reductions always require a red heat. When carbonic acid is made to pass repeatedly over red-hot charcoal, it combines with a portion of charcoal, and is converted into gaseous oxide of carbon. If this gas be a combustible oxide, the base of the carbonic acid and its oxygen must have been supplied with light and caloric from the fire; but if it be a *partial combustible*, it is merely a compound of carbonic acid and charcoal: which of the two it is, remains still to be ascertained.

Electricity decomposes water, and converts it into oxygen gas and hydrogen gas; it must, therefore, supply the heat and the light which these bodies lost when converted into a product.

These facts, together with the exact correspondence of the theory given above with the phenomena of combustion, render it so probable, that Dr. Thomson has ventured to propose it as an additional step towards a full explanation of the theory of combustion. Every additional experiment has served to confirm it more and more. It even throws light upon the curious experiments of the accension of metals with sulphur, which succeed *in vacuo*, under mercury, in nitrogen gas, &c.

Dr. Thomson has noticed, that the same emission of caloric and light, or of *fire*, takes place when melted sulphur is made to combine with potash, or with lime, in a crucible or glass tube, and likewise when melted phosphorus is made to combine with lime heated to redness. He supposes that, in all probability, barytes and strontia exhibit the same phenomenon when combined with melted sulphur or phosphorus; and perhaps some of the metals when combined with phosphorus.

The phenomena Dr. Thompson explains thus: — The sulphur and phosphorus are in the melted state, and therefore contain caloric as an ingredient; the alkalies, earths, and metals which produce the phenomenon in question, contain light as an essential ingredient. The sulphur, or phosphorus combines with the base of the metal, earth, or alkali; while, at the same time, the *caloric,* to which the sulphur or phosphorus owed its fluidity, combines with the *light* of the metal, earth, or alkali; and the compound flies off under the form of *fire.*

Thus the process is exactly the same with combustion, excepting as far as regards the product. The melted sulphur, or phosphorus, acts the part of the *supporter,* while the metal, earth, or alkali, occupies the place of the *combustible.* The first furnishes caloric, the second light, while the base of each combines together. Hence we see that the base of sulphurets and phosphurets resembles the base of products in being destitute of light; the formation of these bodies exhibiting the separation of fire like *combustion,* but the product differing from a product of combustion in being destitute of oxygen, Dr. Thomson distinguishes the process by the title of *semi-combustion;* indicating by the term, that it possesses one half of the characteristic marks of combustion, but is destitute of the other half.

The only part of this theory which requires proof is, that light is a component part of the earths and alkalies. But as potash and lime are the only bodies of that nature, which we are certain to be capable of exhibiting the phenomena of semi-combustion, the proofs must of necessity be confined to them. That *lime* contains light as a component part, has been long known. Meyer and Pelletier observed long ago, that when water is poured upon lime, not only heat but light is emitted. Light is emitted also abundantly, when sulphuric acid is poured upon magnesia, or upon lime, potash, or soda, freed from the water of crystallization. In all these cases, a *semi-combustion* takes place. The water and the acid being solidified, give out *caloric,* while the lime or potash gives out *light.*

That lime, during its burning, combines with light, and that light is a component part of lime, is demonstrated by the following experiment, for which we are indebted to Scheele.

Fluor spar (fluate of lime) has the property of phosphorescing strongly when heated, but the experiment does not succeed twice with the same specimen. After it has been once heated sufficiently, no subsequent heat will cause it to phosphoresce. Now phosphorescence is merely the emission of light; light of course is a component part of fluor spar, and heat has the property of separating it. But the phosphorescing quality of the spar may be again recovered to it, or, which is the same thing, the light which the spar had lost may be restored by the following process: —

Decompose the fluate of lime by sulphuric acid, and preserve the fluoric acid separate. Boil the sulphate of lime thus formed, with a sufficient quantity of carbonate of soda; a double decomposition takes place; sulphate of soda remains in solution, and carbonate of lime precipitates. Ignite this precipitate in a crucible, till it is reduced to lime, and combine it with the fluoric acid to which it was formerly united. The fluor spar thus regenerated, phosphoresces as at first. Hence the lime, during its ignition, must have combined with light.

That potash contains light, may be proved in the same manner as the existence of that body in lime. Now as potash is deprived of its carbonic acid by lime, the Doctor supposes that the process must be a double decomposition; namely, that the base of the lime combines with carbonic acid, while its light combines with the potash.

These remarks on semi-combustion might easily be much enlarged upon: for it is obvious, that whenever a liquid combines with a solid containing light, and the product is a solid body, something analogous to semi-combustion must take place.

Comedo'nes. (From *comedo,* a glutton.) A sort of worms which eat into the skin and devour the flesh.

Co'mfrey. See *Symphytum.*

Comi'sdi. The gum-arabic.

Comi'ste. The epilepsy. This name arose from the frequency of persons being seized with this disorder, while in the assemblies called Comitia.

Comiti'ssa. (A countess.) Some preparations are distinguished by this name, as pulvis Comitissæ de Cantia, the Countess of Kent's powder. Also the Cinchona was called *Pulvis Comitissæ.*

Commage'num. (From *Commagene,* a place in Syria, whence it was brought.) Syrian ointment, mentioned by Galen.

Commanduca'tio. (From *commanduco,* to eat.) The act of mastication, or chewing.

Comma'nsum. (From *commando,* to eat.) A masticatory. A medicine put into the mouth and chewed, to promote a discharge of phlegm, or saliva.

Commendato'rius. (From *commendo,* to recommend.) An epithet of the traumatic balsam, Tinctura Benzoes composita, from its singular virtues and usefulness.

Co'mmi. Gum. When alone it signifies gum arabic. The κομμι λευκον mentioned by Hippocrates in his De Morb. Mulieb. is gum arabic.

COMMISSU'RA. (From *committo,* to join together.) A suture, juncture, or joint. A term applied in anatomy to the corners of the lips, where they meet together; and also to certain parts of the brain which go across and join one hemisphere to the other.

COMMISSU'RA ANTE'RIOR CE'REBRI. The white nerve-like substance which crosses the anterior part of the third ventricle of the brain, immediately above the infundibulum, and between the anterior crura of the fornix; uniting one hemisphere of the brain with the other.

COMMISSU'RA MA'GNA CE'REBRI. The *corpus callosum* of the brain is so termed by some writers.

COMMISSU'RA POSTE'RIOR CE'REBRI. A white nerve-like substance, which passes from one hemisphere of the brain across to the other, immediately over the opening of the aquæduct of Sylvius, in the posterior part of the third ventricle of the brain, and above the *corpora quadrigemina*.

Commu'nicant. (From *communico*, to make partake.) A term applied, by Bellini, to fevers of two kinds afflicting the same person, wherein as one goes off the other immediately succeeds

Compa'ges. (From *compingo*, to put together.) A suture, or joint. A commissure.

COMPA'RATIVE ANA'TOMY. *Anatomia comparativa.* Zootomy. The dissection of brute animals and fishes, to compare them with the human body.

Compe'ba. See *Piper Cubeba.*

Comple'tion. A term used by the antient writers in various acceptations; but latterly it signifies only the same as *Plethora.*

COMPLE'XUS. (*Complexus*, sc. *musc.* from *complector*, to comprise.) *Complexus seu biventer cervicis* of Albinus. *Dorso trachelon occipital* of Dumas. A muscle situated on the back part of the neck, that draws the head backwards, and to one side; and when both act, they draw the head directly backward. It arises from the transverse processes of the seven superior vertebræ of the back, and four inferior of the neck, by as many distinct tendinous origins; in its ascent, it receives a fleshy slip from the spinous process of the first vertebra of the back: from these different origins it runs upwards, and is every where intermixed with tendinous fibres. It is inserted, tendinous and fleshy, into the inferior edge of the protuberance in the middle of the os occipitis, and into a part of the curved line that runs forwards from that protuberance. It draws the head backwards.

Comple'xus mi'nor. See *Trachelo-mastoideus.*

COMPRE'SSION. (From *comprimo*, to press together.) By this term, surgeons express a diseased state of the body, which is the effect of something pressing upon the brain. It should be distinguished from concussion and inflammation. When the brain is compressed either by bone, extravasated blood, or any other fluid, there is a general insensibility, the eyes are half open, the pupils dilated and motionless, even when a candle is brought near the eye; the retina is insensible; the limbs relaxed; the breathing stertorous; the pulse slow, and, according to Mr. Abernethy, less subject to intermission than in cases of concussion. Nor is the patient ever sick, when the pressure on the brain, and the general insensibility, are considerable; for the very action of vomiting betrays an irritability in the stomach and œsophagus.

COMPRE'SSOR NA'RIS. (*Compressor;* from *comprimo*, to press together.) *Rinæus vel nasalis* of Douglas. *Transversalis vel myrtiformis* of Winslow. *Dilatores alarum nasi* of Cowper; and *Maxillo narinal* of Dumas. A muscle of the nose, that compresses the alæ towards the septum nasi particularly when we want to smell acutely, It also corrugates the nose, and assists in expressing certain passions. It arises, by a narrow beginning, from the root of the ala nasi externally, and spreads into a number of thin, separate fibres, which run up along the cartilage in an oblique manner towards the back of the nose, where it joins with its fellow, and is inserted into the narrow extremity of the os nasi, and nasal process of the superior maxillary bone.

Compu'nctio. (From *compungo*, to prick.) A puncture.

CONA'RIUM. (From *κωνος*, a cone.) The pineal gland is so named, from its conical shape. See *Pineal gland.*

Concau'sa. (From *con*, with, and *causa*, a cause.) A cause which co-operates with another in the production of a disease.

Concentra'ntia. (From *concentro*, to concentrate.) Absorbents of acids are so called, because they remove the obstructions which keep asunder the affinities between the two powers.

CONCENTRA'TION. (From *con*, and *centrum*, a centre.) The volatilizing of part of the water of fluids, in order to improve their strength. The matter to be concentrated, therefore, must be of superior fixity to water. This operation is performed on some acids, particularly the sulphuric and phosphoric. It is also employed in solutions of alkalies and neutral salts.

CONCE'PTION. (*Conceptio;* from *concipio*, to conceive.) The impregnation of the ovulum in the female ovarium, by the subtile prolific aura of the semen virile. In order to have a fruitful coition, it is necessary that the semen be propelled into the uterus, or vagina, so that its fecundating vapour shall be conveyed through the Fallopian tube to the ovarium: it is also necessary that there be a certain state of the ovarium of the female in order to impregnate it; which is, that the ovum shall be mature, and embraced by the fimbriæ of the Fallopian tube, to convey that vivifying principle to the ovum. See *Generation.*

CO'NCHA. (*Concha*, *κογχη*, a liquid measure amongst the Athenians.) A term applied by anatomists to several parts of the body, as the hollow of the ear, the spongy bones of the nose, &c.

Co′ncha auri′culæ. See *Auricula.*

Co′ncha au′ris. The hollow part of the cartilage of the outer ear.

Co′nchæ na′rium. (*Concha*, a shell.) The turbinated portion of the ethmoid bone, and the inferior spongy bones of the nose, which are covered by the Schneiderian membrane, are so termed.

Co′nchus. (From κογχη, a shell; so named from their likeness to a shell.) The cranium, and the cavity of the eye.

Concide′ntia. (From *concido*, to decay.) A decrease of bulk in the whole or any part of the body. A diminution of a tumour.

Concoagula′tio. (From *con*, and *coagulo*, to coagulate together.) The coagulation or crystallization of different salts, first dissolved together in the same fluid.

Conco′ctio. (From *concoquo*, to digest.) Digestion. That operation of nature upon morbid matter which renders it fit to be separated from the healthy fluids.

Concrema′tio. (From *con*, and *cremo*, to burn together.) The same as calcination.

CONCRE′TION. (From *concresco*, to grow together.)

1. The condensation of any fluid substance into a more solid consistence.

2. The growing together of parts which, in a natural state, are separate.

Concu′rsus. (From *concurro*, to meet together.) The congeries or collection of symptoms which constitute and distinguish the particular disease.

CONCU′SSION. (From *concutio*, to shake together.) Concussion of the brain. Various alarming symptoms, followed sometimes by the most fatal consequences, are found to attend great violence offered to the head; and upon the strictest examination, both of the living and the dead, neither fissure, fracture, nor extravasation of any kind can be discovered. The same symptoms and the same events are met with, when the head has received no injury at all *ab externo*, but has only been violently shaken; nay, when only the body, or general frame, has seemed to have sustained the violence. The symptoms attending a concussion, are generally in proportion to the degree of violence which the brain itself has sustained, and which, indeed, is cognizable only by the symptoms. If the concussion be very great, all sense and power of motion are immediately abolished, and death follows soon; but between this degree and that slight confusion (or stunning, as it is called,) which attends most violences done to the head, there are many shades. The following is Mr. Abernethy's description of the symptoms of concussion, and which, he is of opinion, may be properly divided into three stages.

The first is, that state of insensibility and derangement of the bodily powers which immediately succeeds the accident. While it lasts, the patient scarcely feels any injury that may be inflicted on him. His breathing is difficult, but in general without stertor; his pulse intermitting, and his extremities cold. But such a state cannot last long; it goes off gradually, and is succeeded by another, which is considered as the *second* stage of concussion. In this, the pulse and respiration become better, and, though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The feeling of the patient is now so far restored, that he is sensible of his skin being pinched; but he lies stupid and inattentive to slight external impressions. As the effects of concussion diminish, he becomes capable of replying to questions put to him in a loud tone of voice, especially when they refer to his chief suffering at the time, as pain in the head, &c.; otherwise he answers incoherently, and as if his attention was occupied by something else. As long as the stupor remains, the inflammation of the brain seems to be moderate; but as the former abates, the latter seldom fails to increase; and this constitutes the *third* stage, which is the most important of the series of effects proceeding from a concussion.

These several stages vary considerably in their degree and duration; but more or less of each will be found to take place in every instance where the brain has been violently shaken. Whether they bear any certain proportion to each other or not, is not known; indeed this will depend upon such a variety of circumstances in the constitution, the injury, and the after-treatment, that it must be difficult to determine.

To distinguish between an extravasation and a concussion by the symptoms only, Mr. Pott says, is frequently a very difficult matter; sometimes an impossible one. The similarity of the effects in some cases, and the very small space of time which may intervene between the going off of the one and accession of the other, render this a very nice exercise of the judgment. The first stunning or deprivation of sense, whether total or partial, may be from either, and no man can tell from which; but when these first symptoms have been removed, or have spontaneously disappeared, if such patient is again oppressed with drowsiness, or stupidity, or total or partial loss of sense, it then becomes probable that the first complaints were from concussion, and that the latter are from extravasation; and the greater the distance of time between the two, the greater is the probability not only that an extravasation is the cause, but that the extravasation is of the limpid kind, made gradatim, and within the brain.

Whoever seriously reflects on the nature of these two causes of evil within the cranium, and considers them as liable to frequent combination in the same subject, and at the same time considers that, in many instances, no degree of information can be obtained from the only person capable of giving it (the patient), will immediately be sensible how very difficult a part a practitioner has to act in many of these cases, and how very unjust it must be to call that ignorance which is only a just diffidence arising from the obscurity of the subject, and the impossibility of attaining materials to form a clear judgment.

Mr. Abernethy observes, that in cases of simple concussion, the insensibility is not so great, as where compression exists, the pupils are more contracted, the muscles less relaxed, little or no stertor attends, but the pulse is generally very intermitting, and in slight cases there is often considerable sickness.

Very different modes of treating these accidents have been practised, and no doubt the same means should not be pursued indiscriminately. Much must depend on the state of the patient, when he received the injury, the degree of this, the time which has elapsed since, and other circumstances. Mr. Abernethy considers, that in the first stage little should be done; that the stimulants often employed may be even injurious; but more especially so in the second stage, increasing the tendency to inflammation; and where this has come on, that the antiphlogistic plan must be actively pursued. However, a moderate abstraction of blood, general or topical, will be commonly proper at first, where the habit will allow it, as congestion may be suspected, and to obviate inflammation, especially where the person was intoxicated at the time of the accident; and the effect of this measure may influence the subsequent treatment. If the pulse rose after it, and the patient became more sensible, we should be led to pursue the evacuating plan, taking perhaps more blood, exhibiting active cathartics, as the bowels will be found very torpid, applying cold lotions to the head, &c. These means, however, will be especially called for, when marks of inflammation appear. Sometimes brisk emetics have been very beneficial, as sulphate of zinc, &c.: they are particularly recommended, where the person was under the influence of anger; or the stomach full, when the accident happened; but they are liable to objection, where there are marks of congestion, or increased action in the vessels of the head. If bleeding should lower the pulse, and render the patient worse, evacuations must not be pursued; it may be better generally to wait the gradual return of sensibility, unless the torpor be alarming, like a state of syncope: in which case, or if it continue very long, stimulants appear justified, as ammonia, or others of transient operation, with a blister to the head, to restore some degree of sensibility. If in the sequel marks of irritation appear, as spasms or convulsions, opium joined with antimony, or in the form of Dover's powder, will probably be useful, the necessary evacuations being premised, and the warm bath. In all cases the head should be kept quiet; as the patient is convalescent, tonics and the shower-bath may be employed with advantage; and it will be particularly necessary to avoid great bodily exertion, stimulating liquors, &c. Should paralytic symptoms remain, stimulants general or local may be required. Where alarming symptoms follow an injury to the head, extravasation may be suspected: and the operation of trepanning, skilfully performed, will do no harm to the patient, but may materially relieve, even by the loss of blood attending.

CONDENSA'TION. (From *condenso*, to make thick.) A contraction of the pores of the skin, by means of astringent or cooling medicines. A thickening of any fluid.

CONDIME'NTUM. (From *condio*, to preserve, or season.) A preserve, or sweetmeat.

Condu'ctio. (From *conduco*, to draw along.) In Cœlius Aurelianus, it is a spasm, or convulsion, drawing the muscles out of their proper positions.

CONDU'CTOR. (From *conduco*, to lead, or guide.) A surgical instrument, whose use is to direct the knife in certain operations. It is more commonly called a director.

CO'NDYLE. (From *κονδυ*, an antient cup, shaped like a joint.) A rounded eminence of a bone in any of the joints.

CONDYLO'MA. (From *κονδυλος*, a tubercle, or knot.) *Sarcoma.* A soft, wart-like excrescence, that appears about the anus and pudendum of both sexes. There are several species of condylomata, which have received names from their appearances, as *ficus*, *crystæ*, *thymus*, from their resemblance to a fig, &c.

Conei'on. In Hippocrates it imports hemlock. It is said to be thus named (from *κωναν*, to turn round,) because it produces a vertigo in those who take it inwardly. See *Conium*.

Conessi bark. See *Conessi cortex.*

Cone'ssi co'rtex. See *Nerium antidysentericum.*

CONFE'CTIO. (From *conficio*, to make up.) A confection. In general it means any thing made up with sugar. This term, in the new London Pharmacopœia, includes those articles which were formerly called electuaries and conserves, between which there do not appear to be sufficient grounds to make a distinction.

Confe'ctio amygdala'rum. Confection of almonds. Take of sweet almonds, an ounce; Acacia gum powdered, a drachm; refined sugar, half an ounce. The almonds having been previously macerated in water, and their external coat removed, beat the whole together, until they are thoroughly incorporated. It has been objected to the almond mixture, which is an article of very general use, that it requires considerable time for its extemporaneous preparation, and that it spoils and cannot be kept when it is made. This will be obviated by the present form, which does keep for a sufficient length of time, and rubs down into the mixture immediately.

Confe′ctio aroma′tica. This preparation was formerly called *Confectio cardiaca. Confectio Raleighana.* Take of cinnamon bark, nutmegs, of each two ounces; cloves, an ounce; cardamom seeds, half an ounce; saffron dried, two ounces; prepared shells, 16 ounces; refined sugar powdered, two pounds; water, a pint. Reduce the dry substances, mixed together, to very fine powder; then add the water gradually, and mix the whole, until it is incorporated. This preparation is now much simplified by the London college. It is an excellent medicine, possessing stimulant, antispasmodic, and adstringent virtues; and is exhibited with these views to children and adults, in a vast variety of diseases, mixed with other medicines. It may be given in doses of 10 gr. to a drachm.

Confe′ctio aurantio′rum. *Conserva corticis exterioris aurantii hispalensis. Conserva flavedinis corticum aurantiorum.* Take of fresh external rind of oranges, separated by rasping, a pound; refined sugar, three pounds. Bruise the rind with a wooden pestle, in a stone mortar; then, after adding the sugar, bruise it again, until the whole is thoroughly incorporated. This is well calculated to form the basis of a tonic and stomachic confection, and may be given alone in doses of from two to five drachms, twice or three times a-day.

Confe′ctio cardi′aca. See *Confectio aromatica.*

Confe′ctio ca′ssiæ. *Electuarium cassiæ. Electuarium e cassia.* Confection of cassia. Take of fresh cassia pulp, half a pound; manna, two ounces; tamarind pulp, an ounce; syrup of roses, half a pint. Bruise the manna; melt it in the syrup by a water-bath; then mix in the pulps, and evaporate down to a proper consistence. This is a very elegant, pleasant, and mild aperient for the feeble, and for children. Dose from two drachms to an ounce.

Confe′ctio o′pii. *Confectio opiata. Philonium Londinense. Philonium Romanum.* Confection of opium. Take of hard opium powdered, six drachms; long pepper, an ounce; ginger root, two ounces; caraway-seeds, three ounces; syrup, a pint. Rub together the opium and the syrup previously heated; then add the remaining articles reduced to powder, and mix. To the credit of modern pharmacy, this is the only one that remains of all those complicated and confused preparations called mithridate, theriaca, &c.; it more nearly approximates, in its composition, the philonium than any other, and may be considered as an effectual substitute for them in practice. This very warm and stimulating confection is admirably calculated to relieve diarrhœa, or spasms of the stomach and bowels, and is frequently ordered in doses of from 10 grs. to half a drachm. About 36 grains contain one of opium.

Confe′ctio ro′sæ cani′næ. *Conserva cynosbati. Conserva fructus cynosbati.* Conserve of hips. Confection of dog-rose. Take of dog-rose pulp, a pound; refined sugar powdered, twenty ounces. Expose the pulp in a water-bath to a gentle heat; then add the sugar gradually, and rub them together until they are thoroughly incorporated. This preparation is cooling and adstringent; it is seldom given alone, but mostly joined to some other medicine, in the form of linctus, or electuary.

Confe′ctio ro′sæ ga′llicæ. *Conserva rosæ. Conserva rosarum rubrarum.* Conserve of red rose. Take of the petals of the red rose, before it is expanded, and without the claws, a pound; refined sugar, three pounds. Bruise the petals in a stone mortar; then, having added the sugar, beat them again together, until they are thoroughly incorporated. This is an excellent subastringent composition. Rubbed down with water, it forms an excellent drink, with some lemon-juice, in hæmorrhagic complaints; it may also be given with vitriolated zinc, in the form of an electuary.

Confe′ctio ru′tæ. *Electuarium e baccis lauri.* Confection of rue. Take of rue leaves dried, caraway seeds, bay-berries, of each an ounce and a half; sagapenum, half an ounce; black pepper, two drachms; clarified honey, sixteen ounces. Rub the dry articles together, into a very fine powder; then add the honey, and mix the whole. Its use is confined to clysters.

Confe′ctio scammo′neæ. *Electuarium scammonii. Electuarium e scammonio. Electuarium caryocostinum.* Confection of scammony. Take of scammony gum resin powdered, an ounce and a half; cloves bruised, ginger root powdered, of each, six drachms; oil of caraway, half a drachm; syrup of roses, as much as is sufficient. Rub the dry articles together, into very fine powder; next rub them again whilst the syrup is gradually added; then add the oil of caraway, and mix the whole well together. This is a strong stimulating cathartic, and calculated to remove worms from the primæ viæ, with which view it is mostly exhibited. Dose from ʒss to ʒj.

Confe′ctio se′nnæ. *Electuarium sennæ. Electuarium lenitivum.* Confection of senna. Take of senna leaves, eight ounces; figs, a pound; tamarind pulp, pulp of prunes, cassia pulp, of each half a pound; coriander seeds, four ounces; liquorice root, three ounces; refined sugar, two pounds and a half. Powder the senna leaves with the coriander seeds, and separate, by sifting ten ounces of the mixed powder. Boil the remainder with the figs and the liquorice-root, in four pints of water, until it be reduced to half; then press out and strain the liquor. Evaporate the liquor, until a pint and a half only remains of the whole; then add the sugar, to make syrup. Lastly, mix the pulps gradually with the syrup, and, having added the sifted powder, mix the whole together. This is a mild and elegant aperient, well adapted for pregnant women, and those whose bowels are easily moved. Dose, ʒss to ℥ss.

CONFE′RVA. (From *conferveo,* to knit together.) 1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia.* Order, *Algæ.*

2. A kind of moss: named from its use formerly in healing broken bones.

Confe′rva helminthoco′rtos. See *Corallina corsicana.*

Confe′rva riva′lis. This plant, *Conferva; filamentis simplicissimus æqualibus longissimus,* of Linnæus, has been recommended in cases of spasmodic asthma, phthisis, &c. on account of the great quantity of vital air it contains.

Confirma′ntia. (From *con,* and *firmo,* to strengthen.) Restoratives; also medicines which fasten the teeth in their sockets.

Confluent small-pox. See *Variola.*

Conflu′xion. It is much used by Hippocrates, and his interpreter Galen, from a notion that parts at a distance have mutual consent with one another, and that they are all perspirable by many subtle streams. Paracelsus, according to his way, expressed the former by confederation.

CONFORMA′TIO. (From *conformo,* to shape or fashion.) The natural shape and form of any thing, also a description of some diseases which arise from a bad formation of parts.

Conforta′ntia. (From *conforto,* to strengthen.) Cordial medicines. Strengtheners.

Confortati′va. The same.

Confu′sio. (From *confundo,* to mix together.) A confusion, or disorder in the eyes, proceeding from a rupture of the membranes, which include the humours, by which means they are all confounded together.

Congela′ti. (From *congelo,* to freeze.) *Congelatici.* Persons afflicted with a catalepsy are so called, by which all sensation seems to be taken away.

Congela′tion. (From *congelo,* to freeze.) That change of liquid bodies which takes place when they pass to a solid state, by losing the caloric which kept them in a state of fluidity.

Congelati′va. (From *congelo,* to congeal.) Medicines that inspissate humours, and stop fluxions and rheums.

Co′ngener. (From *con,* and *genus,* kind.) Of the same kind; concurring in the same action. It is usually said of the muscles.

CONGE′STION. (From *congero,* to amass.) A collection of blood or other fluid; a swelling which rises gradually, and ripens slowly, in opposition to that which is soon formed, and soon terminated.

CONGLOBA′TE GLA′ND. (From *conglobo,* to gather into a ball.) *Glandula conglobata.* Lymphatic gland. Globate gland. A round gland formed of a contortion of lymphatic vessels, connected together by cellular structure, having neither a cavity nor any excretory duct: such are the mesenteric, inguinal, axillary glands, &c. See *Gland.*

CONGLOMERATE GLAND. (From *conglomero,* to heap upon one.) *Glandula conglomerata.* A gland composed of a number of glomerate glands, whose excretory ducts all unite into one common duct: such are the salival, parotid glands, &c.

CONGLUTINA′NTIA. (From *conglutino,* to glue together.) Healing medicines; and such as unite parts disjoined by accident.

Co′nis. (Κονις.) Dust, fine powder, ashes, a nit in the hair, scurf from the head; and sometimes it signifies lime.

CONI′UM. (From *κονια,* dust, according to Linnæus, or from *κωναω, circumago;* on account of its inebriating and poisonous quality.) Hemlock.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.*

2. The pharmacopœial name of the officinal hemlock. See *Conium maculatum.*

Coni′um macula′tum. The systematic name for the *cicuta* of the pharmacopœias. *Conium; seminibus striatis,* of Linnæus. It is called by some *camaran;* by others *abiotos;* and, according to Erotian, *cambeion* is an old Sicilian word for cicuta. *Cicuta major fœtida. Conium* of the last London pharmacopœia.

Hemlock is found in every part of England, and is distinguished from those plants which bear some resemblance to it, by the spotted stem. It is generally believed to be a very active poison. In a very moderate dose it is apt to occasion sickness and vertigo; in a larger quantity it produses anxiety, cardialgia, vomiting, convulsions, coma, and death. Baron Stoerk was the first who rought hemlock into repute as a medicine of extraordinary efficacy: and although we have not in this country any direct facts, like those mentioned by Stoerk, proving that inveterate scirrhuses, cancers, ulcers, and many other diseases hitherto deemed irremediable, are to be completely cured by the cicuta; we have however the testimonies of several eminent physicians, shewing that some complaints which had resisted other powerful remedies, yielded to hemlock; and that even some disorders, which if not really cancerous, were at least suspected to be of that tendency, were greatly benefited by this remedy. In chronic rheumatisms, some glandular swellings, and in various fixed and periodical pains, the cicuta is now very generally employed; and from daily experience, it appears in such cases to be a very efficacious remedy. It has also been of singular use in the hooping-cough. Nor is it less efficacious when applied externally; a poultice made of oatmeal and the expressed juice, (or a decoction of the extract, when the other cannot be obtained,) allays the most excruciating torturing pains of a cancer, and thus gives rest to the distracted patient.

The proper method of administering conium internally, is to begin with a few grains of the powder or inspissated juice, and gradually to increase the dose until a giddiness affects the head, a motion is felt in the eyes as if pressed outwards, with a slight sickness and trembling agitation of the body. One or more of these symptoms are the evidence of a full dose, which should be continued until they have ceased, and then after a few days the dose may be increased; for little advantage can be expected but by a continuance of the greatest quantity the patient can bear. In some constitutions even small doses greatly offend, occasioning spasms, heat and thirst; in such instances it will be of no service. As the powder of the dried leaves has been thought to act, and may be depended upon with more certainty than the extract, the following direction should be observed in the preparation: — Gather the plant about the end of June, when it is in flower; pick off the little leaves, and throw away the leaf-stalks: dry the small selected leaves in a hot sun, or in a tin or pewter dish before the fire. Preserve them in bags made of strong brown paper, or powder them and keep the powder in glass phials where the light is excluded; for light dissipates the beautiful green colour very soon, and thus the medicine loses its appearance, if not its efficacy: this mode is recommended by Dr. Withering. The extract should also be made of the plant gathered at this period. From 2 to 20 grains of the powder may be taken twice or thrice a day.

CONJUNCTIVE MEMBRANE. *Membrana conjunctiva.* The thin, transparent, delicate membrane, that lines the internal superficies of one eyelid, and is reflected from thence, over the anterior part of the bulb, then reflected again to the edge of the other eyelid. That portion which covers the transparent cornea cannot, without much difficulty, be separated from it. Inflammation of this membrane is called *ophthalmia.*

CONNA'TUS. (From *con*, and *nascor*, to grow together.) Used much by Hippocrates for what is born with a person; the same with *congenitus.*

CONNEXION. See *Articulation.*

CONNUTRI'TUS. (From *con*, and *nutrior*, to be nourished with.) It is what becomes habitual to a person from his particular nourishment, or what breaks out into a disease in process of time, which gradually had its foundation in the first aliments, as from sucking a distempered nurse, or the like.

CONQUASSA'TIO. Conquassation. In pharmacy it is a species of comminution, or an operation by which moist concrete substances, as recent vegetables, fruits, the softer parts of animals, &c. are agitated and bruised, till, partly by their proper succulence, or by the affusion of some liquor, they are reduced to a soft pulp.

CONRI'NGIUS, HERMAN, was born at Norden, in East Friesland, 1606, and graduated in medicine at Helmstat, where he soon after became professor in that science, and subsequently in physics, law, and politics. He was also made physician and aulic counsellor to the Queen of Sweden, the King of Denmark, and several of the German princes. He wrote numerous works in philosophy, medicine, and history, displaying great learning, and long highly esteemed. In one treatise he refers the degeneracy of the modern Germans to their altered mode of living, the use of stoves, tobacco, &c. He published also an "Introduction to the whole Art of Medicine, and its several Parts," containing a History and Bibliotheca Medica, with numerous Dissertations on particular Diseases. He died in 1681.

Consent of parts. See *Sympathy.*

CONSE'RVA. (From *conservo*, to keep.) A conserve. A composition of some recent vegetable and sugar, beat together into an uniform mass of the consistence of honey; as conserve of hips, orange peel, &c. Conserves are called confections in the last edition of the London Pharmacopœia. See *Confectio.*

CONSE'RVA ABSI'NTHII MARI'TIMI. See *Artemisia maritima.*

CONSE'RVA A'RI. This is occasionally exhibited as a stimulant and diuretic. See *Arum.*

CONSE'RVA AURA'NTII HISPALE'NSIS. See *Confectio aurantiorum.*

CONSE'RVA CYNO'SBATI. See *Confectio rosæ caninæ.*

CONSE'RVA LU'JULÆ. A preparation of wood-sorrel, possessing acid, cooling, and antiseptic qualities. See *Oxalis acetosella.*

Conse′rva men′thæ. This preparation of mint is given occasionally as a stomachic, in sickness and weakness of the stomach. See *Mentha viridis*.

Conse′rva pru′ni sylve′stris. Astringent virtues are ascribed to this medicine, which is now seldom used but in private formulæ.

Conse′rva ro′sæ. This conserve, rubbed down with water, to which is added some lemon-juice, forms an excellent drink in hæmorrhagic complaints. See *Confectio rosæ gallicæ*.

Conse′rva sci′llæ. A preparation of squills, which affords an excellent basis for an electuary, possessing expectorant and diuretic qualities.

Consiste′ntia. (From *consisto*, to abide.) The state or acme of a disease. The appearance or state of the humours and excrements.

Conso′lida. (So called, *quia consolidandi et conglutinandi vi pollet*; from its power and use in agglutinating and joining together things broken.) Comfrey.

Conso′lida au′rea. *Aurea cordis*. A name of the chamæcistus.

Conso′lida ma′jor. See *Symphytum*.

Conso′lida me′dia. See *Ajuga pyramidalis*.

Conso′lida mi′nor. See *Prunella*.

Conso′lida rega′lis. See *Delphinium consolida*.

Conso′lida sarace′nica. See *Solidago virga aurea*.

Consound. See *Symphytum*.

Consound middle. See *Ajuga pyramidalis*.

CONSTANTI′NUS, Africanus, was born at Carthage, towards the middle of the 11th century. He lived near 40 years at Babylon, and was celebrated for his knowledge of the Eastern languages. Among the sciences, medicine appears to have principally occupied his attention; and two of his works were thought deserving of being printed at Bâle, about 4½ centuries after his death, which occurred in 1087. They are thought however to have been chiefly translated from Arabian writers.

CONSTIPATION. (From *constipo*, to crowd together.) *Obstipatio*. A person is said to be costive when the alvine excrements are not expelled daily, and when the fæces are so hardened as not to receive their form from the impression of the rectum upon them.

Constricti′va. (From *constringo*, to bind together.) Styptics.

CONSTRI′CTOR. (From *constringo*, to bind together.) A name given to those muscles which contract any opening of the body.

Constri′ctor a′læ na′si. See *Depressor labii superioris alæque nasi*.

Constri′ctor a′ni. See *Sphincter ani*.

CONSTRI′CTOR I′STHMI FAU′CIUM. *Glosso-staphilinus* of Winslow, Douglas, and Cowper; and *Glosso staphilin* of Dumas. A muscle situated at the side of the entry of the fauces, that draws the *velum pendulum palati* towards the root of the tongue, which it raises at the same time, and with its fellow contracts the passage between the two arches, by which it shuts the opening of the fauces.

Constri′ctor labio′rum. See *Orbicularis oris*.

Constri′ctor mu′sculus. See *Buccinator*.

Constri′ctor o′ris. See *Orbicularis oris*.

Constri′ctor palpebra′rum. See *Orbicularis palpebrarum*.

CONSTRI′CTOR PHARY′NGIS INFE′RIOR. *Crico-pharyngeus*. *Thyro-pharyngeus* of Douglas and Winslow. *Crico-thyropharyngien* of Dumas. A muscle situated on the posterior part of the pharynx. It arises from the side of the thyroid cartilage, near the attachment of the sterno-hyoideus and thyro-hyoideus muscles; and from the cricoid cartilage, near the crico-thyroideus; it is inserted into the white line, where it joins with its fellow, the superior fibres running obliquely upwards, covering nearly one-half of the middle constrictor, and terminating in a point: the inferior fibres run more transversely, and cover the beginning of the œsophagus. Its use is to compress that part of the pharynx which it covers, and to raise it with the larynx a little upwards.

CONSTRI′CTOR PHARY′NGIS ME′DIUS. *Hyo-pharyngeus* and *cephalo-pharyngeus* of Douglas and Winslow. *Chondro-pharyngeus* of Douglas. *Syndesmo-pharyngeus* of Winslow. *Cephalo-pharyngeus* of Winslow and Douglas. *Hyo-glosso basi pharyngien* of Dumas. A muscle situated on the posterior part of the pharynx. It arises from the appendix of the os hyoides, from the cornu of that bone, and from the ligament which connects it to the thyroid cartilage; the fibres of the superior part running obliquely upwards, and covering a considerable part of the superior constrictor, terminate in a point; and it is inserted into the middle of the cuneiform process of the os occipitis, before the foramen magnum, and joined to its fellow at a white line in the middle part of the pharynx. This muscle compresses that part of the pharynx which it covers, and draws it and the os hyoides upwards.

CONSTRI′CTOR PHARY′NGIS SUPE′RIOR. *Glosso-pharyngeus*. *Mylo-pharyngeus*. *Pterygo-pharyngeus* of Douglas and Winslow, and *Pterigo syndesmo staphili pharyngien* of Dumas. A muscle situated on the posterior part of the pharynx. It arises above, from the cuneiform process of the os occipitis, before the foramen magnum, from the pterygoid process of the sphenoid bone, from the upper and under jaw, near the roots of the last dentes molares, and between the jaws. It is inserted in the middle of the pharynx. Its use is to compress the upper part of the pharynx, and to draw it forwards and upwards.

Constri′ctor vesi′cæ urina′riæ. See *Detrusor urinæ*.

Constricto′res pharyngæ′i. Muscles of the œsophagus.

Constricto′rii. Diseases attended with constriction, or spasmodic diseases.

CONSTRINGE′NTIA. (From *constringo*, to bind together.) Astringent medicines.

CONSUMPTION. (From *consumo*, to waste away.) See *Phthisis*.

Contabesce′ntia. (From *contabesco*, to pine or waste away.) An atrophy, or nervous consumption.

CONTAGION. (From *contingo*, to meet or touch each other.) *Effluvia*. *Miasma*. *Virus*. *Lues*. Infection. The very subtile particles arising from putrid substances, or from persons labouring under contagious diseases, which communicate the disease to others; as the contagion of putrid fever, the effluvia of dead animal or vegetable substances, the miasm of bogs and fens, the virus of small-pox, lues venerea, &c. &c. There does not appear to be any distinction commonly made between contagious and infectious diseases. Would it not be proper to apply the term *contagious* to those which are communicated by contact only, as the venereal disease, itch, &c.; and *infectious*, to those which may be caught through the medium of the atmosphere, &c. without contact, as putrid fever, &c.

Conte′nsio. (From *contineo*, to restrain.) It is sometimes used to express a tension or stricture.

Co′ntinens fe′bris. A continent fever, which proceeds regularly in the same tenor, without either exacerbation or remission. This rarely if ever happens.

Conti′nua fe′bris. (From *continuo*, to persevere.) A continued fever. See *Febris continua*.

Conto′rsio. (From *contorqueo*, to twist about.) A contortion, or twisting. In medicine this word has various significations, and is applied to the Iliac passion, to luxation of the vertebræ, head, &c.

Contra-apertu′ra. (From *contra*, against, and *aperio*, to open.) A counter-opening. An opening made opposite to the one that already exists.

CONTRACTILITY. A property in bodies, the effect of the cohesive power, by which their particles resume their former propinquity when the force ceases which was applied to separate them. It also denotes the power, which muscular fibres possess of shortening themselves.

CONTRACTION. (From *contraho*, to draw together.) *Contractura*. *Beriberia*. A rigid contraction of the joints. It is a genus of disease in the class *locales*, and order *dyscinesiæ* of Cullen. The species are,

1. *Contractura primaria*, from a rigid contraction of the muscles, called also obstipitas; a word that, with any other annexed, distinguishes the variety of the contraction. Of this species he forms four varieties. 1. *Contractura ab inflammatione*, when it arises from inflammation. 2. *Contractura à spasmo*, called also tonic spasm and cramp, when it depends upon spasm. 3. *Contractura ob antagonistas paraliticos*, from the antagonist muscles losing their action. 4. *Contractura ab acrimoniâ irritante*, which is induced by some irritating cause.

2. *Contractura articularis*, originating from a disease of the joint.

Contrafissu′ra. (From *contra*, against, and *findo*, to cleave.) A crack in the skull, opposite to the part on which the blow was given.

Contrahe′ntia. (From *contraho*, to contract.) Medicines which shorten and strengthen the fibres. Astringents are the only medicines of this nature.

CONTRA-INDICATION. (*Contra-indicatio*; from *contra*, against, and *indico*, to shew.) A symptom attending a disease, which forbids the exhibition of a remedy which would otherwise be employed; for instance, bark and acids are usually given in putrid fevers; but if there be difficulty of breathing, or inflammation of any viscus, they are contra-indications to their use.

Contra-luna′ris. (From *contra*, and *luna*, the moon.) An epithet given by Dietericus to a woman who conceives during the menstrual discharge.

Contra-semen. See *Artemisia Santonica*.

CONTRE COUP. (French.) A species of fracture of the skull, called in Latin *contra-fissura*, in which the fracture happens in the part opposite to where the blow was received.

Contraye′rvæ ra′dix. See *Dorstenia Contrayerva*.

CONTRAYE′RVA. (From *contra*, against, and *yerva*, poison. Span. *i. e.* a herb good against poison.) See *Dorstenia*.

Contraye′rva a′lba. *Contrayerva Germanorum*. A name for asclepias.

Contraye′rva no′va. Mexican contrayerva. This is the root of the *Psoralea pentaphylla* of Linnæus. It was introduced into Europe after the former, and is brought from Guiana as well as from Mexico. It is but little if any thing inferior to contrayerva.

Contraye′rva Virginia′na. See *Aristolochia Serpentaria*.

Contritio. The same as comminution.

CONTUSION. (From *contundo*, to knock together.) A bruise, or contused wound.

CONVALESCENCE. That space from the departure of a disease, to the recovery of the strength lost by it.

CONVALLA'RIA. (From *convallis,* a valley; named from its abounding in valleys and marshes.) The name of a genus of plants in the Linnæan system. Class, *Hexandria.* Order, *Monogynia.*

Convalla'ria maja'lis. The systematic name of the lily of the valley. *Lilium convallium. Convallaria. Maianthemum.* May-lily. The flowers of this plant. *Convallaria majalis; — scapo nudo* of Linnæus, have a penetrating bitter taste, and are given in nervous and catarrhal disorders. When dried and powdered, they prove strongly purgative. Watery or spirituous extracts made from them, given in doses of a scruple or drachm, act as gentle stimulating aperients and laxatives; and seem to partake of the purgative virtue, as well as the bitterness of aloes. The roots, in the form of tincture, or infusion, act as a sternutatory when snuffed up the nose, and as a laxative or purgative when taken internally.

Convalla'ria polygona'tum. The systematic name of Solomon's seal. *Sigillum Salomonis. Convallaria polygonatum; foliis alternis amplexicaulibus, caule ancipiti, pedunculis axillaribus subunifloris,* of Linnæus. The roots are applied externally as adstringents, and are administered internally as corroborants.

Convolu'ta superio'ra o'ssa. The superior turbinated bones of the nose.

Convolu'ta inferio'ra o'ssa. The lower turbinated bones of the nose.

CONVO'LVULUS. (From *convolvo,* to roll together.)

1. A name for the Iliac passion.
2. The name of a genus of plants in the Linnæan system, so called from their twisting round others. Class, *Pentandria.* Order, *Monogynia,* which affords the Jalapa, mechoacana, turbith, and scammony. The whole genus consists of plants containing a milky juice strongly cathartic and caustic.

Convo'lvulus America'nus. The jalap root.

Convo'lvulus canta'brica. A name for the cantabrica. *Convolvulus minimus spicæ foliis. Convolvulus linariæ folio. Convolvulus Cantabrica* of Linnæus. Lavender-leaved bind-weed. Pliny says it was discovered in the time of Augustus, in the country of the Cantabri in Spain; whence its name. It is anthelmintic and actively cathartic.

Convo'lvulus colubri'nus. The pariera brava.

Convo'lvulus jala'pa. The systematic name of the jalap plant. *Jalapium. Mechoacanna nigra.* Jalap. The plant is thus described by Linnæus. *Convolvulus jalapa: caule volubili; foliis ovatis, subcordatis, obtusis, obsolete repandis, subtus villosis; pedunculis unifloris.* It is a native of South America. In the shops, the root is found both cut into slices and whole, of an oval shape, solid, ponderous, blackish on the outside, but grey within, and marked with several dark veins, by the number of which, and by its hardness, heaviness, and dark colour, the goodness of the root is to be estimated. It has scarcely any smell, and very little taste, but to the tongue, and to the throat, manifests a slight degree of pungency. The medicinal activity of jalap resides principally, if not wholly, in the resin, which, though given in small doses, occasions violent tormina. The root powdered is a very common, efficacious, and safe purgative, as daily experience evinces; but, according as it contains more or less resin, its effects must of course vary. In large doses, or when joined with calomel, it is recommended as an anthelmintic and hydragogue. In the pharmacopœias, this root is ordered in the form of tincture and extract; and the Edinburgh College directs it also in powder, with twice its weight of crystals of tartar.

Convo'lvulus ma'jor a'lbus. See *Convolvulus sepium.*

Convo'lvulus mari'timus. The brassica maritima, or sea colewort.

Convo'lvulus mechoacan. *Mechoacannæ radix. Jalappa alba. Rhabarbarum album.* Mechoacan. The root of a species of convolvulus, *Convolvulus Mechoacan,* or *Bryonia alba Peruviana,* is brought from Mexico. It possesses aperient properties, and was long used as the common purge of this country, but is now wholly superseded by jalap.

Convo'lvulus scammo'nia. The systematic name of the scammony plant. *Scammonium. Convolvulus syriacus. Scammonium syriacum. Diagrydium.* Scammony. The plant which affords the concrete gummi-resinous juice termed scammony is the *Convolvulus scammonia; foliis sagittatis postice truncatis, pedunculis teretibus subtrifloris,* of Linnæus. It grows plentifully about Maraash, Antioch, Edlib, and towards Tripoli, in Syria. No part of the dried plant possesses any medicinal quality, but the root, which Dr. Russel administered in decoction, and found it to be a pleasant and mild cathartic. It is from the milky juice of the root that we obtain the officinal scammony, which is procured in the following manner by the peasants, who collect it in the beginning of June. Having cleared away the earth from about the root, they cut off the top in an oblique direction, about two inches below where the stalks spring from it. Under the most depending part of the slope, they fix a shell, or some other convenient receptacle, into which the milky juice gradually flows. It is left there about twelve hours, which time is sufficient for draining off the whole juice; this, however, is in small quantity, each root affording but a very few drachms. This juice from the several roots is put together, often into the leg of an old boot, for want of some more proper vessel, where, in a little time, it grows hard, and is the genuine scammony. The smell of scammony is rather unpleasant, and the taste bitterish and slightly acrid. The different proportions of gum and resin, of which it consists, have been variously stated; but, as proof spirit is the best menstruum for it, these substances are supposed to be nearly in equal parts. It is brought from Aleppo and Smyrna in masses, generally of a light shining gray colour, and friable texture; of rather an unpleasant smell, and bitterish and slightly acrid taste. The scammony of Aleppo is by far the purest. That of Smyrna is ponderous, black, and mixed with extraneous matters. Scammony appears to have been well known to the Greek and Arabian physicians, and was exhibited internally as a purgative, and externally for the itch, tinea, fixed pains, &c. It is seldom given alone, but enters several compounds, which are administered as purgatives.

Convo'lvulus se'pium. *Convolvulus major albus.* The juice of this plant, *Convolvulus sepium; foliis sagittatis postice truncatis pedunculis tetragonis, unifloris,* of Linnæus, is violently purgative, and given in dropsical affections. A poultice of the herb, made with oil, is recommended in white swellings of the knee joint.

Convo'lvulus soldane'lla. The systematic name of the sea convolvulus. *Brassica marina.* *Κραμϐη ϑαλασσια.* *Convolvulus maritimus.* *Soldanella.* Soldanella. This plant, *Convolvulus soldanella; foliis reniformibus, pedunculis unifloris,* of Linnæus, is a native of our coasts. The leaves are said to be a drastic purge. It is only used by the common people, the pharmacopœias having now substituted more safe and valuable remedies in its place.

Convo'lvulus Syri'acus. A name for the scammonium.

Convo'lvulus turpe'thum. The systematic name of the turbith plant. *Turpethum.* The cortical part of the root of a species of convolvulus, brought from the East Indies, in oblong pieces: it is of a brown or ash colour on the outside, and whitish within. The best is ponderous, not wrinkled, easy to break, and discovers to the eye a large quantity of resinous matter. When chewed, it at first imparts a sweetish taste, which is followed by a nauseous acrimony. It is considered as a purgative, liable to much irregularity of action.

CONVULSION. (*Convulsio*; from *convello*, to pull together.) *Hieranosos. Distentio nervorum.* Clonic spasm. A diseased action of muscular fibres, known by alternate relaxations, with violent and involuntary contractions of the muscular parts, without sleep. Cullen arranges convulsion in the class *neuroses,* and order *spasmi.* Convulsions are universal or partial, and have obtained different names, according to the parts affected, or the symptoms; as the *risus sardonicus,* when the muscles of the face are affected; St. Vitus's dance, when the muscles of the arm are thrown into involuntary motions, with lameness and rotations. The hysterical epilepsy, or other epilepsies, arising from different causes, are convulsive diseases of the universal kind: the muscles of the globe of the eye, throwing the eye into involuntary distortions in defiance of the direction of the will, are instances of partial convulsion. The muscles principally affected in all species of convulsions, are those immediately under the direction of the will; as those of the eyelids, eye, face, jaws, neck, superior and inferior extremities. The muscles of respiration, acting both voluntarily and involuntarily, are not unfrequently convulsed; as the diaphragm, intercostals, &c. The more immediate causes of convulsions are, 1. Either mental affection, or any irritating cause exciting a greater action in the arterial system of the brain and nerves. 2. An increase of nervous energy, which seems to hold pace or be equi potent with the increased arterial energy excited in the brain. 3. This increased energy, conveying its augmented effects, without the direction of the will, to any muscles destined to voluntary motion, over-irritates them. 4. The muscles, irritated by the increased nervous energy and arterial influx, contract more forcibly and involuntarily by their excited vis insita, conjointly with other causes, as long as the increased nervous energy continues. 5. This increased energy in the nervous system may be excited either by the mind, or by any acrimony in the blood, or other stimuli sufficiently irritating to increase the arterial action, nervous influence, and the vires insitæ of muscles. 6. After muscles have been once accustomed to act involuntarily, and with increased action, the same causes can readily produce the same effects on those organs. 7. All parts that have muscular fibres may be convulsed. 8. The sensations in the mind most capable of producing convulsions, are timidity, horror, anger, great sensibility of the soul, &c.

Convu'lsio abdo'minis. Convulsion of the muscles of the belly.

Convu'lsio cani'na. A wry mouth.

Convu'lsio cerea'lis. Cereal convulsion is a singular disorder of the spasmodic convulsive kind, not common to this country, but mentioned by Cartheuser under this title, from the peculiar tingling and formication perceived in the arms and legs. *Motus spasmodicus* of Hoffman. It is endemial in some places in Germany, but more a rural than urbanical disorder, said to arise from the use of spoiled corn.

Convu'lsio clo'nica. Convulsion with alternate relaxation.

Convu'lsio gravida'rum. Convulsion of pregnant women.

Convu'lsio habitua'lis. The chorea Sancti Viti.

Convu′lsio hemito′tonos. Convulsion approaching to tetanus.

Convu′lsio ab inani′tione. Convulsion from inanition.

Convu′lsio i′ndica. Tetanus.

Convu′lsio intermi′ttens. Convulsion occurring in paroxysms.

Convu′lsio nephra′lgica. Convulsion from stones in the kidneys.

Convu′lsio ab onani′smo. Convulsion from self-pollution.

Convu′lsio rapha′nia. Spasmodic painful disease of the joints.

Convu′lsio to′nica. Common or permanent convulsion.

Convu′lsio u′teri. Abortion.

CONY′ZA. (From κονις, dust; because its powder is sprinkled to kill fleas in places where they are troublesome.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*. Order, *Polygamia superflua*. There is some difficulty in ascertaining the plants called conyzas by the older practitioners: they are either of the genus conyza, inula, gnaphalium, erigeron, or chrysocoma.

Cony′za æthio′pica. The plant so called is most probably the chrysocoma comaurea of Willdenow, a shrub which grows wild about the Cape of Good Hope, and is cultivated in our green-houses, because it flowers the greater part of the year.

Cony′za cœru′lea. The Erigeron acre of Linnæus answers to the description of this plant.

Cony′za ma′jor. Supposed to be the inula viscosa of Linnæus.

Cony′za me′dia. See *Inula dysenterica*.

Cony′za ma′jor vulga′ris. The Inula dysenterica.

Cony′za minor. The Inu′la pulicaris of Linnæus answers to the description given of this plant in most books. Its chief use is to destroy fleas and knats.

Conyza minor flore globoso. This is the inula pulicaris of Linnæus.

Cooperto′ria. (From *co operio*, to cover over.) Cartilago thyroidea. Called also abicum.

Coo′strum. The centre of the diaphragm.

COPA′IBA. (*Copaiba, -æ*, fœm. from *copal*, the American name for any odoriferous gum, and *iba*, or *iva*, a tree.) The name given by the College of Physicians of London to the balsam of copaiva. *Balsamum Braziliense. Balsamum copaibæ. Balsamum de copaibu. Balsamum capivi.*

Copaiba is a yellow resinous juice, of a moderately agreeable smell, and a bitterish biting taste, very permanent on the tongue. The tree which affords it is the *Copaifera officinalis* of Linnæus. It is obtained by making deep incisions near its trunk, when the balsam immediately issues, and, at the proper season, flows in such abundance, that sometimes, in three hours, twelve pounds have been procured. The older trees afford the best balsam, and yield it two or three times in the same year. The balsam supplied by the young and vigorous trees, which abound with the most juice, is crude and watery, and is, therefore, accounted less valuable. While flowing from the tree, this balsam is a colourless fluid; in time, however, it acquires a yellowish tinge, and the consistence of oil; but, though by age it has been found thick, like honey, yet it never becomes solid, like other resinous fluids. By distillation in water, the oil is separated from the resin; and, in the former, the taste and smell of the balsam are concentrated. If the operation is carefully performed, about one-half of the balsam rises into the receiver, in the form of oil. The balsam unites with fixed and volatile oils, and with spirit of wine. It is given in all diseases of the urinary organs, when no inflammation is present. In gleets, and in gonorrhœa, it was once a favourite remedy, but is now disused. In diseases of the kidneys it is still employed, though less frequently than usual; and in hæmorrhoids it is occasionally trusted. The dose is from 20 to 30 drops, twice or three times a day, mixed with water, by means of an egg, or any mucilage. The balsam of copaiva is occasionally adulterated with turpentine, but its virtues are not greatly injured by the fraud.

Copaiva. See *Copaiba*.

COPAI′FERA. (From *Copaiva*, the Indian name, and *fero*, to bear.) The name of a genus of plants in the Linnæan system. Class, *Decandria*. Order, *Monogynia*.

Copai′fera officina′lis. The systematic name of the plant from which the Copaiva balsam is obtained.

COPAL. (The American name of all clear odoriferous gums.) Gum copal. This resinous substance is imported from Guinea, where it is found in the sand on the shore. It is of a yellow colour, faintly glistening, imperfectly transparent, and apt to break with a conchoidal fracture. It is tasteless, and, while cold, inodorous. It is used, dissolved in rectified spirit of wine, in laxities of the gums, with the same views as mastich.

Cope′lla. See *Cupel*.

Co′pher. A name for camphor.

Co′phos. (Κωφος, dumb.) Deaf or dumb. Also a dulness in any of the senses.

COPHO′SIS. (From κωφος, deaf.) A difficulty of hearing. It is often symptomatic of some disease. See *Dysecoea*.

COPPER, (*Cuprum, i.* neut. *quasi æs Cyprium;* so named from the island of Cyprus, whence it was formerly brought.) A metal found in the earth, in various states. It is found native, (*native copper*,) possessing the red colour, malleability, and many of its other properties; it is, however, not quite pure, but generally mixed with a minute portion of gold, or silver.

This ore is found of an indeterminate figure, in solid and compact masses; in crystals, mostly cubical; sometimes in plates and threads, which assume a variety of forms. It then is flexible. It has much metallic lustre. It is found in many parts of Europe.

Copper ores are very numerous. Copper combined with oxygen, forms *oxide of copper*, of a red or sometimes black colour. United to carbonic acid, it constitutes the blue and green copper ores, (*mountain blue, mountain green*,) &c. The compact ore of this kind is termed *malachite*. It generally exhibits a very fine grass-green, emerald-green, or apple-green colour. It is found in solid masses of an indeterminate shape. It has often a beautiful sattin-like appearance, or silky lustre.

Copper also exists mineralized by the muriatic acid, sulphuric acid, arsenic acid, &c. Copper mineralized with sulphur is called *vitreous copper ore*. Its colour is generally lead-grey. Combined with sulphur and iron, it forms all the varieties of copper pyrites. Mineralized with sulphur, arsenic, iron, and zinc, it constitutes the *brown* or *blendose copper ores*, of which there are many varieties. Copper mines are abundant in Britain, Germany, &c.

Properties of Copper.—Pure copper is of a rose-red colour, very sonorous, very tenacious, ductile, and malleable; of a considerable compactness; moderately hard and elastic. Its texture is granulated, and subject to blisters. It crystallizes in quadrilateral pyramids. Its specific gravity is between between 7.788 and 8.584. When rubbed, it emits a disagreeable odour. It melts at 27° of Wedgwood's pyrometer. At a higher temperature, it burns with a beautiful green flame. It is a good conductor of caloric, of electricity, and of galvanism. Exposed to the air it becomes brown, and at last green, by absorbing carbonic acid. When heated, it turns blue, yellow, violet, and brown. It readily fuses with phosphorus and unites to sulphur, when finely divided by mere trituration. It does not decompose water at the temperature of ignition. It is acted on by the greater number of the acids. Nitric acid acts on copper with great vehemence. Sulphuret of potash combines with it in the dry and in the humid way. It is capable of alloying with the greater number of the metals. With zinc it forms the compound metals called brass, pinchbeck, and others: with tin it forms bell-metal and bronze. It unites to the earths merely in vitrification. Liquid ammonia causes it to oxidize quickly when air is admitted. It decomposes muriate of ammonia, and red sulphuret of mercury, by heat. It is poisonous to the human constitution.

Method of obtaining Copper.— Copper is procured from its ores, by different processes, according to the nature of those ores. If they contain much sulphur, after being pounded and washed, they are roasted in the open air to dispel the sulphur. The ore is afterwards roasted once or twice more, and is melted in an open fire into a mass, called a mat of copper. In this state it still contains a large quantity of sulphur, which the workmen continue to expel by repeated roastings and fusion, till the metal acquires a certain degree of purity, and is called black copper, which is somewhat malleable, but still contains sulphur, iron, and in general some other impurities. In order to get entirely rid of these, the copper is hastily fused with three times its weight of lead. The lead unites with the copper, and expels the iron; and the rest of the metals which happen to be mixed with the copper are thus expelled. The copper is afterwards refined by keeping it heated in crucibles for a considerable time, so that it may throw up all the foreign substances it still contains in the form of scoriæ. It is examined from time to time by immersing iron rods into it, which become covered with a small quantity of copper, and its purity is judged of by the brilliant redness of these specimens.

Co'pperas. A name given to blue, green, and white vitriol.

Coprago'ga. (From κοπρος, dung, and αγω, to bring away.) *Copragogum.* The name of a gently purging electuary, mentioned by Rulandus.

Coprie'mesis. (From κοπρος, excrement, and εμεω, to vomit.) A vomiting of fæces.

Coprocri'tica. (From κοπρος, excrement, and κρινω, to separate.) Mild cathartic medicines.

Coproph'oria. (From κοπρος, excrement, and φορεω, to bring away.) A purging.

Co'pros. (Κοπρος.) The fæces, or excrements.

Coprosta'sia. (From κοπρος, fæces, and ιϛημι, to remain.) Costiveness, or a constriction of the belly.

Copta'riom. (Κοπτη, a small cake.) *Coptarium.* A medicine in the shape of a very small cake, directed for disorders of the aspera arteria and lungs, and for many other intentions, by the antients.

Co'pte. (Κοπτη, a small cake.) It was the form of a medicine used by the antients; also a cataplasm generally made of vegetable substances, and applied externally to the stomach, and internally on many occasions.

Co'pula. (*Quasi compula*; from *compello*, to restrain.) A name for a ligament.

Coque'ntia. (From *coquo*, to digest.) Medicines which promote concoction.

COR. (*Cordis*, neut.)

1. The heart. See *Heart*.
2. Gold.
3. An intense fire.

Coraci'ne. (From κοραξ, a crow; so named from its black colour.) A name for a lozenge, quoted by Galen from Asclepiades.

CORACO-BRACHIA'LIS. (From κοραξ, a crow, and βραχιον, the arm.) *Coraco-humeral* of Dumas. *Coraco-brachiæus.* A muscle, so called from its origin and insertion. It is situated on the humerus, before the scapula. It arises, tendinous and fleshy, from the fore-part of the coracoid process of the scapula, adhering, in its descent, to the short head of the biceps; inserted, tendinous and fleshy, about the middle of the internal part of the os humeri, near the origin of the third head of the triceps, called *brachialis externus,* where it sends down a thin, tendinous expansion to the internal condyle of the os humeri. Its use is to raise the arm upwards and forwards.

CORACO-HYOIDE'US. (*Coraco-hyoideus,* sc. *musculus,* κορακο-υοιδαιος: from κοραξ, a crow, and υοειδης, the bone called *hyoides.*) See *Omo-hyoideus.*

CO'RACOID. (*Coracoideus;* from κοραξ, a crow, and ειδος, resemblance; because it is shaped like the beak of a crow.) A name given to a process on the upper and anterior part of the scapula.

Côral. See *Corallium.*

CORALLI'NA. (Dim. of *corallium;* from κορη, a daughter, and αλς, the sea; because it is generated in the sea.) *Muscus maritimus.* *Corallina officinalis.* *Corallina alba.* Sea coralline, and white wormseed. A marine production, resembling a small plant without leaves, consisting of numerous brittle cretaceous substances, friable betwixt the fingers, and crackling between the teeth. Powdered, it is administered to children as an anthelmintic.

Coralli'na corsica'na. *Helmintho-corton.* *Conferva helmintho-cortos.* *Corallina rubra.* *Corallina melito-corton.* *Lemitho-corton.* Corsican worm-weed. *Fucus helmintho-corton* of De la Tourrette. This plant has gained great repute in destroying all species of intestinal worms. Its virtues are extolled by many; but impartial experimentalists have frequently been disappointed of its efficacy. The Geneva Pharmacopœia directs a syrup to be made of it.

Coralli'na melito-co'rton. See *Corallina corsicana.*

Coralli'na ru'bra. See *Corallina corsicana.*

Coralline. See *Corallina.*

Coralline, Corsican. See *Corallina Corsicana.*

Cora'llium a'lbum. A hard, white, calcareous, brittle substance; the nidus of the *Madrepora oculata.* Class, *Vermes.* Order, *Lithophyta.* It is sometimes exhibited as an absorbent earth.

CORA'LLIUM RU'BRUM. (From κορη, a daughter, and αλς, the sea; so named because it is generated in the sea.) *Acmo.* *Azur.* The red coral is mostly employed medicinally. It is a hard, brittle, calcareous substance, resembling the stalk of a plant, and is the habitation of the *Isis nobilis.* Class, *Vermes.* Order, *Zoophyta.* When powdered, it is exhibited as an absorbent earth to children; but does not appear to claim any preference to common chalk.

Corallode'ndron. (From κοραλλιον, coral, and δενδρον, a tree; resembling in hardness and colour a piece of coral.) The coral-tree of America; antivenereal.

Coralloi'des se'ptfoil. Tooth or coralwort; corroborant.

Coralloi'des fu'ngus. (From κοραλλιον, coral, and ειδος, likeness.) *Erotylus.* *Clavaria coralloides* of Linnæus. It is said to be corroborant and astringent.

Co'rchoron. (From κορη, the pupil of the eye, and κορεω, to purge; so called because it was thought to purge away rheum from the eyes.) The herb pimpernel, or chickweed.

Co'rda. See *Chordee.*

CO'RDA TY'MPANI. The portio dura of the seventh pair of nerves, having entered the tympanum, sends a small branch to the stapes, and another more considerable one, which runs across the tympanum from behind forwards, passes between the long leg of the incus and the handle of the malleus, then goes out at the same place where the tendon of the anterior muscle of the malleus enters. It is called corda tympani, because it crosses the tympanum as a cord crosses the bottom of a drum. Dr. Monro thinks, that the corda tympani is formed by the second branch of the fifth pair, as well as by the portio dura of the seventh.

CO'RDÆ WILLI'SII. See *Dura mater.*

CORDIALS. Medicines are generally so termed, which possess warm and stimulating properties, and that are given to raise the spirits.

Co'rdia my'xa. *Sebestina.* The systematic name of the Sebesten plant. *Sebesten.* Sebsten. The dark black fruit of the *cordia; foliis ovatis, supra glabris; corymbis lateralibus; calycibus decemstriatis* of Linnæus. It possesses glutinous and aperient qualities, and is exhibited in form of decoction in various diseases of the chest, hoarseness, cough, difficult respiration, &c.

Cordine'ma. (From καρα, the head, and δινεω, to move about.) A head-ache attended with a vertigo.

Cordo'lium. (From *cor,* the heart, and *dolor,* pain.) A name formerly applied to cardialgia, or heart-burn.

CORDUS, Valerius, was born in 1515, of a Hessian family. After studying in some of the German universities, he travelled through Italy, chiefly engaged in botanical researches. He died at the early age of 29, leaving several works; a "History of Plants," many of them never before described; "Annotations on Dioscorides;" a Nuremberg Dispensatory, &c.

Co′re. (Κορη.) The pupil of the eye.

Core′mata. (From κορεω, to cleanse.) Medicines for cleansing the skin.

Coriander. See *Coriandrum.*

CORIA′NDRUM. (From κορη, a pupil, and ανηρ, a man; because of its roundness, like the pupil of a man's eye; or probably so called from κορις, *cimex*, a bug, because the green herb, seed and all, stinks intolerably of bugs.) Coriander.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Digynia*.

2. The pharmacopœial name of the officinal coriander. See *Coriandrum sativum*.

Cori′andrum sati′vum. The systematic name of the plant called *coriandrum* in the pharmacopœias. *Cassibor. Corianon.* The *Coriandrum fructibus globosis*, of Linnæus. This plant is a native of the South of Europe, where, in some places, it is said to grow in such abundance as frequently to choke the growth of wheat and other grain. From being cultivated here as a medicinal plant, it has for some time become naturalized to this country, where it is usually found in corn fields, the sides of roads, and about dunghills. Every part of the plant, when fresh, has a very offensive odour, but, upon being dried, the seeds have a tolerably grateful smell, and their taste is moderately warm and slightly pungent. They give out their virtue totally to rectified spirit, but only partially to water. In distillation with water, they yield a small quantity of a yellowish essential oil, which smells strongly and pretty agreeably of the coriander.

Dioscorides asserts, that the seeds, when taken in a considerable quantity, produce deleterious effects; and, in some parts of Spain and Egypt, where the fresh herb is eaten as a cordial, instances of fatuity, lethargy, &c. are observed to occur very frequently; but these qualities seem to have been unjustly ascribed to the coriander; and Dr. Withering informs us, that he has known six drachms of the seeds taken at once, without any remarkable effect. These seeds, and indeed most of those of the umbelliferous plants, possess a stomachic and carminative power. They were directed in the infusum amarum, the infusum sennæ tartarizatum, and some other compositions of the pharmacopœias; and, according to Dr. Cullen, the principal use of these seeds is, "that infused along with senna, they more powerfully correct the odour and taste of this than any other aromatic that I have employed, and are, I believe, equally powerful in obviating the griping that senna is very ready to produce."

Coria′non. See *Coriandrum.*

Co′ris. (From κειρω, to cleave, or cut; so called because it was said to heal wounds.) The herb hypericum.

Co′ris lu′tea. *Coris legitima cretica.* The hypericum saxatile, or bastard St. John's wort.

Co′ris monspelie′nsis. This plant is intensely bitter and nauseous, but apparently, an active medicine, and employed, it is said, with success in syphilis.

CORK. The bark of the *Quercus suber* of Linnæus, formerly employed as an astringent, but now disused. It affords an acid.

CORN. *Clavus.* A hardened portion of cuticle, produced by pressure: so called because a piece can be picked out like a corn of barley. Corns are sometimes connected with the periosteum.

Cornachi′ni pu′lvis. Scammony, antimony, and cream of tartar.

CORNARIUS, John, was born in Upper Saxony, in the year 1500. According to Haller his real name was Haguenbot, or Hanbut. He is said to have been led to the study of medicine from the delicacy of his own constitution. He graduated at Padua, after attending several other universities. Besides translating Hippocrates, and some other Greek writers into Latin, he was author of several works on medicine; and is said to have had an extensive practice. He died in 1558, leaving a son, Diomede, who succeeded him, and was afterwards professor of medicine at Vienna, and physician to Maximilian II.

CORNARO, Lewis, of a noble Venetian family, was born in 1467. Having impaired his constitution by a debauched and voluptuous life, and brought on at last a severe illness, on recovering from this, at the age of more than 40, he adopted a strict, abstemious regimen, limiting himself to twelve ounces of solid food, and fourteen of wine, daily; which quantity he rather diminished in the latter part of his life. He carefully avoided also the extremes of heat or cold, with all violent exercise; and took care to live in a pure dry air. He thus preserved a considerable share of health and activity to the great age of 98. His wife, by whom he had an only child, a daughter, when they were both advanced in years, survived him, and attained nearly the same period. When he was 83, he published a short treatise in commendation of temperance, which has been repeatedly translated, and printed in every country of Europe. He then states himself to have been able to mount his horse, without assistance, from any rising ground. He wrote three other discourses on similar subjects at subsequent periods, the last only three years before his death. The best English translation is said to be that of 1779.

CO'RNEA OPA'CA. The sclerotic membrane of the eye is so called, because it is of a horny consistence and opake. See *Sclerotic coat*.

CO'RNEA TRANSPA'RENS. *Sclerotica ceratoides*. The transparent portion of the sclerotic membrane, through which the rays of light pass, is so called, to distinguish it from that which is opake. See *Sclerotic coat*.

Corne'sta. A chemical retort.

Cornflower. See *Centaurea Cyanus*.

Corni'cula. (From *cornu*, a horn.) A cupping instrument, made of horn.

Cornicula'ris. (From *cornu*, a horn.) Shaped like a horn; the coracoid process.

Corn-sallad. This is the *Valeriana locusta* of Linnæus. It is cultivated in our gardens, and eaten amongst the early sallads. It is a very wholesome succulent plant, possessing antiscorbutic and gently aperient virtues.

CO'RNU AMMO'NIS. *Cornu arietis*. When the pes hippocampi of the human brain is cut transversely through, the cortical substance is so disposed as to resemble a ram's horn. This is the true cornu ammonis, though the name is often applied to the *pes hippocampi*.

CO'RNU ARI'ETIS. See *Cornu ammonis*.

CO'RNU. *Cornu cervi*. Hartshorn. The horns of several species of stag, as the *cervus alces*, *cervus dama*, *cervus elaphus*, and *cervus taranda*, are used medicinally. Boiled, they impart to the water a nutritious jelly, which is frequently served at table. Hartshorn jelly is made thus:—Boil half a pound of the shavings of hartshorn, in six pints of water, to a quart; to the strained liquor add one ounce of the juice of lemon, or of Seville orange, four ounces of mountain wine, and half a pound of sugar; then boil the whole to a proper consistence. The chief use of the horns is for calcination, and to afford the *liquor volatilis cornu cervi* and sub-carbonate of ammonia.

Co'rnu ce'rvi calcina'tum. See *Cornu ustum*.

Co'rnu u'stum. Burn pieces of hartshorn in an open fire, till they become thoroughly white; then powder, and prepare them in the same manner, as is directed for chalk. Burnt hartshorn shavings possess absorbent, antacid, and adstringent properties, and are given in the form of decoction, as a common drink in diarrhœas, pyrosis, &c.

CO'RNUA. Warts. Horny excrescences, which mostly form on the joints of the toes. Similar diseased productions have been known to arise on the head, and other parts.

Co'rnua u'teri. *Plectenæ*. In comparative anatomy, the horns of the womb; the womb being in some animals triangular, and its angles resembling horns.

Cornumu'sa. A retort.

CO'RNUS. 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*. Order, *Monogynia*.

2. The pharmacopœial name of the cornel-tree. *Cornus sanguinea* of Linnæus. The fruit is moderately cooling and astringent.

Cornu'ta. (From *cornu*; from its resemblance to a horn.) A retort.

Coro'na cilia'ris. The ciliar ligament.

CORO'NA GLA'NDIS. The margin of the glans penis.

Coro'na imperia'lis. A name for crown-imperial. The Turks use this plant as an emetic. The whole plant is considered poisonous.

Coro'na re'gia. The melilotus.

Coro'na so'lis. Sun-flower. Called also chimalati. The *Helianthus annuus* of Linnæus. It has been noticed as heating, and an agreeable food. The seeds are made into bread.

Coro'na ve'neris. Venereal blotches on the forehead are so termed.

CORO'NAL SU'TURE. (From *corona*, a crown, or garland; so named because the antients wore their garlands in its direction.) *Satura coronalis*. *Sutura arcualis*. The suture of the head, that extends from one temple across to the other, uniting the two parietal bones with the frontal.

Corona'rius stoma'chicus. Part of the eighth pair of nerves.

CORONARY VESSELS. *Vasa coronaria*. The arteries and veins of the heart; also others belonging to the stomach. The term coronary is here given from *corona*, a crown, surrounding any part in the manner of a crown.

CORONARY LIGAMENTS. (From *corona*, a crown.) Ligaments uniting the radius and ulna. The term ligamentum coronarium is also applied to a ligament of the liver.

CORO'NE. (Κορωνη, a crow; so named from its supposed likeness to a crow's bill.) The acute process of the lower jaw-bone.

CORONOID. (*Coronoideus*; from κορωνη, a crow, and ειδος, likeness.) Processes of bones are so called, that have any resemblance to a crow's beak, as *coronoides apophysis ulnæ*, *coronoides apophysis maxillæ*.

Corono'pus. (From κορωνη, a carrion crow, and πους, foot; the plant being said to resemble a crow's foot.) See *Plantago*.

CO'RPORA ALBICA'NTIA. Corpora albicantia Willisii.

CO'RPORA CAVERNO'SA CLITO'RIDIS. Two hollow crura, forming the clitoris.

CO'RPORA CAVERNO'SA PE'NIS. Two spongy bodies that arise, one from each ascending portion of the ischium, and form the whole bulk of the penis above the urethra, and terminate obtusely behind its glans. See *Penis*.

CO'RPORA FIMBRIA'TA. The

flattened terminations of the posterior crura of the fornix of the brain, which turn round into the inferior cavity of the lateral ventricle, and end in the *pedes hippocampi.*

Co′rpora lobo′sa. Part of the cortical part of the kidney.

Co′rpora nerveo-spongio′sa. The corpora cavernosa penis.

Co′rpora nervo′sa. The corpora cavernosa clitoridis.

CO′RPORA OLIVA′RIA. The two external prominences of the medulla oblongata, that are shaped somewhat like an olive.

CO′RPORA PYRAMIDA′LIA. Two internal prominences of the medulla oblongata, which are more of a pyramidal shape than the former.

CO′RPORA QUADRIGE′MINA. See *Tubercula quadrigemina.*

CO′RPORA STRIA′TA. So named from their appearance. See *Cerebrum.*

CO′RPUS ANNULA′RE. A synonym of pons Varolii. See *Pons Varolii.*

CO′RPUS. The body. Many parts and substances are also distinguished by this name: as *corpus callosum, corpus luteum,* &c. See also *Body.*

CO′RPUS CALLO′SUM. *Commissura magna cerebri.* The white medullary part joining the two hemispheres of the brain, and coming into view under the falx of the dura mater when the hemispheres are drawn from each other. On the surface of the *corpus callosum* two lines are conspicuous, called the *raphe.*

Co′rpus glandulo′sum. The prostate gland.

CO′RPUS LU′TEUM. The granulous papilla which is found in that part of the ovarium of females, from whence an ovum has proceeded; hence their presence determines that the female has been impregnated; and the number of the *corpora lutea* corresponds with the number of impregnations. It is, however, asserted by a modern writer, that *corpora lutea* have been detected in young virgins, where no impregnations could possibly have taken place.

Co′rpus muco′sum. See *Rete mucosum.*

CO′RPUS PAMPINIFO′RME. (*Pampiniformis;* from *pampinus,* a tendril, and *forma,* likeness, resembling a tendril.) *Corpus pyramidale.* Applied to the spermatic chord, and thoracic duct; also to the plexus of veins surrounding the spermatic artery in the cavity of the abdomen.

Co′rpus reticula′re. See *Rete mucosum.*

CO′RPUS SESAMOIDE′UM. A little prominence at the entry of the pulmonary artery.

CO′RPUS SPONGIO′SUM URE′THRÆ. *Substantia spongiosa urethræ. Corpus spongiosum penis.* This substance originates before the prostate gland, surrounds the urethra, and forms the *bulb;* then proceeds to the end of the corpora cavernosa, and terminates in the *glans penis,* which it forms.

Co′rpus varico′sum. The spermatic chord.

Corra′go. (From *cor,* the heart; it being supposed to have a good effect in comforting the heart.) See *Borago.*

Co′rre. (From κειρω, to shave.) The temples. That part of the jaws where the beard grows, and which it is usual to shave.

CORROBORANTS. (*Corroborantia,* sc. *medicamenta.*) Medicines, or whatever gives strength to the body, as bark, wine, beef, cold bath, &c. See *Tonics.*

Corrosive sublimate. See *Hydrargyri oxymurias.*

CORROSIVES. (*Corrosiva,* sc. *medicamenta;* from *corrodo,* to eat away.) See *Escharotics.*

CORRUGA′TOR SUPERCI′LII. (From *corrugo,* to wrinkle.) *Musculus supercilii* of Winslow. *Musculus frontalis verus, seu corrugator coiterii* of Douglas, and *Cutaneo sourcillier* of Dumas. A small muscle situated on the forehead. When one muscle acts, it is drawn towards the other, and projects over the inner canthus of the eye. When both muscles act, they pull down the skin of the forehead, and make it wrinkle, particularly between the eye-brows.

CO′RTEX. (*-ticis,* m. or f.) This term is generally, though improperly, given to the Peruvian bark. It applies to any rind, or bark.

Co′rtex angeli′næ. The bark of a tree growing in Grenada. A decoction of it is recommended as a vermifuge. It excites tormina, similar to jalap, and operates by purging.

Co′rtex angustu′ræ. See *Cuspariæ.*

Co′rtex antiscorbu′ticus. The canella alba.

Co′rtex aroma′ticus. The canella alba.

Co′rtex bela-aye. See *Bela-aye cortex.*

Co′rtex cane′llæ malaba′ricæ. See *Laurus cassia.*

Co′rtex cardina′lis de Lu′go. The Peruvian bark was so called, because the Cardinal Lugo had testimonials of above a thousand cures performed by it in the year 1653.

Co′rtex ce′rebri. The cortical substance of the brain.

Co′rtex chi′næ re′gius. See *Cinchona.*

Co′rtex chi′næ suriname′nsis. This bark is remarkably bitter, and preferable to the other species in intermittent fevers.

Co′rtex chinchi′næ. See *Cinchona.*

Co′rtex eluthe′riæ. See *Croton cascarilla.*

Co′rtex geoffroy′æ jamaice′nsis. See *Geoffroya Jamaicensis.*

Co′rtex la′vola. The bark bearing this name is supposed to be the produce of the tree which affords the *anisum stellatum.* Its virtues are similar.

Co′rtex magella′nicus. See *Wintera aromatica.*

Co′rtex massoy. The produce of New Guinea, where it is beaten into a pultaceous mass with water, and rubbed upon the abdomen to allay tormina of the bowels. It partakes of the smell and flavour of cinnamon.

Co′rtex pa′trum. The Peruvian bark.

Co′rtex Peruvia′nus. See *Cinchona.*

Co′rtex Peruvia′nus fla′vus. See *Cinchona.*

Co′rtex Peruvia′nus ru′ber. See *Cinchona.*

Co′rtex pocgerebæ. This bark is sent from America; and is said to be serviceable in diarrhœas, dysenteries, and hepatic fluxes.

Co′rtex qua′ssiæ. See *Quassia.*

Co′rtex wintera′nus. See *Wintera aromatica.*

CO′RTICAL. Cineritious substance. The external substance of the brain is of a darker colour than the internal, and surrounds the medullary substance, as the bark does the tree; hence it is termed *cortical.* See also *Kidneys.*

Cortu′sa. The plant self-heal; bear's ear; sanicle. It is expectorant.

Co′ru cana′rica. A quince-like tree of Malabar; it is antidysenteric.

CO′RYLUS. (Derivation uncertain; according to some, from καρυα, a walnut.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia.* Order, *Polyandria.*

2. The pharmacopœial name of the hazel-tree. See *Corylus avellana.*

Co′rylus ave′llana. The hazel-nut tree. The nuts of this tree are much eaten in this country; they are hard of digestion, and often pass the bowels very little altered; if, however, they are well chewed, they give out a nutritious oil. An oil is also obtained from the wood of this tree, *Corylus avellana stipulis ovatis, obtusis,* of Linnæus: which is efficacious against the tooth-ache, and is said to kill worms.

Co′ryphe. (Κορυφη.) The vertex of the head. The inner parts of the nails.

CORY′ZA. (*Coryza,* κορυζα: from καρα, the head, and ζεω, to boil.) An increased discharge of mucus from the nose. See *Catarrh.*

Cory′za catarrha′lis. A catarrh from cold.

Cory′za febrico′sa. A catarrh with fever.

Cory′za phlegmatorrha′gia. A catarrh, with much discharge of mucus.

Cory′za purule′nta. A catarrh, with discharge of matter.

Cory′za variolo′sa. A catarrh accompanying small-pox.

Cory′za virule′nta. A catarrh, with discharge of acrid mucus.

Coscu′lia. The grains of kermes.

COSME′TIC. A term applied to remedies against blotches and freckles.

Co′smos. *Rythmus.* A regular series. In Hippocrates it is the order and series of critical days.

Co′ssis. *Cossi.* A worm that breeds in wood: also a little tubercle in the face, like the head of a worm.

Co′ssum. A malignant ulcer of the nose mentioned by Paracelsus.

CO′STA. (*A custodiendo*; because the ribs surround and defend the vital parts.) A rib. The ribs are four-and-twenty in number, twelve on each side of the thorax. See *Ribs.*

Co′sta pulmona′ria. *Costa herba.* A name of the herb hawkweed.

Costo-hyoide′us. (From *costa,* a rib, and *hyoideus,* belonging to the hyoidal bone.) A muscle so named from its origin and insertion. See *Omo-hyoideus.*

CO′STUS. (From *kasta,* Arabian.) The name of a genus of plants in the Linnæan system. Class, *Monandria.* Order, *Monogynia.*

Co′stus ama′rus. See *Costus arabicus.*

Co′stus ara′bicus. *Costus indicus, amarus, dulcis, orientalis.* Sweet and bitter costus. The root of this tree, *Costus arabicus* of Linnæus, possesses bitter and aromatic virtues, and is considered as a good stomachic. Formerly there were two other species, the *bitter* and *sweet,* distinguished for use. At present, the Arabic only is known, and that is seldom employed. It is, however, said to be stomachic, diaphoretic, and diuretic.

Co′stus cortico′sus. The canella alba.

Co′stus horto′rum mi′nor. The ageratum.

Co′stus ni′gra. The artichoke.

Co′style. (Κοτυλη, the name of an old measure.) The socket of the hip-bone.

Cotaro′nium. A word coined by Paracelsus, implying a liquor into which all bodies, and even their elements, may be dissolved.

Co′tis. (From κοτλη, the head.) The back part of the head; sometimes the hollow of the neck.

Co′tula fœ′tida. (*Cotula,* dim. of *cos,* a whetstone, from the resemblance of its leaves to a whetstone; or from κοτυλη, a hollow.) Stinking chamomile. See *Anthemis cotula.*

COTYLOID CAVITY. (*Cotyloides;* from κοτυλη, the name of an old measure, and ειδος, resemblance.) The acetabulum. See *Innominatum os.*

Cotyloi′des. See *Cotyloid cavity.*

COUCHING. A surgical operation that consists in removing the opaque lens out of the axis of vision, by means of a needle, constructed for the purpose. There are two couching needles, which now seem to be preferred to all others; the one used by Mr.

Hey, and that employed by Professor Scarpa.

Couch-grass. See *Triticum repens.*

COUGH. *Tussis.* A sonorous concussion of the thorax, produced by the sudden expulsion of the inspired air.

Co′um. The meadow-saffron.

COUNTER-OPENING. *Contra-apertura.* An opening made in any part of an abscess opposite to one already in it. This is often done in order to afford a readier egress to the collected pus.

Coup de soleil. (French.) An erysipelas or apoplexy, or any affection produced instantaneously from a scorching sun.

Cou′rap. (Indian.) A distemper very common in Java, and other parts of the East Indies, where there is a perpetual itching and discharge of matter. It is a herpes on the axilla, groins, breast, and face.

Cou′rbaril. The tree which produces the gum anime. See *Anime.*

Couro′ndi. An evergreen tree of India, said to be antidysenteric.

Couroy moe′lli. A shrub of India, said to be antivenomous.

Cou′scous. An African food, much used about the river Senegal. It is a composition of the flour of millet, with some flesh, and what is there called lalo.

Covola′m. The *Cratæva marmelos* of Linnæus, whose fruit is astringent whilst unripe; but when ripe of a delicious taste. The bark of the tree strengthens the stomach, and relieves hypochrondriac languors.

Cowhage. See *Dolichos.*

Cow-itch. See *Dolichos.*

COWPER, William, was born about the middle of the 17th century, and became distinguished as a surgeon and anatomist in this metropolis. His first work, entitled "Myotomia Reformata," in 1694, far excelled any which preceded it on that subject in correctness, though since surpassed by Albinus. Three years after, he published at Oxford "the Anatomy of Human Bodies," with splendid plates, chiefly from Bidloo; but forty of the figures were from drawings made by himself; he added also some ingenious and useful anatomical and surgical observations. Having been accused of plagiarism by Bidloo, he wrote an apology, called "Eucharistia;" preceded by a description of some glands, near the neck of the bladder, which have been called by his name. He was also author of several communications to the Royal Society, and some observations inserted in the anthropologia of Drake. He died in 1710.

COWPER'S GLANDS. (*Cowperi glandulæ*; named from Cowper, who first described them.) Three large muciparous glands of the male, two of which are situated before the prostate gland under the accelerator muscles of the urine, and the third more forward, before the bulb of the urethra. They excrete a fluid, similar to that of the prostate gland, during the venereal orgasm.

Cowpe′rigla′ndulæ. See *Cowper's glands.*

CO′XA. The ischium is sometimes so called, and sometimes the os coccygis.

Coxe′ndix. (From *coxa*, the hip.) The ischium; the hip-joint.

CRABLOU′SE. A species of pediculus which infests the axillæ and pudenda.

Crab-yaws. A name in Jamaica for a kind of ulcer on the soles of the feet, with callous lips, so hard that it is difficult to cut them.

CRA′MBE. (Κραμϐη, the name given by Dioscorides, Galen, and others, to the cabbage; the derivation is uncertain.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia.* Order, *Siliculosa.* Cabbage.

Cra′mbe mari′tima. The systematic name for the sea-cole.

CRAMP. (From *krempen*, to contract. Germ.) A spasm of a muscle or muscles.

Cranesbill, bloody. See *Geranium sanguineum.*

CRA′NIUM. (Κρανιον, *quasi* καρανιον; from καρα, the head.) The skull or superior part of the head. See *Caput.*

Crante′res. (From κραινω, to perform.) A name given to the sapientiæ dentes and other molares, from their office of masticating the food.

CRA′PULA. (Κραιπυλα.) A surfeit; drunkenness.

CRA′SIS. (From κεραννυμι, to mix.) Mixture. A term applied to the humours of the body, when there is such an admixture of their principles as to constitute a healthy state: hence, in dropsies, scurvy, &c. the crasis, or healthy mixture of the principles of the blood, is said to be destroyed.

Cra′spedon. (Κρασπεδον, the hem of a garment; from κρεμαω, to hang down, and πεδον, the ground.) A relaxation of the uvula, when it hangs down in a thin, long membrane, like the hem of a garment.

CRASSAME′NTUM. (From *crassus*, thick.) See *Blood.*

Cra′ssula. (From *crassus*, thick: so named from the thickness of its leaves.) See *Sedum telephium.*

CRATÆ′GUS. (From κρατος, strength: so called from the strength and hardness of its wood.) The wild service-tree, whose virtues are astringent.

Crati′cula. (From *crates*, a hurdle.) The bars or grate which covers the ash-hole in a chemical furnace.

CRATON, John, called also Crafftheim, was born at Breslaw in 1519. He was intended for the church, but preferring the study of medicine went to graduate at Padua, and then settled at Breslaw. But after a few years he was called to Vienna, and made physician and aulic counsellor to the Emperor Ferdinand I.: which offices also he held under the two succeeding emperors, and died in 1585. His works were numerous: the principal are, "A Commentary on Syphilis;" "A Treatise on Contagious Fever;" another on "Therapeutics;" and seven volumes of Epistles and Consultations.

Cream of tartar. See *Potassæ supertartras.*

CREMA′STER. (From κρεμαω, to suspend.) A muscle of the testicle, by which it is suspended, and drawn up and compressed, in the act of coition. It arises from Poupart's ligament, passes over the spermatic cord, and is lost in the cellular membrane of the scrotum, covering the testicles.

Cre′mnus. (From κρημνος, a precipice, or shelving place.) The lips of an ulcer are so called. Also the labium pudendi.

CRE′MOR. Cream. Any substance floating on the top, and skimmed off.

CRE′PITUS. (From *crepo*, to make a noise.) A puff or little noise: the crackling made by the joints when there is a defect of synovia.

Cre′pitus lu′pi. See *Lycoperdon bovista.*

Cress, water. See *Sisymbrium nasturtium.*

CRE′TA. *Carbonas calcis friabilis.* Chalk. Carbonate of lime. Pure chalk is a neutral compound of carbonic acid and lime. See *Creta præparata.*

Cre′ta præpara′ta. Take of chalk a pound; add a little water, and rub it to a fine powder. Throw this into a large vessel full of water; then shake them, and after a little while pour the still turbid liquor into another vessel, and set it by that the powder may subside; lastly, pouring off the water, dry this powder. Prepared chalk is absorbent, and possesses antacid qualities: it is exhibited in form of electuary, mixture, or bolus, in pyrosis, cardialgia, diarrhœa, acidities of the primæ viæ, rachitis, crusta lactea, &c. and is said by some to be an antidote against white arsenic.

Cretaceous acid. See *Carbonic acid.*

Crete, dittany of. See *Origanum dictamnus.*

CRIBRIFO′RMIS. (From *cribrum*, a sieve, and *forma*, likeness; because it is perforated like a sieve.) See *Ethmoid bone.*

CRI′CO. Names compounded of this word belong to muscles which are attached to the cricoid cartilage.

CRI′CO-ARYTÆNOIDE′US LATERA′LIS. *Crico-lateri arithenoidien* of Dumas. A muscle of the glottis, that opens the *rima* by pulling the ligaments from each other.

CRI′CO-ARYTÆNOIDE′US POSTI′CUS. *Crico creti arithenoidien* of Dumas. A muscle of the glottis, that opens the *rima glottidis* a little, and by pulling back the arytænoid cartilage, stretches the ligament so as to make it tense.

Cri′co-pharynge′us. See *Constrictor pharyngis inferior.*

CRI′CO-THYROIDE′US. *Crico-thyroidien* of Dumas. The last of the second layer of muscles between the os hyoides and trunk, that pulls forwards and depresses the thyroid cartilage, or elevates and draws backwards the cricoid cartilage.

CRICOI′DES. (From κρικος, a ring, and ειδος, resemblance.) A round ring like cartilage of the larynx is called the cricoid. See *Larynx.*

Crimno′des. (From κριμνον, bran.) A term applied to urine, which deposits a sediment like bran.

Crina′tus. (From κρινον, the lily.) A term given to a suffumigation mentioned by P. Ægineta, composed chiefly of the roots of lilies.

Cri′nis. The hair. See *Capillus.*

Crinomy′ron. (From κρινον, a lily, and μυρον, ointment.) An ointment composed chiefly of lilies.

CRINO′DES. (From *crinis*, the hair.) *Comedones.* Collections of a sebaceous fluid in the cutaneous follicles upon the face and breast, which appear like black spots, and when pressed out, look like small worms, or, as they are commonly called, maggots.

Crio′genes. An epithet for certain troches, mentioned by P. Ægineta, and which he commends for cleansing sordid ulcers.

Cripso′rchis. (From κρυπτω, to conceal, and *ορχις*, a testicle.) Having the testicle concealed, or not yet descended into the scrotum.

CRI′SIS. (From κρινω, to judge.) The judgment. The sudden change of symptoms in acute diseases, from which the recovery or death is prognosticated or judged of.

Crispatu′ra. (From *crispo*, to curl.) A spasmodic contraction, or curling of the membranes and fibres.

CRI′STA. (*Quasi cerista*; from κερας, a horn, or *carista*: from καρα, the head, as being on the top of the head.) Any thing which has the appearance of a crest, or the comb upon the head of a cock, as crista clitoridis, the nympha. Also a tubercle about the anus; so called from its form.

CRI′STA GA′LLI. An eminence of the ethmoid bone, so called from its resemblance to a cock's comb. See *Ethmoid bone.*

Cri′thamum. See *Crithmum.*

Crithe′rion. (From κρινω, to judge.) The same as crisis.

Cri′the. (Κριθη.) Barley. A stye or tumour on the eyelid, in the shape and of the size of a barley-corn.

CRI′THMUM. (From κρινω, to secrete;

so named from its supposed virtues in promoting a discharge of the urine and menses.) Samphire or sea-fennel.

Cri′thmum mari′timum. The Linnæan name of the samphire or sea-fennel. *Crithmum.* It is a low perennial plant, and grows about the sea-coast in several parts of the island. It has a spicy aromatic flavour, which induces the common people to use it as a pot-herb. Pickled with vinegar and spice it makes a wholesome and elegant condiment which is in much esteem.

Critho′des. (From *κριθη*, barley, and *ειδος*, resemblance.) Resembling a barley-corn. It is applied to small protuberances.

CRI′TICAL. Determining the event of a disease. Many physicians have been of opinion, that there is something in the nature of fevers which generally determines them to be of a certain duration; and, therefore, that their terminations, whether salutary or fatal, happen at certain periods of the disease, rather than at others. These periods, which were carefully marked by Hippocrates, are called *critical days.* The critical days, or those on which we suppose the termination of continued fevers especially to happen, are the third, fifth, seventh, ninth, eleventh, fourteenth, seventeenth, and twentieth.

Crocidi′xis. (From *κροκιδιζω*, to gather wool.) A fatal symptom in some diseases, where the patient gathers up the bed-clothes, and seems to pick up substances from them.

Cro′cinum. (From *κροκος*, saffron.) Oil of saffron, or a mixture of oil, myrrh, and saffron.

Croco′des. (From *κροκος*, saffron; so called from the quantity of saffron they contain.) A name of some old troches.

Crocoma′gma. (From *κροκος*, saffron, and *μαγμα*, the thick oil or dregs.) A troch made of oil of saffron and spices.

CRO′CUS. (*Κροκος* of Theophrastus. The story of the young Crocus, turned into this flower, may be seen in the fourth book of Ovid's Metamorphoses. Some derive this name from *κροκη*, or *κροκις*, a thread; whence the stamens of flowers are called *κροκιδες*. Others, again, derive it from *Coriscus,* a city and mountain of Cilicia, and others from *crokin,* Chald.) Saffron.

1. The name of a genus of plants in the Linnæan system. Class, *Triandria.* Order, *Monogynia.* Saffron.

2. The pharmacopœial name of the prepared stigmata of the *Crocus sativus, spatha univalvi radicali, corollæ tubo longissimo,* of Linnæus. Saffron has a powerful, penetrating, diffusive smell, and a warm, pungent, bitterish taste. Many virtues were formerly attributed to this medicine, but little confidence is now placed in it. The Edinburgh College directs a tincture, and that of London a syrup of this drug.

3. A term given by the older chemists to several preparations of metallic substances, from their resemblance: thus, *crocus martis, crocus veneris.*

Cro′cus antimo′nii. *Crocus metallorum.* This preparation is a sulphuretted oxide of antimony. It possesses emetic and drastic cathartic powers, producing a violent diaphoresis afterwards.

Cro′cus Germa′nicus. See *Carthamus.*

Cro′cus I′ndicus. See *Curcuma.*

Cro′cus ma′rtis. Green vitriol exposed to fire till red.

Cro′cus metallo′rum. See *Crocus antimonii.*

Cro′cus officina′lis. See *Crocus sativus.*

Cro′cus sarace′nicus. See *Carthamus.*

Cro′cus sati′vus. See *Crocus.*

Cro′cus ve′neris. Copper calcined to a red powder.

Cro′mmyon. (*Παρα το τας κορας μυειν*, because it makes the eyes wink.) An onion.

Crommyoxyre′gma. (From *κρομμυον*, an onion, *οξυς*, acid, and *ρηγνυμι*, to break out.) An acid eructation accompanied with a taste resembling onions.

CROONE, William, was born in London, where he settled as a physician, after studying at Cambridge. In 1659 he was chosen rhetoric professor of Gresham College, and soon after register of the Royal Society, which then assembled there. In 1662 he was created doctor in medicine by mandate of the king, and the same year elected fellow of the Royal Society, and of the College of Physicians. In 1670 he was appointed lecturer on anatomy to the Company of Surgeons. On his death in 1684 he bequeathed them 100*l.*; his books on Medicine to the College of Physicians, as also the profits of a house, for Lectures, to be read annually, on Muscular Motion; and donations to seven of the colleges at Cambridge, to found Mathematical Lectures. He left several papers on philosophical subjects, but his only publication was a small tract "De Ratione Motus Musculorum."

Crota′phica arte′ria. The tendon of the temporal muscle.

Crotaphi′tes. (*Crotaphites,* sc. *musculus;* from *κροταφος*, the temple.) See *Temporalis.*

Crota′phium. (From *κροτεω*, to pulsate; so named from the pulsation which in the temples is eminently discernible.) *Crotaphos. Crotaphus.* A pain in the temples.

Cro′taphos. See *Crotaphium.*

Cro′taphus. See *Crotaphium.*

CROTCHET. A curved instrument with a sharp hook to extract the fœtus.

CRO′TON. (From *κροτεω*, to beat.)

1. An insect called a tick, from the

noise it makes by beating its head against wood.

2. A name of the ricinus or castor-oil-berry, from its likeness to a tick.

3. The name of a genus of plants in the Linnæan system. Class, *Monoecia*. Order, *Monadelphia*.

Cro′ton benzo′e. Gum-Benjamin was formerly so called.

Cro′ton cascari′lla. The systematic name of the plant which affords the Cascarilla bark. *Cascarilla. Chocarilla. Elutheria. Eluteria.* The tree that affords the cascarilla bark, is the *Croton cascarilla* of Linnæus. The bark comes to us in quills, covered upon the outside with a rough, whitish matter, and brownish on the inner side; exhibiting, when broken, a smooth, close, blackish-brown surface. It has a light agreeable smell, and a moderately bitter taste, accompanied with a considerable aromatic warmth. It is a very excellent tonic, adstringent, and stomachic, and is deserving of a more general use than it has hitherto met with.

Cro′ton lacci′ferum. The systematic name of the plant upon which gum-lac is deposited.

Cro′ton ti′glium. The name of the tree which affords the pavana wood, and tiglia seeds.

1. *Lignum pavanæ. Lignum pavanum. Lignum moluccense. Croton; foliis ovatis glabris acuminatis serratis, caule arboreo* of Linnæus. The wood is of a light spongy texture, white within, but covered with a greyish bark; and possesses a pungent, caustic taste, and a disagreeable smell. It is said to be useful as a purgative in hydropical complaints.

2. *Grana tiglia. Grana tilli. Grana tiglii.* The grana tilia are seeds of a dark grey colour, the produce of the *Croton tiglium* of Linnæus, in shape very like the seed of the *ricinus communis*. They abound with an oil which is far more acrid and purgative than castor-oil.

Cro′ton tincto′rium. The systematic name of the lacmus plant. *Bezetta cœrulea.* This plant yields the *Succus heliotropii. Lacmus seu tornæ. Lacca cœrulea. Litmus.* It is the *Croton tinctorium; foliis rhombeis repandis, capsulis pendulis, caule herbaceo*, of Linnæus. It is much used by chemists as a test.

Croto′ne. (From κροτον, the tick.) A fungus on trees produced by an insect like a tick; and by metaphor applied to tumours and small fungous excrescences on the periosteum.

Croup. See *Cynanche.*

Crou′sis. (From κρουω, to beat, or pulsate.) Pulsation.

Crou′smata. (From κρουω, to pulsate.) Rheums or defluxions from the head.

Crowfoot. See *Ranunculus.*

Crowfoot cranesbill. See *Geranium pratense.*

CRUCIAL. Some parts of the body are so called when they cross one another, as the crucial ligaments of the thigh.

Crucia′lis. Cross-like. Mugweed or crosswort.

CRUCIBLE. (*Crucibulum*, from *crucio*, to torment; so named, because, in the language of old chemists, metals are tormented in it, and tortured, to yield up their powers and virtues.) A chemical vessel made mostly of earth to bear the greatest heat. They are of various shapes and composition.

Cru′ditas. (From *crudus*, raw.) It is applied to undigested substances in the stomach, and humours in the body unprepared for concoction.

CRUICKSHANK, William, was born at Edinburgh, in 1746. He was intended for the church, and made great proficiency in classical learning; but, showing a partiality to medicine, he was placed with a surgeon at Glasgow. In 1771, he came to London, and was soon after made librarian to Dr. William Hunter; and, on the secession of Mr. Hewson, became assistant, and then joint lecturer in anatomy, with the Doctor. He contributed largely to enrich the Museum, particularly by his curious injections of the lymphatic vessels. He published, in 1786, a work on this subject, which is highly valued for its correctness. In 1795, he communicated to the Royal Society an Account of the Regeneration of the Nerves; and the same year published a pamphlet on Insensible Perspiration; and in 1797, an Account of Appearances in the Ovaria of Rabbits in different Stages of Pregnancy. He died in 1800.

Cru′nion. (From κρουνος, a torrent.) A medicine mentioned by Aetius, and named from the violence of its operation as a diuretic.

CRU′OR. The red part of the blood. See *Blood.*

CRU′RA. The plural of *crus*, a leg or root; applied to some parts of the body from their resemblance to a leg or root: thus *crura cerebri, crura cerebelli*, the *crura* of the diaphragm, &c. &c.

Cru′ra clito′ridis. See *Clitoris.*

Cru′ra medu′llæ oblonga′tæ. The roots of the medulla oblongata.

CRURÆ′US. (From *crus*, a leg; so named, because it covers almost the whole foreside of the upper part of the leg or thigh.) *Cruralis.* A muscle of the leg, situated on the fore-part of the thigh. It arises, fleshy, from between the two trochanters of the os femoris, but nearer the lesser, firmly adhering to most of the fore part of the os femoris; and is inserted, tendinous, into the upper part of the patella, behind the rectus. Its use is to assist the vasti and rectus muscles in the extension of the leg.

CRURAL. Belonging to the crus, leg, or lower extremity.

CRURAL HERNIA. Femoral hernia.

A tumour under the groin, and in the upper part of the thigh, arising from a protrusion of part of an abdominal viscus under Poupart's ligament. See *Hernia cruralis*.

Crura′lis. See *Cruræus*.

Cru′sta. A shell; a scab; the scum or surface of a fluid.

CRU′STA LA′CTEA. A disease that mostly attacks some part of the face of infants at the breast. It is known by an eruption of broad pustules, full of a glutinous liquor, which form white scabs when they are ruptured. It is cured by mineral alteratives.

Cru′sta villo′sa. The inner coat of the stomach and intestines has been so called.

Cru′stula. (Dim. of *crusta*, a shell.) An ecchymosis, or discoloration of the flesh from a bruise, where the skin is entire, and covers it over like a shell.

Crustumina′tum. (From *Crustuminum*, a town where they grew.)

1. A kind of Catherine pear.

2. A rob or electuary made of this pear and apples boiled up with honey.

Crymo′des. (From *κρυος*, cold.) An epithet for a fever, wherein the external parts are cold.

Crypso′rchis. (From *κρυπτω*, to conceal, and *ορχις*, a testicle.) When the testicles are hid in the belly, or have not descended into the scrotum.

CRY′PTÆ. (From *κρυπτω*, to hide.) The little rounded appearances at the end of the small arteries of the cortical substance of the kidneys, that appear as if formed by the artery being convoluted upon itself.

Cryptopy′ica ischu′ria. A suppression of urine from a retraction of the penis within the body.

Cryso′rchis. (Κρυσορχις.) A retraction or retrocession of one of the testicles, the same as crypsorchis.

Crysta′lli. Eruptions about the size of a lupine, white and transparent, which sometimes break out all over the body. They are also called *Crystallinæ*, and by the Italians Taroli. They are probably the pemphigus of modern writers.

CRYSTALLINE LENS. (*Lens crystallina*—*crystallina*, from its crystal-like appearance.) A lentiform pellucid part of the eye, enclosed in a membranous capsule, called the capsule of the crystalline lens, and situated in a peculiar depression in the anterior part of the vitreous humour. Its use is to transmit and refract the rays of light.

Crystalli′num. (From *κρυϛαλλος*, a crystal: so called from its transparency.) White arsenic.

CRYSTALLIZATION. (From *crystallus*, a crystal.) *Crystallizatio*. A property by which crystallizable bodies tend to assume a regular form, when placed in circumstances favourable to that particular disposition of their particles. Almost all minerals possess this property, but it is most eminent in saline substances. The circumstances which are favourable to the crystallization of salts, and without which it cannot take place, are two: 1. Their particles must be divided and separated by a fluid, in order that the corresponding faces of those particles may meet and unite. 2. In order that this union may take place, the fluid which separates the integrant parts of the salt must be gradually carried off, so that it may no longer divide them.

Crysta′llus. (From *κρυος*, cold, and *ϛελλω*, to contract: *i. e.* contracted by cold into ice.) Crystal. The antients supposed that crystals were water intensely frozen. It also means an eruption over the body of white transparent pustules. See *Crystalli*.

Cte′dones. (From *κληδων*, a rake.) The fibres are so called from their pectinated course.

Cteis. (Κτεις.) A comb or rake. *Ctenes*, in the plural number, implies those teeth which are called incisores, from their likeness to a rake.

Cube′bæ. (From *cubabah*; Arab.) See *Piper Cubeba*.

Cubebs. See *Piper Cubeba*.

CUBITAL ARTERY. *Arteria cubitalis*. *Arteria ulnaris*. A branch of the brachial that proceeds in the fore-arm, and gives off the recurrent and inter-osseals, and forms the palmary arch, from which arise branches going to the fingers, called digitals.

Cubital nerve. *Nervus cubitalis*. *Nervus ulnaris*. It arises from the brachial plexus, and proceeds along the ulna.

Cubita′lis mu′sculus. An extensor muscle of the fingers.

Cubitæ′us exte′rnus. An extensor muscle of the fingers.

Cubitæ′us inte′rnus. A flexor muscle of the fingers.

Cu′biti profu′nda ve′na. A vein of the arm.

CU′BITUS. (From *cubo*, to lie down; because the antients used to lie down on that part at their meals.) The fore-arm, or that part between the elbow and wrist.

CUBOI′DES OS. (From *κυβος*, a cube or die, and *ειδος*, likeness.) A tarsal bone of the foot, so called from its resemblance.

Cuckow flower. See *Cardamine*.

Cucu′balus be′hen. *Behen officinarum*. The spatling poppy:—*Cucubalus behen* of Linnæus, formerly used as a cordial and alexipharmic.

Cuculla′ris. (*Cucullaris*, sc. *musculus*; from *cucullus*, a hood: so named, because it is shaped like a hood.) See *Trapezius*.

Cucu′llus. A hood. An odoriferous cap for the head.

Cucumber. See *Cucumis*.

Cucumber, bitter. See *Cucumis Colocynthis*.

Cucumber, squirting. See *Momordica Elaterium.*

Cucumber, wild. See *Momordica Elaterium.*

CU′CUMIS. (*-mis,* m. also *cucumer, -ris. Quasi curvimeres,* from their curvature.) The cucumber.

1. The name of a genus of plants in the Linnæan system. Class, *Monoecia.* Order, *Syngenesia.* The cucumber.

2. The pharmacopœial name of the garden cucumber. See *Cucumis sativus.*

Cu′cumis agre′stis. See *Momordica Elaterium.*

Cu′cumis asini′nus. See *Momordica Elaterium.*

Cu′cumis colocy′nthis. The systematic name for the officinal bitter apple. *Colocynthis. Alhandula* of the Arabians. Coloquintida. Bitter apple. Bitter gourd. Bitter cucumber. The fruit which is the medicinal part of the *Cucumis colocynthis; foliis multifidis, pomis globosis glabris,* is imported from Turkey. Its spongy membranous medulla, or pith, is directed for use; it has a nauseous, acrid, and intensely bitter taste; and is a powerful irritating cathartic. In doses of ten or twelve grains, it operates with great vehemence, frequently producing violent gripes, bloody stools, and disordering the whole system. It is recommended in various complaints, as worms, mania, dropsy, epilepsy, &c.; but is seldom resorted to, except where other more mild remedies have been used without success, and then only in the form of the *extractum colocynthidis compositum* and the *pilulæ ex colocynthide cum aloë* of the pharmacopœias.

Cu′cumis me′lo. The systematic name of the melon plant. *Melo.* Musk melon. *Cucumis melo* of Linnæus. This fruit, when ripe, has a delicious refrigerating taste, but must be eaten moderately, with pepper, or some aromatic, as all this class of fruits are obnoxious to the stomach, producing spasms and colic. The seeds possess mucilaginous qualities.

Cu′cumis sati′vus. The systematic name of the cucumber plant. *Cucumis. Cucumis sativus; foliorum angulis rectis; pomis oblongis scabris,* of Linnæus. It is cooling and aperient but very apt to disagree with bilious stomachs. It should always be eaten with pepper and oil. The seeds were formerly used medicinally.

Cu′cumis sylve′stris. See *Momordica elaterium.*

Cu′cupha. A hood. An odoriferous cap for the head composed of aromatic drugs.

CUCU′RBITA. (*A curvitate,* according to Scaliger; the first syllable being doubled, as in *cacula, populus,* &c.)

1. The name of a genus of plants in the Linnæan system. Class, *Monoecia.* Order, *Syngenesia.* The pumpion.

2. The pharmacopœial name of the common pumpion or gourd.

3. A chemical distilling vessel shaped like a gourd.

Cucu′rbita citru′llus. The systematic name of the water-melon plant. *Citrullus. Angura. Jace brasiliensibus. Tetranguria.* Sicilian citrul, or water-melon. The seeds of this plant, *Cucurbita citrullus; foliis multipartitis,* of Linnæus, were formerly used medicinally, but now only to reproduce the plant. Water-melon is cooling and somewhat nutritious; but so soon begins to ferment, as to prove highly noxious to some stomachs, and bring on spasms, diarrhœas, cholera, colics, &c.

Cucu′rbita lagena′ria. The systematic name of the bottle-gourd plant. See *Cucurbita pepo.*

Cucu′rbita pe′po. The systematic name of the common pumpion. *Cucurbita.* The seeds of this plant, *Cucurbita pepo; foliis lobatis, pomis lævibus,* are used indifferently with those of the *Cucurbita lagenaria; foliis subangulatis, tomentosis, basi subtus biglandulosis; pomis lignosis.* They contain a large proportion of oil, which may be made into emulsions; but is superseded by that of sweet almonds.

Cucurbi′tinus. A species of worm, so called from its resemblance to the seed of the gourd. See *Tænia.*

CUCURBI′TULA. (A diminutive of *cucurbita,* a gourd; so called from its shape.) A cupping-glass.

CUCURBI′TULA CRUE′NTA. A cupping-glass with scarification to procure blood.

CUCURBI′TULA CUM FE′RRO. A cupping-glass with scarification to draw out blood.

CUCURBI′TULA SI′CCA. A cupping-glass without scarification.

Cue′ma. (From κυω, to carry in the womb.) The conception, or rather, as Hippocrates signifies by this word, the complete rudiments of the fœtus.

Culbi′cio. A sort of strangury, or rather heat of urine.

Culila′wan co′rtex. See *Laurus.*

CU′LINARY. (*Culinarius,* from *culina,* a kitchen.) Any thing belonging to the kitchen, as culinary salt, culinary herbs.

CULLEN, William, was born at Lanerk, Scotland, in 1712, of respectable, but not wealthy parents. After the usual school education, he was apprenticed to a surgeon and apothecary at Glasgow, and then made several voyages as surgeon to the West Indies. He afterwards settled in practice at Hamilton, and formed a connection with the celebrated William Hunter; and their business being scanty, they agreed alternately to pass a winter at some university. Cullen went first to Edinburgh, and attended the classes so diligently, that he was soon after able to commence teacher. Hunter came the next winter to London, and engaged as assistant in the dissecting room to Dr. William Douglas, who was so pleased with his assiduity and talent, as to offer him a share in his lectures: but though the partnership with Cullen was thus dissolved, they continued ever after a friendly correspondence. Cullen had the good fortune, while at Hamilton, to assist the Duke of Argyle in some chemical pursuits: and still more of being sent for to the Duke of Hamilton in a sudden alarming illness, which he speedily relieved by his judicious treatment, and gained the entire approbation of Dr. Clarke, who afterwards arrived. About the same time he married the daughter of a neighbouring clergyman, who bore him several children. In 1746 he took the degree of doctor in medicine, and was appointed teacher of chemistry at Glasgow. His talents were peculiarly fitted for this office; his systematic genius, distinct enunciation, lively manner, and extensive knowledge of the subject, rendered his lectures highly interesting. In the mean time his reputation as a physician increased, so that he was consulted in most difficult cases. In 1751 he was chosen professor in medicine to the university; and five years after the chemical chair at Edinburgh was offered him, on the death of Dr. Plummer, which was too advantageous to be refused. He soon became equally popular there, and his class increased, so as to exceed that of any other professor, except the anatomical. This success was owing not only to his assiduity, and his being so well qualified for the office, but also in a great measure to the kindness which he showed to his pupils, and partly to the new Views on the Theory of Medicine, which he occasionally introduced into his lectures. He appears also about this time to have given Clinical Lectures at the Infirmary. On the death of Dr. Alston, Lecturer on the Materia Medica, he was appointed to succeed him: and six years after, jointly with Dr. Gregory, to lecture on the Theory and Practice of Medicine, when he resigned the Chemical Chair to his pupil, Dr. Black. Dr. Gregory having died the following year, he continued the Medical Lectures alone, till within a few months of his death, which happened in February 1790, in his seventy-seventh year; and he is said, even at the last, to have shown no deficiency in his delivery, nor in his memory, being accustomed to lecture from short notes. His Lectures on the Materia Medica being surreptitiously printed, he obtained an injunction against their being issued, until he had corrected them; which was accomplished in 1772: but they were afterwards much improved, and appeared in 1789, in two quarto volumes. Fearing a similar fate to his Lectures on Medicine, he published an outline of them in 1784, in four volumes, octavo, entitled "First Lines of the Practice of Physic." He wrote also the "Institutions of Medicine," in one volume, octavo: and a Letter to Lord Cathcart, on the Recovery of drowned Persons. But his most celebrated work is his Synopsis Nosologiæ Methodicæ, successively improved in different editions; the fourth, published in 1785, in two octavo volumes, contains the Systems of other Nosologists till that period, followed by his own, which certainly, as a practical arrangement of diseases, greatly surpasses them.

CULPEPER, Nicholas, was the son of a clergyman, who put him apprentice to an apothecary; after serving his time, he settled in Spitalfields, London, about the year 1642. In the troubles prevailing at that period he appears to have favoured the Puritans: but his decided warfare was with the College of Physicians, whom he accuses of keeping the people in ignorance, like the Popish clergy. He, therefore, published a translation of their Dispensary with practical remarks; also a Herbal, pointing out among other matters under what planet the plants should be gathered; and a directory to midwives, showing the method of insuring a healthy progeny, &c. These works were for some time popular. He died in 1654.

CU'LTER. (From *colo*, to cultivate.) A knife or shear. The third lobe of the liver is so called from its resemblance.

Cu'lus. (From κουλος.) The anus or fundament.

Cu'mamus. See *Piper cubeba*.

Cumin seeds. See *Cuminum*.

CU'MINUM. (From κυω, to bring forth; because it was said to cure sterility.) *Cyminum. Fœniculum orientale*.

1. The name of a genus of plants in the Linnæan system. Class, *Heptandria*. Order, *Digynia*. The cumin plant.

2. The pharmacopœial name of the *Cuminum cyminum* of Linnæus.

Cu'minum æthio'picum. A name for the ammi verum.

Cu'minum cy'minum. The systematic name of the cumin plant. *Cuminum*. A native of Egypt and Ethiopia, but cultivated in Sicily and Malta, from whence it is brought to us. The seeds of cumin, which are the only part of the plant in use, have a bitterish taste, accompanied with an aromatic flavour, but not agreeable. They are generally preferred to other seeds for external use in discussing indolent tumours, as the encysted scrophulous, &c. and give name both to a plaster and cataplasm in the pharmacopœias.

Cunea'lis sutu'ra. The suture by which the os sphenoides is joined to the os frontis.

CU'NEIFORM. (*Cuneiformis*; from *cuneus*, a wedge, and *forma*, likeness.) Some parts of the body are so called, being shaped, or fixed in, like a wedge: such are the sphenoid bone, and some bones of the wrist and tarsus.

Cune′olus. (From *cuneo*, to wedge.) A crooked tent to put into a fistula.

CUPEL. (*Kuppel*, German.) *Copella. Catellus cinereus. Cineritium. Patella docimastica. Testa probatrix, exploratrix*, or *docimastica.* A chemical instrument, which suffers the baser metals to pass through it, when exposed to heat, and retains the pure metal. This process is termed cupellation.

CUPELLA′TION. (From *kuppel*, German.) The purifying of perfect metals by means of an addition of lead, which at a due heat becomes vitrified, and promotes the vitrification and calcination of such imperfect metals as may be in the mixture, so that these last are carried off in the fusible glass that is formed, and the perfect metals are left nearly pure. The name of this operation is taken from the vessels made use of, which are called cupels.

Cu′phos. (Κουφος.) Light, when applied to aliments, it imports their being easily digested; when to distempers, that they are mild.

CUPRE′SSUS. (So called, *απο του κυειν παρισους τους ακρεμονας*, because it produces equal branches.) Cypress.

1. The name of a genus of plants in the Linnæan system. Class, *Monœcia.* Order, *Monadelphia.* The cypress-tree.

2. The pharmacopœial name of the *Cupressus sempervirens* of Linnæus.

Cupre′ssus sempe′rvirens. The systematic name of the cupressus of the shops. *Cupressus foliis imbricatis squamis quadrangulis*, of Linnæus; called also *cyparissus.* Every part of the plant abounds with a bitter, aromatic, terebinthinate fluid; and is said to be a remedy against intermittents. Its wood is extremely durable, and constitutes the cases of Egyptian mummies.

Cu′pri ammonia′ti li′quor. Solution of ammoniated copper. *Aqua cupri ammoniati* of Pharm. Lond. 1787, and formerly called *aqua sapphirina.* "Take of ammoniated copper, a drachm; distilled water, a pint." Dissolve the ammoniated copper in the water, and filter the solution through paper. This preparation is employed by surgeons for cleansing foul ulcers, and disposing them to heal.

Cu′pri rubi′go. Verdigris.

CU′PRI SU′LPHAS. *Vitriolum cupri. Vitriolum cæruleum. Vitriolum Romanum. Cuprum vitriolatum.* The sulphate of copper possesses acrid and styptic qualities; is esteemed as a tonic, emetic, adstringent, and escharotic, and is exhibited internally in the cure of dropsies, hæmorrhages, and as a speedy emetic. Externally it is applied to stop hæmorrhages, to hæmorrhoids, leucorrhœa, phagedænic ulcers, proud flesh, and condylomata.

CU′PRUM. (*Quasi æs Cyprium:* so called from the island of Cyprus, whence it was formerly brought.) See *Copper.*

Cu′prum ammoniaca′le. See *Cuprum ammoniatum.*

CU′PRUM AMMONIA′TUM. *Cuprum ammoniacale.* Ammoniated copper. Ammoniacal sulphate of copper. Take of sulphate of copper, half an ounce; subcarbonate of ammonia, six drachms; rub them together in a glass mortar; till the effervescence ceases; then dry the ammoniated copper, wrapped up in bibulous paper, by a gentle heat. In this process the carbonic acid is expelled from the ammonia, which forms a triple compound with the sulphuric acid and oxide of copper. This preparation is much milder than the sulphate of copper. It is found to produce tonic and astringent effects on the human body. Its principal internal use has been in epilepsy, and other obstinate spasmodic diseases, given in doses of half a grain, gradually increased to five grains or more, two or three times a day. For its external application, see *Cupri ammoniati liquor.*

Cu′prum vitriola′tum. See *Cupri Sulphas.*

Cu′ra avena′cea. A decoction of oats and succory roots, in which a little nitre and sugar were dissolved, was formerly used in fevers, and was thus named.

Cu′rcas. The Barbadoes nut; a drastic purge.

Cu′rculio. (From *karkarah.* Heb.) The throat; the aspera arteria.

Cu′rcum. The large celandine; deobstruent.

CURCU′MA. (From the Arabic *curcum*, or *herçum.*) Turmeric.

1. The name of a genus of plants in the Linnæan system. Class, *Monandria.* Order, *Monogynia.*

2. The pharmacopœial name of the turmeric-tree. See *Curcúma longa.*

Curcu′ma lo′nga. The turmeric plant. *Curcuma; foliis lanceolatis; nervis lateralibus numerossimis* of Linnæus. *Crocus Indicus. Terra marita. Cannacorus radice croceo. Curcuma rotunda. Mayella. Kua kaha* of the Indians. The Arabians call every root of a saffron colour by the name of *curcum.* The root of this plant is imported here in its dried state from the East Indies, in various forms. Externally it is of a pale yellow colour, wrinkled, solid, ponderous, and the inner substance of a deep saffron or gold colour: its odour is somewhat fragrant; to the tasté it is bitterish, slightly acrid, exciting a moderate degree of warmth in the mouth, and on being chewed it tinges the saliva yellow. It is an ingredient in the composition of *Curry powder*, is valuable as a dyeing drug, and furnishes a chemical test of the presence of uncombined alkalies. It is now very seldom used medicinally, but retains a place in our pharmacopœias.

Curcu'ma ro'tunda. See *Curcuma longa.*

CU'RMI. (From κεραω, to mix.) Ale. A drink made of barley, according to Dioscorides.

Currants. See *Ribes.*

Cu'rsuma. *Curtuma.* The *Ranunculus ficaria* of Linnæus.

Curva'tor co'ccygis. A muscle bending the coccyx.

Cursu'ta. (Corrupted from *cassuta*, *kasuth*, Arab.) The root of the *Gentiana purpurea* of Linnæus.

CUSCU'TA. (According to Linnæus, a corruption from the Greek Κασυτας, or Καδυτας, which is from the Arabic *Chessuth*, or *Chasuth.*) Dodder.

1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria.* Order, *Digynia.*

2. The pharmacopœial name of dodder of thyme. See *Cuscuta Epithymum.*

Cuscu'ta epithy'mum. The systematic name of dodder of thyme. *Epithymum. Cuscuta.* Dodder of thyme. A parasitical plant, possessing a strong disagreeable smell, and a pungent taste, very durable in the mouth. Two kinds are recommended in melancholia, as cathartics, viz. *Cuscuta epithymum; foliis sessilibus, quinquifidis, bracteis obvallatis,* and *cuscuta europæa; floribus sessilibus* of Linnæus.

Cuscu'ta Europæ'a. The systematic name of a species of dodder of thyme. See *Cuscuta Epithymum.*

CUSPIDA'TUS. (From *cuspis*, a point.) See *Teeth.*

CUSPA'RIA. The generic name given by Messrs. Humboldt and Bonpland to the tree from which we obtain the Angustura bark.

Cuspa'ria febri'fuga. This is the tree said to yield the bark called angustura. *Cortex cuspariæ.* A bark imported from Angustura in South America. Its external appearances vary considerably. The best is not fibrous, but hard, compact, and of a yellowish-brown colour, and externally of a whitish hue. When reduced into powder, it resembles that of Indian rhubarb. It is very generally employed as a febrifuge, tonic, and adstringent. While some deny its virtue in curing intermittents, by many it is preferred to the Peruvian bark; and it has been found useful in diarrhœa, dyspepsia, and scrofula. It was thought to be the bark of the *Brucea antidysenterica*, or *ferruginea.* Willdenow suspected it to be the *Magnalia plumieri;* but Humboldt and Bonpland, the celebrated travellers in South America, have ascertained it to belong to a tree not before known, and which they promise to describe by the name of *Cusparia febrifuga.*

Cu'spis. (From *cuspa*, Chald. a shell, or bone, with which spears were formerly pointed.) The glans penis was so called, from its likeness to the point of a spear. Also a bandage.

Cu'stos o'culi. An instrument to fix the eye during an operation.

Cuta'mbuli. (From *cutis*, the skin, and *ambulo*, to walk.) Cutaneous worms; scorbutic itching.

Cuta'neus mu'sculus. The platysma myoides.

CUTANEOUS. (From *cutis*, the skin.) Belonging to the skin.

CUTICLE. (*Cuticula*, dim. of *cutis*, the skin.) *Epidermis.* Scarf-skin. A thin, pellucid, insensible membrane, of a white colour, that covers and defends the true skin, with which it is connected by the hairs, exhaling and inhaling vessels, and the rete mucosum.

CU'TIS. (*-tis*, fœm.) *Derma.* The true skin. A thick, fibrous, vascular, and nervous membrane, that covers the whole external surface of the body, and is the seat of the organ of touch, as also of exhalation, and inhalation.

CU'TIS ANSERI'NA. (*Anserina;* from *anser*, a goose.) The rough state the skin is sometimes thrown into from the action of cold, or other cause, in which it looks like the skin of the goose.

CU'TIS VE'RA. The true skin under the cuticle.

Cy'anus. (Κυανος, cærulean, or sky-blue; so called from its colour.) Blue-bottle. See *Centaurea.*

Cy'ar. (From κεω, to pour out.) The lip of a vessel. The eye of a needle; and the orifice of the internal ear, from its likeness to the eye of a needle.

Cya'sma. Spots on the skin of pregnant women.

Cyathi'scus. (From κυαθος, a cup.) The hollow part of a probe, formed in the shape of a small spoon, as an ear-picker.

Cy'bitos. See *Cubitus.*

Cy'bitum. See *Cubitus.*

Cy'bitus. See *Cubitus.*

Cyboi'des. See *Cuboides.*

Cy'ceum. (From κυκαω, to mix.) *Cyceon.* A mixture of the consistence of pap.

Cy'cima. (From κυκαω, to mix.) So called from the mixture of the ore with lead, by which litharge is made.

CY'CLAMEN. (From κυκλος, circular; either on account of the round form of the leaves, or of the roots.) Cyclamen.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

2. The pharmacopœial name of the sow-bread.

Cy'clamen Europæ'um. The systematic name of the *Arthanita*, or sow-bread.

Cycli'scus. (From κυκλος, a circle.) An

instrument in the form of a half moon, formerly used for scraping rotten bones.

Cycli′smus. (From κυκλος, a circle.) A lozenge.

Cyclopho′ria. (From κυκλος, a circle, and φερω, to bear.) The circulation of the blood, or other fluids.

Cyclo′pion. (From κυκλοω, to surround, and ωψ, the eye.) The white of the eye.

Cy′clos. A circle. Hippocrates uses this word to signify the cheeks, and the orbits of the eyes.

Cy′clus metasyncri′ticus. It is a long protracted course of remedies, persisted in with a view of restoring the particles of the body to such a state as is necessary to health.

CYDO′NIUM MA′LUM. (From *Cydon*, a town in Crete, where they grew.) The quince. See *Pyrus Cydonia.*

Cye′ma. (From κυω, to bring forth.) Parturition.

Cyli′chnis. (From κυλιξ, a cup.) A gallipot or vessel of any kind to hold medicines in.

Cyllo′sis. (From κυλλοω, to make lame.) A tibia or leg bending outwards.

Cyli′ndrus. (From κυλιω, to roll round.) A cylinder. A tent for a wound, equal at the top and bottom.

Cy′lus. (From κυλλοω, to make lame.) In Hippocrates, it is one affected with a kind of luxation, which bends outwards, and is hollowed inward. Such a defect in the tibia is called *Cyllosis*, and the person to whom it belongs, is called by the Latins *Varus*, which term is opposed to *Valgus.*

Cymato′des. Is applied by Galen and some others to an unequal fluctuating pulse.

Cy′mba. (From κυμβος, hollow.) A boat, or pinnace. A bone of the wrist is so called, from its supposed likeness to a skiff.

Cymina′lis. Gentian.

Cy′minum. See *Cuminum.*

CYNA′NCHE. (From κυων, a dog, and αγχω, to suffocate, or strangle; so called from dogs being said to be subject to it.) Sore throat. A genus of disease in the class *pyrexiæ*, and order *phlegmasiæ* of Cullen. It is known by pain and redness of the throat, attended with a difficulty of swallowing and breathing. The species of this disease are:—

1. *Cynanche trachealis;* called also by some *cynanche laryngea. Suffocatio stridula angina perniciosa. Asthma infantum. Cynanche stridula. Morbus strangulatorius. Catarrhus suffocatious Barbadensis. Angina polyposa sive membranacea.* The croup. A disease that mostly attacks infants, who are suddenly seized with a difficulty of breathing and a crouping noise: it is an inflammation of the mucous membrane of the trachea that induces the secretion of a very tenacious coagulable lymph, which lines the trachea and bronchia, and impedes respiration. The croup does not appear to be contagious, whatever some physicians may think to the contrary; but it sometimes prevails epidemically. It seems, however, peculiar to some families; and a child having once been attacked, is very liable to its returns. It is likewise peculiar to young children, and has never been known to attack a person arrived at the age of puberty.

The application of cold seems to be the general cause which produces this disorder, and therefore it occurs more frequently in the winter and spring, than in the other seasons. It has been said, that it is most prevalent near the sea-coast; but it is frequently met with in inland situations, and particularly those which are marshy.

Some days previous to an attack of the disease, the child appears drowsy, inactive, and fretful; the eyes are somewhat suffused and heavy; and there is a cough, which, from the first, has a peculiar shrill sound; this, in the course of two days, becomes more violent and troublesome, and likewise more shrill. Every fit of coughing agitates the patient very much; the face is flushed and swelled, the eyes are protuberant, a general tremor takes place, and there is a kind of convulsive endeavour to renew respiration at the close of each fit. As the disease advances, a constant difficulty of breathing prevails, accompanied sometimes with a swelling and inflammation in the tonsils, uvula, and velum pendulum palati; and the head is thrown back, in the agony of attempting to escape suffocation. There is not only an unusual sound produced by the cough, (something between the yelping and barking of a dog,) but respiration is performed with a hissing noise, as if the trachea was closed up by some slight spongy substance. The cough is generally dry; but if any thing is spit up, it has either a purulent appearance, or seems to consist of films resembling portions of a membrane. Where great nausea and frequent retchings prevail, coagulated matter of the same nature is brought up. With these symptoms, there is much thirst, and uneasy sense of heat over the whole body, a continual inclination to change from place to place, great restlessness, and frequency of the pulse.

In an advanced stage of the disease, respiration becomes more stridulous, and is performed with still greater difficulty, being repeated at longer periods, and with greater exertions, until at last it ceases entirely.

The croup generally proves fatal by suffocation, induced either by spasm affecting the glottis, or by a quantity of matter blocking up the trachea or bronchia; but when it terminates in health, it is by a resolution of the inflammation, by a ceasing of the spasms, and by a free expectoration of the matter exuding from the trachea, or of the crusts formed there.

The disease has, in a few instances, terminated fatally within twenty-four hours after its attack: but it more usually happens, that where it proves fatal, it runs on to the fourth or fifth day. Where considerable portions of the membranous films, formed on the surface of the trachea, are thrown up, life is sometimes protracted for a day or two longer than would otherwise have happened.

Dissections of children who have died of the croup, have always shown a preternatural membrane, lining the whole internal surface of the upper part of the trachea, which may always be easily separated from the proper membrane. There is likewise usually found a good deal of mucus, with a mixture of pus, in the trachea and its ramifications.

The treatment of this disease must be conducted on the strictly antiphlogistic plan. It will commonly be proper, where the patient is not very young, to begin by taking blood from the arm, or the jugular vein; several leeches should be applied along the fore part of the neck: it will then be right to give a nauseating emetic, ipecacuanha with tartarized antimony, or with squill in divided doses; this may be followed up by cathartics, diaphoretics, digitalis, &c.: large blisters ought to be applied near the affected part, and a discharge kept up by savine cerate, or other stimulant dressing. Mercury, carried speedily to salivation, has in several instances arrested the progress of the disease, when it appeared proceeding to a fatal termination. As the inflammation is declining, it is very important that free expectoration should take place; this may be promoted by nauseating medicines, by inhaling steam, and by stimulating gargles; for which the decoction of seneka is particularly recommended. Where there is much wheezing, an occasional emetic may relieve the patient considerably: and under symptoms of threatening suffocation, the operation of bronchotomy has sometimes saved life. Should fits of spasmodic difficulty of breathing occur in the latter periods of the disease, opium joined with diaphoretics would be most likely to do good.

2. *Cynanche tonsillaris.* The inflammatory quincy, called also *angina inflammatoria.* In this complaint, the inflammation principally occupies the tonsils; but often extends through the whole mucous membrane of the fauces, so as essentially to interrupt the speech, respiration, and deglutition of the patient.

The causes which usually give rise to it are, exposure to cold, either from sudden vicissitudes of weather, from being placed in a partial current of air, wearing damp linen, sitting in wet rooms, or getting wet in the feet; all of which may give a sudden check to perspiration. It principally attacks those of a full and plethoric habit, and is chiefly confined to cold climates, occurring usually in the spring and autumn; whereas the ulcerated sore throat chiefly attacks those of a weak irritable habit, and is most prevalent in warm climates. The former differs from the latter likewise in not being contagious. In many people there seems to be a particular tendency to this disease; as from every considerable application of cold it is readily induced.

An inflammatory sore throat discovers itself by a difficulty of swallowing and breathing, accompanied by a redness and tumour in one or both tonsils, dryness of the throat, foulness of the tongue, lancinating pains in the parts affected, a frequent but difficult excretion of mucus, and some small degree of fever. As the disease advances, the difficulty of swallowing and breathing becomes greater, the speech is very indistinct, the dryness of the throat and thirst increase, the tongue swells and is incrusted with a dark fur, and the pulse is full and frequent. In some cases, a few white, sloughly spots are to be observed on the tonsils. If the inflammation proceeds to such a height as to put a total stop to respiration, the face will become livid, the pulse will sink, and the patient will quickly be destroyed.

The chief danger arising from this species of quincy is, the inflammation occupying both tonsils, and proceeding to such a degree as to prevent a sufficient quantity of nourishment for the support of nature from being taken, or to occasion suffocation; but this seldom happens, and its usual termination is either in resolution or suppuration. When proper steps are adopted, it will in general readily go off by the former.

Where the disease has proved fatal by suffocation, little more than a highly inflamed state of the parts affected, with some morbid phenomena in the head, have been observed on dissection.

This is usually a complaint not requiring very active treatment. If, however, the inflammation run high, in a tolerably strong and plethoric adult, a moderate quantity of blood should be drawn from the arm, or the jugular vein: but still more frequently leeches will be required; or scarifying the tonsils may afford more effectual relief. An emetic will often be very beneficial, sometimes apparently check the progress of the complaint: likewise cathartics must be employed, diaphoretics, and the general antiphlogistic regimen. A blister to the throat, or behind the neck, sometimes has a very excellent effect: but in milder cases, the linimentum ammoniæ, or other rubefacient application, applied every six or eight hours, and wearing flannel round the throat, may produce a sufficient determination from the part affected. The use of proper gargles generally contributes materially to the cure: if there be much tension and pain in the fauces, a solution of nitrate of potash will be best; otherwise dilute acids, a weak solution of alum, &c. Should the disease proceed to suppuration, warm emollient gargles ought to be employed, and perhaps similar external applications may be of some service: but it is particularly important to make an early opening into the abscess for the discharge of the pus. When deglutition is prevented by the tumefaction of the tonsils, it is recommended to exhibit nutritious clysters; and when suffocation is threatened, an emetic, or inhaling ether, may cause a rupture of the abscess, or this may be opened; but if relief be not thereby obtained bronchotomy will become necessary.

3. *Cynanche pharyngea.* This species is so called when the pharynx is chiefly affected. Dr. Wilson, in his Treatise on Febrile Diseases, includes in his definition of cynanche tonsillaris, that of cynanche pharyngea. These varieties of cynanche differ considerably when they are exquisitely formed. But the one is seldom present in any considerable degree without being attended with more or less of the other. Dr. Cullen declares, indeed, that he never saw a case of true cynanche pharyngea; that is, a case in which the inflammation was confined to the pharynx; it constantly spread in a greater or less degree to the tonsils and neighbouring parts. Besides the mode of treatment is, in almost every instance, the same in both cases. And if we admit the cynanche pharyngea to be a distinct variety, we must admit another, the cynanche œsophagea; for inflammation frequently attacks the œsophagus, and is sometimes even confined to it.

4. *Cynanche parotidea.* The mumps. A swelling on the cheek and under the jaw, extending over the neck, from inflammation of the parotid and other salivary glands, rendering deglutition, or even respiration, sometimes difficult, declining the fourth day. Epidemic and contagious.

The disease is subject to a metastasis occasionally, in females to the mammæ, in males to the testes; and in a few instances repelled from these parts it has affected the brain and even proved fatal. In general, however, the disease is without danger, and scarcely calls for medical aid. Keeping a flannel over the part, and the antiphlogistic regimen, with mild laxatives, will be sufficient. Should the mammæ, or the testes, be affected, more active evacuations may be necessary to prevent the destruction of those organs, bleeding general and topical, &c. but avoiding cold applications, lest it should be driven to the brain. And where this part is unfortunately attacked, besides the means explained under *Phrenitis,* it may be useful to endeavour to recall the inflammation to its former seat by warm fomentations, stimulant liniments, &c.

5. *Cynanche maligna.* The malignant, putrid, or ulcerous sore throat. Called also *cynanche gangrænosa. Angina ulcerosa. Febris epidemica cum angina ulcusculosa. Angina epidemica. Angina gangrænosa. Angina suffocativa. Angina maligna.* This disease is readily to be distinguished from the inflammatory quincy, by the soreness and specks which appear in the fauces, together with the great debility of the system, and small fluttering pulse, which are not to be observed in the former. In the inflammatory sore throat there is always great difficulty of swallowing, a considerable degree of tumour, with a tendency in the parts affected to suppurate, and a hard, full pulse. Moreover in the former affection the disease is seated principally in the mucous membrane of the mouth and throat; whereas in the latter the inflammation chiefly occupies the glandular parts.

The putrid sore throat often arises from a peculiar state of the atmosphere, and so becomes epidemical; making its attacks chiefly on children, and those of a weak relaxed habit. It is produced likewise by contagion, as it is found to run through a whole family, when it has once seized any person in it; and it proves often fatal, particularly to those in an infantile state.

It appears, however, that under this head two different complaints have been included; the one, especially fatal to children, is an aggravated form of scarlatina; the other, a combination of inflammation of the fauces with typhus fever: the former is perhaps always, the latter certainly often, contagious. See *Scarlatina* and *Typhus.*

CYNA'NCHE A DEGLUTI'TIS. Quincy from hard substances swallowed.

CYNA'NCHE A DYSENTE'RIA. Quincy from dysentery.

CYNA'NCHE ANGINO'SA. The inflammatory quincy.

CYNA'NCHE ARTHRI'TICA. Quincy from gout.

CYNA'NCHE EPIDE'MICA. The cynanche maligna.

CYNA'NCHE GANGRÆNO'SA. The cynanche maligna.

CYNA'NCHE HEPA'TICA. Quincy from a disease of the liver.

CYNA'NCHE LARYNGE'A. The cynanche trachealis.

CYNA'NCHE MALI'GNA. See *Cynanche.*

CYNA'NCHE PAROTIDE'A. See *Cynanche.*

CYNA'NCHE PHARYNGE'A. See *Cynanche.*

CYNA'NCHE PRUNE'LLA. Common sore throat.

CYNA'NCHE PURPURO-PAROTIDE'A. A cynanche maligna, or malignant sore throat.

CYNA'NCHE STRI'DULA. The croup. See *Cynanche.*

CYNA'NCHE THY'MICA. Sore throat from an enlargement of the thyroid gland.

CYNA'NCHE TONSILLA'RIS. See *Cynanche.*

CYNA'NCHE TRACHEA'LIS. See *Cynanche.*

Cyna'nche ulcero'sa. The malignant sore throat.

Cyna'nchica. (From κυναγχη, the quincy.) Medicines which relieve a quincy.

Cynanthro'pia. (From κυων, a dog, and ανθρωπος, a man.) It is used by Bellini, De Morbis Capitis, to express a particular kind of melancholy, when men fancy themselves changed into dogs, and imitate their actions.

Cy'nara sco'lymus. See *Cinara.*

Cy'nchnis. (Κυγχνις.) A vessel of any kind to hold medicines in.

Cynocra'mbe. (From κυων, a dog, and κραμϐη, cabbage; a herb of the cabbage tribe, with which dogs are said to physic themselves.) See *Mercurialis perennis.*

Cyno'ctanum. (From κυων, a dog, and κτεινω, to kill.) A species of aconitum, said to destroy dogs if they eat it.

Cynocy'tisis. (From κυων, a dog, and κυτισος, the cytisus; so named because it was said to cure the distemper of dogs.) The dog-rose. See *Rosa canina.*

Cynode'ctos. (From κυων, a dog, and δακνω, to bite.) So Dioscorides calls a person bit by a mad dog.

Cynode'smion. (From κυων, a dog, and δεω, to bind; so named because in dogs it is very discernible and strong.) A ligature by which the prepuce is bound upon the glans. Sometimes it signifies the lower part of the prepuce.

Cynodo'ntes. (Κυνοδοντες: from κυων, a dog, and οδους, a tooth.) The canine teeth.

CYNOGLO'SSUM. (From κυων, a dog, and γλωσσα, a tongue; so named from its supposed resemblance.) Hound's tongue.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.*

2. The pharmacopœial name of the cynoglossum officinale.

Cynoglo'ssum officina'le. The systematic name for hound's tongue. *Cynoglossum. Lingua canina. Cynoglossum staminibus corolla brevioribus; foliis lato lanceolatis, tomentosis, sessilibus,* of Linnæus. It possesses narcotic powers, but is seldom employed medicinally. Acids are said to counteract the ill effects from an overdose more speedily than any thing else, after clearing the stomach.

Cyno'lophus. (From κυων, a dog, and λοφος, a protuberance; so called because in dogs they are peculiarly eminent.) The asperities and prominences of the vertebræ.

Cynoly'ssa. (From κυων, a dog, and λυσση, madness.) Canine madness.

CYNOMO'RIUM. The name of a genus of plants in the Linnæan system. Class, *Monœcia.* Order, *Monandria.*

Cynomo'rium cocci'neum. The systematic name of the *fungus melitensis. Fungus melitensis.* This is improperly called a fungus, it being the *Cynomorium coccineum* of Linnæus, a small plant which grows only on a little rock adjoining Malta. A drachm of the powder is given for a dose in dysenteries and hæmorrhages, and with remarkable success.

Cynore'xia. (From κυων, a dog, and ορεξις, appetite.) A voracious or canine appetite. See *Bulimia.*

Cyno'sbatos. See *Cynosbatus.*

CYNO'SBATUS. (From κυων, a dog, and βατος, a thorn; so called because dogs are said to be attracted by its smell.) The dog-rose. See *Rosa canina.*

Cynospa'stum. (From κυων, a dog, and σπαω, to attract.) See *Rosa canina.*

Cyopho'ria. (From κυος, a fœtus, and φερω, to bear.) *Gestation.* The pregnancy of a woman.

Cypari'ssus. See *Cupressus.*

CY'PERUS. (From κυπαρος, a little round vessel, which its roots are said to resemble.) Cyperus. The name of a genus of plants in the Linnæan system. Class, *Triandria.* Order, *Monogynia.*

Cy'perus lo'ngus. The pharmacopœial name of the English galangale. *Cyperus longus; culmo triquetro folioso, umbella foliosa supra-decomposita; pedunculis nudis, spicis alternis,* of Linnæus. The smell of the root of this plant is aromatic, and its taste warm, and sometimes bitter. It is now totally fallen into disuse.

Cy'perus rotu'ndus. This species, the round cyperus, *Cyperus rotundus; culmo triquetro subnudo, umbella decomposita; spicis alternis linearibus,* of Linnæus, is generally preferred to the former, being a more gratefully aromatic bitter. It is chiefly used as a stomachic.

Cypho'ma. (From κυπτω, to bend.) A gibbosity, or curvature of the spine.

Cypho'sis. An incurvation of the spine.

Cypress spurge. See *Esula minor.*

Cy'prinum o'leum. Flowers of cypress, calamus, cardamoms, &c. boiled in olive oil.

Cy'prium. (From Κυπρος, Cyprus, an island where it is said formerly to have abounded.) Copper.

CYPRUS. The cypress-tree, or Eastern privet; so called from the island of Cyprus, where it grew abundantly.

Cy'pselis. (From κυψελη, a bee-hive.) The aperture of the ear; the ear-wax.

Cyrcne'sis. (From κυρκναω, to mix.) A mixture, or composition.

Cyrto'ma. (From κυρτος, curved.) An unnatural convex tumour; tympanites.

Cyrtono'sus. (From κυρτος, curved, and νοσος, a disease.) The rickets, or curved spine.

Cy'ssarus. (From κυσος, the anus.) The intestinum rectum is so called, because it reaches to the anus.

Cysso'tis. (From κυσος, the anus.) An inflammation of the anus.

Cysteoli'thus. (From κυστις, the bladder, and λιθος, a stone.) The stone in the bladder.

Cy'sthus. (Κυσθος.) The anus.

CYSTIC. Belonging to the urinary or gall bladder.

Cystic duct. *Ductus cysticus.* The membranous canal that conveys the bile from the hepatic duct into the gall-bladder.

Cy'stica. (From κυστις, the bladder.) Remedies for diseases of the bladder.

Cy'stides. (From κυστις, a bag.) Encysted tumours.

Cystiphlo'gia. (From κυστις, the bladder, and φλεγω, to burn.) An inflammation in the bladder.

Cystirrha'gia. (From κυστις, the bladder, and ρηγνυμι, to burst forth.) A discharge of blood from the bladder.

CY'STIS. (Κυστις, a bag.) The bladder; any receptacle of morbid humours. See *Urinary bladder.*

CY'STIS CHOLE'DOCHA. See *Gall-bladder.*

CY'STIS FE'LLEA. See *Gall-bladder.*

CYSTI'TIS. (From κυστις, the bladder.) Inflammation of the bladder. A genus of disease arranged by Cullen in the class *pyrexiæ*, and order *phlegmasiæ.* It is known by great pain in the region of the bladder, attended with fever and hard pulse, a frequent and painful discharge of urine, or a suppression, and generally tenesmus. This is rarely a primary disease, and when it occurs, the above character of it will readily point it out. There is frequently also nausea and vomiting, and, in some cases, delirium. It most generally arises in consequence of inflammation of the adjacent parts, or from calculi in the bladder. The treatment is very similar to that of *Nephritis;* which see. When suppression of urine attends, the catheter must be occasionally introduced.

CYSTOCE'LE. (From κυστις, the bladder, and κηλη, a tumour.) An hernia formed by the protusion of the urinary bladder

Cystoli'thicus. (From κυστις, the bladder, and λιθος, a stone.) A suppression of urine from a stone in the bladder, is called ischuria cystolithica.

Cystophle'gicus. (From κυστις, the bladder, and φλεγω, to burn.) A suppression of urine from an inflammation of the bladder, was formerly called ischuria cystophlegica.

Cystophlegma'tica. (From κυστις, the bladder, and φλεγμα, phlegm.) A suppression of urine, from too much matter or mucus in the bladder, was called ischuria cystophlegmatica.

Cystopro'ctica. (From κυστις, the bladder, and ϖρωκτος, the anus, or rectum.) A suppression of urine, caused by wind, inflammation of the rectum, hardened fæces, &c. is called ischuria cystoproctica.

Cystopto'sis. (From κυστις, the bladder, and ϖιπτω, to fall.) A protrusion of the inner membrane of the bladder, through the urethra.

Cystospa'sticus. (From κυστις, the bladder, and σπασμα, a spasm.) A suppression of urine, from a spasm in the sphincter of the bladder, was called ischuria cystospastica.

Cystospy'icus. (From κυστις, the bladder, and ϖυον, pus.) A suppression of urine, from purulent matter in the bladder, was called ischuria cystospyica.

Cystothromboi'des. (From κυστις, the bladder, and θρομβος, a coagulation of blood.) A suppression of urine, from a concretion of grumous blood in the bladder, was called ischuria cystothromboides.

CYSTOTO'MIA. (From κυστις, the bladder, and τεμνω, to cut.) The operation of cutting or piercing the bladder.

Cy'thion. An eye-wash.

Cy'tinus. (From κυω, to produce; so called from its fecundity.) The bud or flower of the pomegranate.

Cy'tinus hypoci'stis. The plant on whose fruit the *succus hypocistidis* is obtained. See *Hypocistis.*

Cytiso-geni'sta. Common broom. See *Spartium.*

Cyzemer. A painful swelling of the wrists.

Cyzice'nus. A plaster for wounds of the nerves.

D.

D. This letter signifies vitriol in the old chemical alphabet.

Dacne'rus. (From δακνω, to bite.) Biting. Pungent. An epithet for a sharp collyrium, or eye-wash, composed of burnt copper, pepper, cadmia, myrrh, and opium.

Dacry'dium. (From δακρυ, a tear.) The inspissated juice of scammony. It is in small drops, and therefore called a tear.

Dacrygelo'sis. (From δακρυω, to weep, and γελαω, to laugh.) A species of insanity, in which the patient weeps and laughs at the same time.

Dacryo'des. (From δακρυω, to weep.) A sanious ulcer. A weeping sore.

Dacryo'ma. (From *δακρυω*, to weep.) A closing of one or more of the puncta lachrymalia, causing an effusion of tears.

Dactyle'thra. (From *δακτυλος*, a finger.) A species of bougies shaped like a finger, to excite vomiting.

Dactyle'tus. (From *δακτυλος*, the date.) The hermodactylus.

Da'ctylius. (From *δακτυλος*, a finger.) A round pastil troche, or lozenge, shaped like a finger.

Da'ctylus. (From *δακτυλος*, a finger; so called from the likeness of its fruit to a finger.) The date. See *Phœnix dactylifera.*

Dæ'dium. (From *δαις*, a torch.) A small torch or candle. A bougie.

Dæmonoma'nia. (From *δαιμων*, a dæmon, and *μανια*, madness.) That species of melancholy, where the patient supposes himself to be possessed by devils.

Daisy, common. See *Bellis perennis.*

Daisy, ox-eye. See *Chrysanthemum leucanthemum.*

DALE, Samuel, was born in 1659. After practising as an apothecary, he became a licentiate of the college of physicians, and settled at Bocking, where he continued till his death in 1739. He was also chosen a fellow of the Royal Society. In 1693 he published his "Pharmacologia," an Introduction to the Materia Medica, which he afterwards much enlarged and improved: the work was well received, and passed through many editions. He also gave a good account of the natural productions about Harwich and Dover Court.

Damask rose. See *Rosa centifolia.*

Damna'tus. (From *damno*, to condemn.) The dry useless fæces, left in a vessel after the moisture has been distilled from it, is called terra damnata, or *caput mortuum.*

Damson. The fruit of a variety of the *prunus domestica*, which see.

Dandelion. See *Leontodon Taraxacum.*

Dandrif. See *Pityriasis.*

Dane-wort. See *Sambucus Ebulus.*

DA'PHNE. (*Daphne*, *δαφνη*: from *δαω*, to burn, and *φωνη*, a noise; because of the noise it makes when burnt.) The name of a genus of plants in the Linnæan system. Class, *Octandria.* Order, *Monogynia.* The laurel, or bay-tree.

Da'phne alpi'na. *Chamælea. Chamelæa.* The herb widow-wail, or *Daphne alpina* of Linnæus. A sort of dwarf olive-tree; said to be purgative in the dose of ʒjj. The mezereon is also so called, because it has leaves like the olive-tree.

Daphne, flax-leaved. See *Daphne Gnidium.*

Da'phne gni'dium. The systematic name of the tree which affords the garou. *Thymelæa. Oneoron.* Spurge-flax. Flax-leaved Daphne. This plant, *Daphne gnidium; panicula terminali foliis lineari-lanceolatis acuminatis* of Linnæus, affords the *garou bark*, which very much resembles that of our mezereum. Garou bark is to be immersed in vinegar for about an hour before it is wanted; a small piece, the size of a sixpence, thus steeped, is applied to the arm or any other part, and renewed once a day in winter and twice in summer. It produces a serous exudation from the skin without irritating or blistering. It is recommended, and is in frequent use in France and Russia, against some diseases of the eyes.

Da'phne laure'ola. The systematic name of the spurge laurel. *Laureola.* Spurge laurel. The bark of this plant, *Daphne laureola* of Linnæus, is recommended to excite a discharge from the skin, in the same way as that of the *thymelæa.*

Da'phne meze'reum. The systematic name of the mezereon. *Mezereum.* Spurge-olive. Widow-wail. This plant, *Daphne mezereum floribus sessilibus ternis caulinis, foliis lanceolatis deciduis*, of Linnæus, is extremely acrid, especially when fresh, and, if retained in the mouth, excites great and long-continued heat and inflammation, particularly of the mouth and fauces; the berries also have the same effects, and, when swallowed, prove a powerful corrosive poison, not only to man, but to dogs, wolves, and foxes. The bark of the root is the part employed medicinally in the *decoctum sarsaparillæ compositum*, intended to assist mercury in resolving nodes and other obstinate symptoms of syphilis. The antisyphilitic virtues of mezereum, however, have been by many writers very justly doubted. The result of my own experience (says Mr. Pearson, of the Lock Hospital) by no means accords with the representation given of this root by former writers. From all that I have been able to collect, in the course of many years' observation, I feel myself authorised to assert, unequivocally, that the mezereum has not the power of curing the venereal disease in any one stage, or under any one form. If a decoction of this root should ever reduce a venereal node, where no mercury has been previously given, yet the patient will by no means be exempted from the necessity of employing mercury for as long a space of time, and in as large a quantity, as if no mezereum had been taken. With respect to the power it is said to possess, of alleviating the pain, and diminishing the bulk of membranous nodes, nothing peculiar and appropriate can be ascribed to the mezereum on these accounts, since we obtain the same good effects from sarsaparilla, guaiacum, volatile alkali, blistering plasters, &c. Nevertheless, venereal nodes, which have subsided under the use of any of these articles of the materia medica, will appear again, and often with additional symptoms, if a full and efficacious course of mercury be not submitted to. It has, indeed, been alleged that mezereum always alleviates the pain occasioned by a venereal node, and generally reduces it, where the periosteum only is affected; and that it seldom fails of removing those enlargements of the periosteum which have not yielded during the administration of mercury.

That some instances of success, in cases like these, may have fallen to the share of those who made the assertion, it would not become me to deny; but I have met with few such agreeable evidences of the efficacy of this medicine. I have given the mezereum in the form of a simple decoction, and also as an ingredient in compound decoctions of the woods, in many cases, where no mercury had been previously employed, but never with advantage to a single patient. I have also tried it, in numerous instances, after the completion of a course of mercury; yet, with the exception of two cases, where the thickened state of the periosteum was removed during the exhibition of it, I never saw the least benefit derived from taking this medicine. In a few cases of anomalous pains, which I supposed were derived from irregularities during a mercurial course, the mezereum was of service, after I had tried the common decoction of the woods without success; but even in this description of cases, I have always found it a very uncertain remedy. I have made trial of this vegetable in a great number of scrofulous cases, where the membranes covering the bones were in a diseased state, and I am not sure that one single patient obtained any evident and material benefit from it.

The late Dr. Cullen, whose reports may justly claim attention from all medical men, when treating of the mezereum, in his Materia Medica, says, "I have frequently employed it in several cutaneous affections, and sometimes with success." It were to have been wished, that the professor of medicine had specified what those diseases of the skin were, in which the mezereum was sometimes employed with success; for, if I except an instance or two of lepra, in which the decoction of this plant conferred a temporary benefit, I have very seldom found it possessed of medicinal virtue, either in syphilis, or in the sequelæ of that disease, in scrofula, or in cutaneous affections. Indeed the mezereum is of so acrimonious a nature, often producing heat and other disagreeable sensations in the fauces, and, on many occasions, disordering the primæ viæ, that I do not often subject my patients to the certain inconveniences which are connected with the primary effects of this medicine, as they are rarely compensated by any other important and useful qualities.

Daphnelæ'on. (From δαφνη, the laurel, and ελαιον, oil.) The oil of bay-berries.

Daphni'tis. (From δαφνη, the laurel.) A sort of cassia resembling the laurel.

Daphnoi'des. (From δαφνη, the laurel, and ειδος, a likeness.) The herb spurge laurel.

Da'rsin. (From *darzin*, Arab.) The grosser sort of cinnamon.

Da'rsis. (From δερω, to excoriate.) An excoriation.

DA'RTOS. (From δερω, to excoriate; so called from its raw and excoriated appearance.) The part so called, under the skin of the scrotum, is by some anatomists considered as a muscle, although it appears to be no more than a condensation of the cellular membrane lining the scrotum. It is by means of the dartos that the skin of the scrotum is corrugated and relaxed.

DARWIN, Erasmus, was born at Elton in Nottinghamshire, in 1731. After studying at Cambridge and Edinburgh, and becoming doctor of medicine, he went to settle at Litchfield. He had soon after the good fortune to succeed in the cure of a gentleman in the neighbourhood, who was so ill of a fever, as to have been given over by the physician previously in attendance: this speedily procured him very extensive practice. He soon after married, and by his first wife had three sons, of whom only one survived him. At the age of 50, he married again, and removed to Derby, where he continued till his death in 1802, leaving six children by his second wife. The active life he led, and his very temperate habits, preserved his health and faculties in a great degree unimpaired. He distinguished himself more as a poet, than by professional improvements: though he certainly suggested some ingenious methods of practice: but warned by preceding examples, he avoided publishing any material poem, till his medical fame was thoroughly established. His "Botanic Garden," and Zoonomia," are well known, but they have long ceased to be popular: and the philosophy of the latter work, which advocates materialism, is justly censured. He communicated to the College of Physicians an account of his successful use of digitalis in dropsy, and some other diseases, which was published in their Transactions. His son *Charles*, who died while studying at Edinburgh, obtained a gold medal by an Essay on the distinction of Pus and Mucus; and left another unfinished on the Retrograde Action of the Absorbents: which were published after his death by his father.

Dasy'mna. (From δασυς, rough.) A scabby roughness of the eye-lids.

Da'sys. (Δασυς, rough.) A dry, parched tongue. Difficult respiration.

Date plum, Indian. See *Diospyrus lotus.*

Date. See *Dactylus.*

DATU'RA. (Blanchard says it is derived from the Indian word *datiro*, of which he knows not the meaning.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Monogynia*.

Datu'ra stramo'nium. The systematic name of the thorn-apple. *Stramonium. Dutray. Barryo coccalon. Solanum mania-*

cum of Dioscorides, and *Stramonium spinosum* of Gerard. *Solanum fœtidum* of Bauhin. *Strammonium majus album*. Common thorn-apple. *Datura stramonium; pericarpiis spinosis erectis ovatis, foliis ovatis glabris*, of Linnæus. This plant has been long known as a powerful narcotic poison. In its recent state it has a bitterish taste, and a smell somewhat resembling that of poppies, especially if the leaves be rubbed between the fingers. Instances of the deleterious effects of the plant are numerous, more particularly of the seed. An extract prepared from the seeds is recommended by Baron Stoerck in maniacal, epileptic, and convulsive affections; and is said by some to succeed, while, in the hands of others, it has failed. In this country, says Dr. Woodville, we are unacquainted with any practitioners whose experience tends to throw light on the medical character of this plant. It appears to us, continues Dr. Woodville, that its effects as a medicine are to be referred to no other power than that of a narcotic. And Dr. Cullen, speaking on this subject, says, "I have no doubt that narcotics may be a remedy in certain cases of mania and epilepsy; but I have not, and I doubt if any other person has, learned to distinguish the cases to which such remedies are properly adapted. It is therefore that we find the other narcotics, as well as the stramonium, to fail in the same hands in which they had in other cases seemed to succeed. It is this consideration that has occasioned my neglecting the use of stramonium, and therefore prevented me from speaking more precisely from my own experience on this subject."

The extract of this plant has been the preparation usually employed from one to ten grains and upwards a day; but the powdered leaves, prepared after the manner of those of hemlock, would seem to be more certain and convenient. Greding found the strength of the extract to vary exceedingly; that which he obtained from Ludwig was much more powerful than that which he had of Stoerck. Externally, the leaves of stramonium have been applied to inflammatory tumours and burns, and it is said with success, and of late, the dried leaves have been smoked as a remedy in asthma; but it does not appear that they have been more efficacious in this way than tobacco.

DAUBENTON, LEWIS MARY, was born in Burgundy, 1716. Having become doctor of medicine at the age of 24, he went to Paris, and being very zealous in the study of comparative anatomy, the office of keeper of the royal cabinet of natural history was procured for him by the celebrated M. de Buffon. He contributed materially to enrich the splendid work of that eminent naturalist, by furnishing the anatomy both of man and animals. He was a member of several distinguished societies, among others of the Royal Academy of Sciences a Paris, to which he made some useful communications. Having escaped the revolutionary horrors in France, he was chosen, in 1799, a member of the Conservative Senate: but he died towards the end of the same year.

DAUCI'TES VI'NUM. Wild carrot-seeds steeped in must.

DAU'CUS. (Απο του δαυειν, from its relieving the colic, and discussing flatulencies.) The carrot.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Digynia*.

2. The pharmacopœial name of the garden carrot. See *Daucus carota*.

DAU'CUS ALSA'TICUS. The *oreoselinum pratense* of Linnæus.

DAU'CUS A'NNUUS MI'NOR. The *caucalis anthriscus* of Linnæus.

DAU'CUS CARO'TA. The systematic name of the carrot plant. *Daucus. Daucus sylvestris. Pastinaca sylvestris tenuifolia officinarum.* The cultivated root of the *Daucus carota; seminibus hispidis, petiolis subtus nervosis* of Linnæus, scraped and applied in the form of a poultice, is an useful application to phagedænic ulcers, and to cancers and putrid sores. The seeds, which obtain a place in the materia medica, have a light aromatic smell, and a warm acrid taste, and are esteemed for their diuretic qualities, and for their utility in calculous and nephritic complaints, in which an infusion of three spoonfuls of the seeds in a pint of boiling water, has been recommended; or the seeds may be fermented in malt liquor, which receives from them an agreeable flavour, resembling that of lemon-peel. The boiled root is said by many to be difficult of digestion; but this is the case only when the stomach is weak. It contains a considerable quantity of the saccharine principle, and is very nutritious.

DAU'CUS CRE'TICUS. See *Athamanta Cretensis*.

DAU'CUS SATI'VUS. A variety of the *daucus carota*, whose seeds are preferred by some practitioners.

DAU'CUS SEPRI'NIUS. Common chervil.

DAU'CUS SYLVE'STRIS. Wild carrot, or bird's nest. The seeds of the wild plant are said to be more efficacious than those of the garden carrot; they possess demulcent and aromatic qualities, and are given, in infusion, or decoction, in calculous complaints.

Dead nettle. See *Lamium album*.

Deadly nightshade. See *Atropa Belladonna*.

DEAFNESS. It is occasioned by any thing that proves injurious to the ear, as loud noises from the firing of cannon, violent colds, particularly affecting the head, inflammation or ulceration of the membrane, hard wax, or other substances interrupting sounds; too great a dryness, or too much moisture in the parts; or by atony, debility, or paralysis of the auditory nerves. In some instances it ensues in consequence of preceding diseases, such as fever, syphilis, &c. and in others it depends upon an original defect in the structure or formation of the ear. In the last instance, the person is usually not only deaf but likewise dumb. See *Paracusis*.

Dearticula'tio. (From *de*, and *articulus*, a joint.) Articulation admitting evident motion.

Deascia'tio. (From *de*, and *ascio*, to chip, as with a hatchet.) A bone splintered on its side.

Decamy'ron. (From δεκα, ten, and μυρον, an ointment.) An aromatic ointment, mentioned by Oribasius, containing ten ingredients.

Decide'ntia. (From *decido*, to fall down.) *Cataptosis.* Any change prolonging acute diseases.

DECI'DUA. (*Decidua*, sc. *membrana*; from *decido*, to fall down.) *Membrana decidua.* A very thin and delicate membrane or tunic, which adheres to the gravid uterus, and is said to be a reflexion of the chorion, and, on that account, is called *decidua reflexa*. The tunica decidua comes away after delivery, in small pieces, mixed with the *lochia*.

Decima'nus. (From *decem*, ten, and *mane*, the morning.) Returning every tenth day, applied to some erratic fevers.

Decli'vis. (From *de*, and *clivis*, a hill.) Declining, descending. A name of an abdominal muscle, because of its posture.

DECO'CTUM. (From *decoquo*, to boil.) A decoction. Any medicine made by boiling in a watery fluid. In a chemical point of view, it is a continued ebullition with water, to separate such parts of bodies as are only soluble at that degree of heat. The following are among the most approved decoctions.

Deco'ctum a'lbum. See *Mistura Cornu usti.*

Deco'ctum a'loes compo'situm. Compound decoction of aloes. Take of extract of liquorice, half an ounce; subcarbonate of potash, two scruples; extract of spiked aloe powdered, myrrh powdered, saffron stigmata, of each a drachm; water, a pint. Boil down to twelve fluid ounces, and strain; then add compound tincture of cardamoms, four fluid ounces. This decoction, now first introduced into the London Pharmacopœia, is analogous to an article in very frequent use, invented by the late Dr. Devalingin, and sold under the name of *beaume de vie*. By the proportion of tincture which is added, it will keep unchanged for any length of time.

Deco'ctum althæ'æ. Decoction of marsh mallows. Take of dried marsh mallow roots, ℥iv; raisins of the sun stoned, ʒjj; water, ℔vjj. Boil to five pounds; place apart the strained liquor, till the fæces have subsided, then pour off the clear part. This preparation, directed in the Edinburgh Pharmacopœia, may be exhibited as a common drink in nephralgia, and many diseases of the urinary passages, with advantage.

Deco'ctum anthe'midis. See *Decoctum chamæmeli.*

Deco'ctum astra'gali. Take of the root of the astragalus excapus, ℥j; distilled water, ℔jjj. These are to be boiled, till only a quart of fluid remain. The whole is to be taken, a little warmed, in the course of 24 hours. This remedy was tried very extensively in Germany, and said to evince very powerful effects, as an antisyphilitic.

Deco'ctum barda'næ. Take of bardana root, ℥vj; of distilled water, ℔vj. These are to be boiled till only two quarts remain. From a pint to a quart in a day is given, in those cases where sarsaparilla and other remedies that are called alterative are supposed to be requisite.

Deco'ctum chamæme'li. Chamomile decoction. Take of chamomile flowers, ℥j; caraway seeds, ℥ss; water, ℔v. Boil fifteen minutes, and strain. A very common and excellent vehicle for tonic powders, pills, &c. It is also in very frequent use for fomentation, and clysters.

Deco'ctum cincho'næ. Decoction of cinchona, commonly called decoction of Peruvian bark. Take of lance-leaved cinchona bark bruised, an ounce; water, a pint. Boil for ten minutes, in a vessel slightly covered, and strain the decoction while hot. According to the option of the practitioner, the bark of either of the other species of cinchona, the cordifolia, or *yellow*, or the oblongifolia, or *red*, may be substituted for the lancifolia, or *quilled*; which is here directed. This way of administering the bark is very general, as all the other preparations may be mixed with it, as necessity requires. It is a very proper fomentation for prolapsus of the uterus and rectum.

Deco'ctum co'rnu. See *Mistura Cornu usti.*

Deco'ctum cydo'niæ. *Mucilago seminis cydonii mali. Mucilago seminum cydoniorum.* Decoction of quince seeds. Take of quince seeds, two drachms; water, a pint. Boil over a gentle fire for ten minutes, then strain. This decoction, in the new London Pharmacopœia, has been removed from among the mucilages, as being less dense than either of the others, and as being employed in larger doses, like other mucilaginous decoctions. In addition to gum, it contains other constituent parts of the seeds, and is, therefore, more apt to spoil than common mucilage, over which it possesses no other advantages, than that it is more grateful, and sufficiently thin, without further dilution, to form the bulk of any liquid medicine. Its virtues are demulcent. Joined with syrup of mulberry, and a little borax, it is useful against aphthæ of the mouth and fauces.

Deco′ctum da′phnes meze′rei. Decoction of mezereon. Take of the bark of mezereon root, ℥jj; liquorice root bruised, ℥ss; water, ℔jjj. Boil it, with a gentle heat, down to two pounds, and strain it. From four to eight ounces of this decoction may be given four times a day, in some obstinate venereal and rheumatic affections. It operates chiefly by perspiration.

Deco′ctum dulcama′ræ. Decoction of woody nightshade. Take of woody nightshade stalks, newly gathered, ℥j; distilled water, ℔jss. These are to be boiled away to a pint, and strained. The dose is half an ounce to two ounces, mixed with an equal quantity of milk. This remedy is employed in inveterate cases of scrophula; in cancer and phagedæna; in lepra and other cutaneous affections; and in anomalous local diseases, originating in venereal lues.

Deco′ctum Geoffræ′æ ine′rmis. Decoction of cabbage-tree plant. Take of bark of the cabbage-tree, powdered, ℥j; water, ℔jj. Boil it, with a gentle fire, down to one pound, and strain. This is a powerful anthelmintic. It may be given in doses of one table-spoonful to children, and four to adults. If disagreeable symptoms should arise from an over-dose, or from drinking cold water during its action, we must immediately purge with castor-oil, and dilute with acidulated drinks.

Deco′ctum guai′aci officina′lis compo′situm. *Decoctum lignorum.* Compound decoction of guaiacum, commonly called decoction of the woods. Take of guaiacum raspings, ℥jjj; raisins stoned, ℥jj; sassafras root, liquorice, each ℥j; water, ℔x. Boil the guaiacum and raisins, with the water, over a gentle fire, to the consumption of one half; adding, towards the end, the sassafras and liquorice. Strain the liquor without expression. This decoction possesses stimulant and diaphoretic qualities, and is generally exhibited in rheumatic and cutaneous diseases, which are dependent on a vitiated state of the humours. It may be taken by itself, to the quantity of a quarter of a pint, twice or thrice a day, or used as an assistant in a course of mercurial or antimonial alteratives; the patient, in either case, keeping warm, in order to promote the operation of the medicine.

Deco′ctum helle′bori a′lbi. Decoction of white hellebore. Take of the root of white hellebore powdered, by weight, ℥j; water, two pints; rectified spirits of wine, ℥jj by measure. Boil the water, with the root, to one pint; and the liquor being cold and strained, add to it the spirit. This decoction, in the last London Pharmacopœia, is called decoctum veratri. It is a very efficacious application, externally, as a wash, in tinea capitis, lepra, psora, &c. When the skin is very tender and irritable, it should be diluted with an equal quantity of water.

Deco′ctum ho′rdei. *Decoctum hordei distichi. Aqua hordeata.* Take of pearl barley, ℥jj; water, four pints and a half. First wash away any adhering extraneous substances with cold water; next, having poured upon the barley half a pint of water, boil for a few minutes. Let this water be thrown away, and add the remainder of the water boiling; then boil down to two pints and strain. Barley water is a nutritive and softening drink, and the most proper of all liquors in inflammatory diseases. It is an excellent gargle in inflammatory sore throats, mixed with a little nitre.

Deco′ctum ho′rdei compo′situm. *Decoctum pectorale.* Compound decoction of barley. Take of decoction of barley, two pints; figs sliced, ℥jj; liquorice root, sliced and bruised, ℥ss; raisins stoned, ℥jj; water, a pint. Boil down to two pints, and strain. From the pectoral and demulcent qualities of this decoction, it may be administered as a common drink in fevers and other acute disorders, in catarrh, and several affections of the chest.

Deco′ctum ho′rdei cum gu′mmi. Barley water, ℔jj; gum arab. ℥j. The gum is to be dissolved in the barley decoction whilst warm. It then forms a suitable diluent in strangury, dysury, &c. for the gum, finding a passage into the bladder in an unaltered state, mixes with the urine, and prevents the action of its neutral salts on the urinary canal.

Deco′ctum Liche′nis. Decoction of liverwort. Take of liverwort, one ounce; water a pint and a half. Boil down to a pint, and strain. The dose is from ℥j to ℥iv.

Deco′ctum lobe′liæ. Take a handful of the roots of the lobelia syphilitica; distilled water, ℔xjj. These are to be boiled in the usual way, till only four quarts remain. The very desirable property of curing the venereal disease has been attributed to this medicine; but it is not more to be depended on than guaiacum, or other vegetable substances, of which the same thing has been alleged. The effects of this decoction are purgative; and the manner of taking it, as described by Swediaur, is as follows: — The patient is to begin with half a pint twice a day. The same quantity is then to be taken four times a day, and continued so long as its purgative effect is not too considerable. When the case is otherwise, it is to be discontinued for three or four days, and then had recourse to again till the cure is completed. As this is a remedy on the old system, and not admitted into our pharmacopœias, little confidence ought to be placed in it.

Deco′ctum Lusita′nicum. Take of sliced sarsaparilla, lignum sassafras, lignum santalum rubrum, officinal lignum guaiacum, of each one ounce and a half; of the root of mezereon, coriander seed, of each half an ounce; distilled water, ten pounds. These are to be boiled till only half the fluid remains. The dose is a quart or more in a day.

"Take of sliced sarsaparilla, lignum santalum rubrum, lignum santalum citrinum, of each ℥jss; of the root of glycyrrhiza and mezereon, of each ʒjj; of lignum rhodii, officinal lignum guaiacum, and lignum sassafras, of each ℥ss; of antimony, ℥j; distilled water, ℔v." These ingredients are to be macerated for twenty-four hours, and afterwards boiled, till the fluid is reduced to half its original quantity. From one to four pints are given daily.

The late Mr. Hunter notices this and also the following formula, in his Treatise on the Venereal Disease.

"Take of sliced sarsaparilla, of the root of China, of each ℥j; walnut peels dried, xx; antimony, ℥jj; pumice-stone, powdered, ℥j; distilled water, ℔x. The powdered antimony and pumice-stone are to be tied in separate pieces of rag, and boiled along with the other ingredients." This last decoction is reckoned to be the genuine Lisbon diet drink, whose qualities have been the subject of so much encomium.

Deco′ctum ma′lvæ compo′situm. *Decoctum pro enemate. Decoctum commune pro clystere.* Compound decoction of mallows. Take of mallows dried, an ounce; chamomile flowers dried, half an ounce; water, a pint. Boil for a quarter of an hour, and strain. A very excellent form for an emollient clyster. A variety of medicines may be added to answer particular indications.

Deco′ctum meze′rei. See *Decoctum daphnes mezerei.*

Deco′ctum papa′veris. *Decoctum pro fomento. Fotus communis.* Decoction of poppy. Take of white poppy capsules bruised, ℥iv; water, four pints. Boil for a quarter of an hour, and strain. This preparation possesses sedative and antiseptic properties, and may be directed with advantage in sphacelus, &c.

Deco′ctum pro ene′mate. See *Decoctum malvæ compositum.*

Deco′ctum pro fome′nto. See *Decoctum papaveris.*

Deco′ctum que′rcus. Decoction of oak bark. Take of oak bark, ℥j; water, two pints. Boil down to a pint, and strain. This astringent decoction has lately been added to the Lond. Pharm. and is chiefly used for external purposes. It is a good remedy in prolapsus ani, and may be used also in some cases as an injection.

Deco′ctum sarsapari′llæ. Decoction of sarsaparilla. Take of sarsaparilla root, sliced, ℥iv; boiling water, four pints. Macerate for four hours, in a vessel lightly covered, near the fire; then take out the sarsaparilla and bruise it. After it is bruised, put it again into the liquor, and macerate it in a similar manner for two hours more; then boil it down to two pints, and strain.

This decoction is much extolled by some practitioners, in phthisis, and to restore the strength after a long course of mercury.

Deco′ctum sarsapari′llæ compo′situm. Compound decoction of sarsaparilla. Take of decoction of sarsaparilla, boiling, four pints; sassafras root sliced, guaiacum wood shavings, liquorice root bruised, of each an ounce; mezereon root bark, ʒjjj. Boil for a quarter of an hour, and strain. The alterative property of the compound is very great; it is generally given after a course of mercury, where there have been nodes and indolent ulcerations, and with great benefit. The dose is from half a pint to a pint in twenty-four hours.

Deco′ctum se′negæ. Decoction of senega. Take of senega root, ℥j; water, two pints. Boil down to a pint, and strain. This is now first introduced into the Lond. Pharm. as being a useful medicine, especially in affections of the lungs, attended with debility and inordinate secretion.

Deco′ctum u′lmi. Decoction of elm bark. Take of fresh elm bark bruised, four ounces; water, four pints. Boil down to two pints, and strain. This may be employed with great advantage as a collyrium in chronic ophthalmia. It is given internally in some cutaneous eruptions.

Deco′ctum vera′tri. See *Decoctum hellebori albi.*

Decolla′tio. (From *decollo*, to behead.) The loss of a part of the skull.

DECOMPOSITION. A separation of parts. See *Analysis.*

Decortication. (From *de*, from, and *cortex*, bark.) The stripping of any thing of its bark, husk, or shell: thus almonds, and the like, are decorticated, that is, deprived of their pellicle, when ordered for medicinal purposes.

DECREPITATION. (From *decrepo*, to crackle.) A kind of crackling noise, which takes place in bodies when heated: it is peculiar to some kinds of salts; as muriate of soda, &c.

DECUSSATION. (From *decutio*, to divide.) When nerves, or muscular fibres, cross one another, they are said to decussate each other.

Decusso′rium. (From *decusso*, to divide.) An instrument to depress the dura mater, after trepanning.

Defensi′va. (From *defendo*, to preserve.) Cordial medicines, or such as resist infection.

DE′FERENS. (From *defero*, to convey; because it conveys the semen to the vesiculæ seminales.) See *Vas deferens.*

DEFLAGRATION. (From *deflagro*, to burn.) Calcination. A chemical term, chiefly employed to express the burning or setting fire to any substance; as nitre, sulphur, &c.

DEFLUXION. (From *defluo*, to run off.) *Defluxio.* A falling down of humours from a superior to an inferior part. Many writers mean nothing more by it than inflammation.

DEGLUTITION. (From *deglutio*, to swallow down.) A natural action, by which the masticated bole or a fluid is conveyed from the mouth into the fauces, and from thence through the œsophagus into the stomach.

De′gmus. (From δακνω, to bite.) A biting pain in the orifice of the stomach.

DEIDIER, Anthony, was son of a surgeon of Montpelier. Having graduated in medicine in 1691, he was six years after made professor of chemistry. In 1732, being appointed physician to the Galleys, he went to Marseilles, where he died in 1746. He published, among many other works on different branches of medicine, "Experiments on the Bile, and the Bodies of those who died of the Plague," which occurred while he was at Marseilles. He states that he tried mercurial inunctions, but they had no effect on the disease. There are three volumes of consultations and observations by him deserving of perusal. The rest of his works are scarcely now referred to.

Deje′ctio alvi′na. Discharge of excrement by stool.

Dejecto′ria. (From *dejicio*, to cast out.) Purging medicines.

Deino′sis. (From δεινοω, to exaggerate.) An enlargement of the supercilia.

Delachrymati′va. (From *de*, and *lachryma*, a tear.) Medicines which dry the eyes, first purging them of tears.

Dela′psio. (From *delabor*, to slip down.) A falling down of the anus, uterus, or intestines.

DELETERIOUS. (*Deleterius*; from δηλεω, to hurt or injure.) Those substances are so called which are of a poisonous nature.

DELIQUESCENCE. Deliquation, or the gradual melting down of crystallized salts, from exposure to the air.

Deli′quium a′nimi. (*Deliquium*; from *delinquo*, to leave.) See *Syncope*.

DELI′RIUM. (From *deliro*, to rave.) A febrile symptom, consisting in the persons acting or talking unreasonably. It is to be carefully distinguished from an alienation of the mind, without fever.

Deloca′tio. (From *de*, from, and *locus*, a place.) A dislocation, or putting any part out of its proper place.

DELPHI′NIUM. (From δελφινος, the dolphin.) Larkspur; so called from the likeness of its flower to the dolphin's head. The name of a genus of plants in the Linnæan system. Class, *Polyandria*. Order, *Trigynia*.

Delphi′nium conso′lida. The systematic name of the *consolida regalis*. *Calcatrippa.* Many virtues are attributed to this plant, *Delphinium consolida; nectariis monophyllis, caule subdiviso*, of Linnæus. The flowers are bitter, and a water distilled from them is recommended in ophthalmia. The herb has been administered in calculous cases, obstructed menses, and visceral diseases.

Delphi′nium staphisa′gria. The systematic name of stavesacre. *Staphisagria. Staphis. Pedicularia.* Stavesacre. *Delphinum staphisagria; nectariis tetraphyllis petalo brevioribus, foliis palmatis, lobis obtusis*, of Linnæus. The seeds, which are the only parts directed for medicinal use, are usually imported here from Italy; they are large, rough, of an irregular triangular figure, and of a blackish colour on the outside, but yellowish within; their smell is disagreeable, and somewhat fetid; to the taste they are very bitter, acrid, and nauseous. It was formerly employed as a masticatory, but is now confined to external use, in some kinds of cutaneous eruptions, but more especially for destroying lice and other insects; hence by the vulgar it is called louse-wort.

De′lphys. Δελφυς. The uterus, or pudendum muliebre.

De′lta. (The Greek letter, Δ.) The external pudendum muliebre is so called, from the triangular shape of its hair.

DELTOI′DES. (From δελτα, the Greek letter Δ, and ειδος, a likeness; shaped like the Greek delta.) *Sous-acromio-clavi-humeral* of Dumas. A muscle of the superior extremity, situated on the shoulder. It arises exactly opposite to the trapezius, from one-third part of the clavicle, from the acromion and spine of the scapula, and is inserted, tendinous, into the middle of the os humeri, which bone it lifts up directly; and it assists with the supraspinatus and coracobrachialis in all the actions of the humerus, except the depression; it being convenient that the arm should be raised and sustained, in order to its moving on any side.

Deme′ntia. (From *de*, and *mens*, without mind.) Madness. Delirium. Absence of intellect.

DEMULCENTS. (*Demulcentia*, sc. *medicamenta*; from *demulceo*, to soften.) Medicines suited to obviate and prevent the action of acrid and stimulant matters; and that not by correcting or changing their acrimony, but by involving it in a mild and viscid matter, which prevents it from acting upon the sensible parts of our bodies, or by covering the surface exposed to their action.

Where these substances are directly applied to the parts affected, it is easy to perceive how benefit may be derived from their application. But where they are received by the medium of the stomach, into the circulating system, it has been supposed that they can be of no utility, as they must lose that viscidity on which their lubricating quality depends. Hence it has been concluded that they can be of no service in gonorrhœa, and some similar affections. It is certain, however, says J. Murray, in his Elements of Materia Medica and Pharmacy, that many substances which undergo the process of digestion are afterwards separated, in their entire state, from the blood, by particular secreting organs, especially by the kidneys; and it is possible, that mucilaginous substances, which are the principal demulcents, may be separated in this manner. There can be no doubt, however, but that a great share of the relief demulcents afford, in irritation or inflammation of the urinary passages, is owing to the large quantities of water in which they are diffused, by which the urine is rendered less stimulating from dilution. In general, demulcents may be considered merely as substances less stimulating than the fluids usually applied.

Catarrh, diarrhœa, dysentery, calculus, and gonorrhœa, are the diseases in which demulcents are employed. As they are medicines of no great power, they may be taken in as large quantities as the stomach can bear.

The particular demulcents may be reduced to the two divisions of mucilages and expressed oils. The principal demulcents are, the acacia vera, astragalus, tragacantha, linum usitatissimum, althæa officinalis, malva sylvestris, glycyrrhiza glabra, cycas circinalis, orchis mascula, maranta arundinacea, triticum hybernum, ichthyocolla, olea Europæa, amygdalus communis, cetaceum, and cera.

Dendroli′banus. (From *δενδρον*, a tree, and *ολιϐανος*, frankincense.) The herb rosemary, or frankincense-tree.

DENS. (*Dens, -tis*, m. *Quasi edens*; from *edo*, to eat, or from *οδους, οδοντος*.) A tooth. See *Teeth*.

Many herbs have this specific name, from their fancied resemblance to the tooth of some animal; as *dens leonis*, the dandelion; *dens canis*, dog's tooth, &c.

Dens leonis. See *Leontodon Taraxacum*.

Denta′gra. (*Dentagra, οδονταγρα*: from *οδους*, a tooth, and *αγρα*, a seizure.) The tooth-ache; also an instrument for drawing the teeth.

DENTA′RIA. (*Dentaria*, from *dens*, a tooth; so called because its root is denticulated.) See *Plumbago Europæa*.

Dentarpa′ga. (From *οδους*, a tooth, and *αρπαζω*, to fasten upon.) An instrument for drawing of teeth.

Denta′ta. See *Dentatus*.

DENTA′TUS. (From *dens*, a tooth; from its tooth-like process.) *Dentata. Epistrophæus*. The second vertebra of the neck. It differs from the other cervical vertebræ, by having a tooth-like process at the upper part of the body. See *Vertebræ*.

Dentella′ria. (From *dentella*, a little tooth; so called because its root is denticulated.) The herb tooth-wort. See *Plumbago Europæa*.

De′ntes inciso′res. See *Teeth*.

De′ntes cani′ni. See *Canine teeth*.

De′ntes la′ctei. The milk-teeth. See *Teeth*, and *Dentition*.

De′ntes mola′res. See *Teeth*.

Dentidu′cum. (From *dens*, a tooth, and *duco*, to draw.) An instrument for drawing of teeth.

DENTIFRICE. (From *dens*, a tooth, and *frico*, to rub.) A medicine to clean the teeth.

Dentisca′lpium. (From *dens*, a tooth, and *scalpo*, to scrape.) An instrument for scaling teeth.

DENTITION. (From *dentio*, to breed teeth.) The breeding or cutting of the teeth. The first dentition begins about the sixth or seventh month, and the teeth are termed the *primary* or *milk* teeth. About the seventh year, these fall out, and are succeeded by others, which remain during life, and are called the *secondary* or *perennial* teeth. The last dentition takes place between the ages of twenty and five-and-twenty, when the four last grinders appear; they are called *dentes sapientæ*. See also *Teeth*.

Dentodu′cum. See *Dentiducum*.

Denuda′tio. (From *denudo*, to make bare.) A laying bare the bone.

DEOBSTRUENTS. (*Deobstruentia*, sc. *medicamenta*; from *de*, and *obstruo*, to obstruct.) Medicines that are exhibited with a view of removing any obstruction.

Deoppila′ntia. (From *de*, and *oppilo*, to stop.) *Deoppilativa*. Medicines which remove obstructions; deobstruent or aperitive medicines.

Departi′tio. (From *de*, and *partior*, to divide.) Separating metals.

Deperdi′tio. (From *deperdo*, to lose.) Abortion, or the undue loss of the fœtus.

Depeti′go. (From *de*, and *petigo*, a running scab.) A ring-worm, or tetter. A scurf, or itch, where the skin is rough.

Dephlegma′tio. (From *de*, and *phlegma*, phlegm.) The operation of rectifying or freeing spirits from their watery parts.

DEPILATORY. (*Depilatoria*, sc. *unguenta*; from *de*, of, and *pilus*, the hair.) Any application which removes the hairs from any part of the body; thus, a pitch cap pulls the hairs of the head out by the roots.

Deplu′matio. (From *de*, and *pluma*, a feather.) A disease of the eyelids, which causes the hair to fall off.

Deprehe′nsio. (From *deprehendo*, to catch unawares.) The epilepsy is so called, from the suddenness with which persons are seized with it.

Depre′ssio. (From *deprimo*, to press down.) Depression. When the bones of the skull are forced inwards by fracture, they are said to be depressed.

DEPRE′SSOR. (From *deprimo*, to press down.) Several muscles are so termed, because they depress the part on which they act.

Depre′ssor a′læ na′si. See *Depressor labii superioris alæque nasi.*

DEPRE′SSOR A′NGULI O′RIS. *Triangularis* of Winslow. *Depressor labiorum communis* of Douglas. *Depressor labiorum* of Cowper. *Sous-maxillo-labial* of Dumas. A muscle of the mouth and lip, situated below the under lip. It arises, broad and fleshy, from the lower edge of the lower jaw, near the chin; and is inserted into the angle of the mouth, which it pulls downwards.

DEPRE′SSOR LA′BII INFERIO′RIS. *Quadratus* of Winslow. *Depressor labii inferioris proprius* of Douglas and Cowper. *Mentonier labial* of Dumas. A muscle of the mouth and lip, that pulls the under lip and skin of the side of the chin downwards, and a little outwards.

DEPRE′SSOR LA′BII SUPERIO′RIS ALÆ′QUE NA′SI. *Depressor alæ nasi* of Albinus. *Incisivus medius* of Winslow. *Depressor labii superioris proprius* of Douglas. *Constrictores alarum nasi, ac depressores labii superioris* of Cowper. *Maxillo-alveoli nasal* of Dumas. A muscle of the mouth and lip, situated above the mouth, that draws the upper lip and ala nasi downwards and backwards. It arises, thin and fleshy, from the superior maxillary bone, immediately above the joining of the gums, with the two incisor teeth and cuspidatus; from thence it runs upwards, and is inserted into the upper lip and root of the ala of the nose.

Depre′ssor la′bii superio′ris pro′prius. See *Depressor labii superioris alæque nasi.*

Depre′ssor labio′rum commu′nis. See *Depressor anguli oris.*

Depre′ssor o′culi. See *Rectus inferior oculi.*

De′primens. See *Rectus inferior oculi.*

Depura′ntia. (From *depuro*, to make clean.) Medicines which evacuate impurities.

DEPURATION. The freeing a liquor or solid body from its foulness.

Depurato′rius. (From *de*, and *purus*, pure.) It is applied to fevers, which terminate in perspiration.

De′ris. (Δερις: from δερω, to excoriate.) The skin.

DERIVATION. (From *derivo*, to drain off.) The doctrines of derivation and revulsion, talked of by the antients, are now, in their sense of the terms, wholly exploded. Derivation means the drawing away any disease from its original seat to another part.

De′rma. (Δερμα.) The skin.

Dermato′des. (From δερμα, skin, and ειδος, a likeness.) Resembling skin, or leather, in its consistence. It is applied to the dura mater.

DERMATOLO′GIA. (From δερμα, the skin, and λογος, a discourse.) A discourse or treatise on the skin.

De′rtron. (From δερις, skin.) The omentum, or peritonæum, is so named, from its skin-like consistence.

DESAULT, Peter, was a native of Bourdeaux, where he graduated, and became distinguished as a practitioner in medicine about the beginning of the last century. He was author of some popular and useful dissertations on medical subjects. In syphilis he maintained that a cure could be effected without salivation; and in calculous complaints by the patient drinking the Bareges water, this being also injected into the bladder; but it probably merely palliated the symptoms. He exposed also some of the prevailing errors concerning hydrophobia; as that the patient barked like a dog, and had a propensity to bite his attendants. The precise period of his death is not mentioned.

DESAULT, Peter Joseph, was chief surgeon to the Hôtel-Dieu at Paris. He published several numbers of a surgical journal in 1791, &c.; also jointly with M. Chopart, in 1794, "A Treatise on Chirurgical Diseases, and the Operations required in their Cure;" which is allowed to have considerable merit. He attended the young King of France, Lewis XVII., in the Temple; and died under suspicious circumstances shortly before his royal patient in 1795.

Descenso′rium. (From *descendo*, to move downwards.) A vessel in which the distillation by descent is performed.

Desce′nsus. (From *descendo*, to move downwards.) The same chemists call it a distillation *per descensum*, by descent, when the fire is applied at the top and round the vessel, whose orifice is at the bottom.

DESICCATI′VA. (From *desicco*, to dry up.) Such medicines as, being applied outwardly, dry up the humours and moisture running from a wound.

Desipie′ntia. (From *desipio*, to dote.) A defect of reason. Symptomatic phrenzy.

De′sme. (From δεω, to bind up.) A bandage, or ligature.

Desmi′dion. (From δεσμη, a handful.) A small bundle, or little bandage.

De′smos. (From δεω, to bind up.) A bandage. An inflammatory stricture of a joint, after luxation.

DESPUMATION. (From *despumo*, to clarify.) The clarifying a fluid, or separating its foul parts from it.

DESQUAMATION. (From *desquamo*, to scale off.) The separating of laminæ, or scales, from a bone. Exfoliation.

Desquamato′rium. (From *desquamo*, to scale off.) A trepan, or instrument to take a piece out of the skull.

Destilla′tion. See *Distillation.*

Desuda′tio. (From *desudo*, to sweat much.) An unnatural and morbid sweating.

Dete'ntio. (From *detineo*, to stop, or hinder.) Epilepsy is so called, from the suddenness with which the patient is seized.

DETERGENTS. (From *detergo*, to wipe away.) Medicines which cleanse and remove such viscid humours as adhere to and obstruct the vessels. Also such applications as clear away foulness from ulcers.

DETONATION. (From *detono*, to make a noise.) Explosion.

Detra'ctor. (From *detraho*, to draw.) Applied to a muscle, whose office is to draw the part to which it is attached.

De'trahens quadra'tus. See *Platysma myoides*.

DETRU'SOR URI'NÆ. (From *detrudo*, to thrust out.) The name of a muscle whose office is to squeeze out the urine. The muscular coat of the urinary bladder was formerly so called.

Deu'teri. (From δευτερος, second; because it is discharged next after the fœtus.) The secundines, or after-birth.

Deuteropa'thia. (From δευτερος, second, and ϖαθος, a suffering.) An affection or suffering by consent, where a second part suffers, from consent, with the part originally affected, as where the stomach is disturbed through a wound in the head.

DEVENTER, Henry, was born in Holland, towards the end of the 17th century. He took a degree in medicine, but his practice was principally in surgery, and at last almost confined to midwifery. He distinguished himself much by his improvements in this art, as well as by his mechanical inventions for obviating deformities in children. He published some obstetrical works several years prior to his death, which occurred in 1739; after which appeared a Treatise on the Rickets in his native language, of which Haller makes favourable mention.

Devil's dung. See *Ferula assafœtida*.

Diabe'bus. (From διαϐεϐαιοω, to strengthen; so called, as affording the chief support to the foot.) The ankle-bone.

DIABE'TES. (From δια, through, and βαινω, to pass.) An immoderate flow of urine. A genus of disease in the class *neuroses*, and order *spasmi* of Cullen. There are two species of this complaint: 1. *Diabetes insipidus*, in which there is a superabundant discharge of limpid urine, of its usual urinary taste. 2. *Diabetes mellitus*, in which the urine is very sweet, and contains a great quantity of sugar. Great thirst, with a voracious appetite, gradual emaciation of the whole body, and a frequent discharge of urine, containing a large proportion of saccharine and other matter, which is voided in a quantity even exceeding that of the aliment or fluid introduced, are the characteristics of this disease. Those of a shattered constitution, and those who are in the decline of life, are most subject to its attacks. It not unfrequently attends on hysteria, hypochondriasis, dyspepsia, and asthma; but it is always much milder when symptomatic, than when it appears as a primary affection.

Diabetes may be occasioned by the use of strong diuretic medicines, intemperance of life, and hard drinking; excess in venery, severe evacuations, or by any thing that tends to produce an impoverished state of the blood, or general debility. It has, however, taken place, in many instances, without any obvious cause.

That which immediately gives rise to the disease, has ever been considered as obscure, and various theories have been advanced on the occasion. It has been usual to consider diabetes as the effect of relaxation of the kidneys, or as depending on a general colliquation of the fluids. Dr. Richter, professor of medicine in the university of Goettingen, supposes the disease to be generally of a spasmodic nature, occasioned by a stimulus acting on the kidneys; hence a *secretio aucta urinæ*, and sometimes *perversa*, is the consequence. Dr. Darwin thinks that it is owing to an *inverted* action of the urinary branch of the lymphatics; which doctrine, although it did not escape the censure of the best anatomists and experienced physiologists, met, nevertheless, with a very favourable reception, on its being first announced. The late Dr. Cullen offered it as his opinion, that the proximate cause of this disease might be some fault in the assimilatory powers, or in those employed in converting alimentary matters into the proper animal fluids, which theory has since been adopted by Dr. Dobson, and still later by Dr. Rollo, surgeon-general to the royal artillery. The liver has been thought, by some, to be the chief source of the disease; but diabetes is hardly ever attended with any affection of this organ, as has been proved by frequent dissections; and when observed, it is to be considered as accidental.

The primary seat of the disease is, however, far from being absolutely determined in favour of any hypothesis yet advanced; and, from the most attentive consideration of all the circumstances, the weight of evidence appears to induce the majority of practitioners to consider diabetes as depending on a primary affection of the kidneys.

Diabetes sometimes comes on slowly and imperceptibly, without any previous disorder; and it now and then arises to a considerable degree, and subsists long without being accompanied with evident disorder in any particular part of the system; the great thirst which always, and the voracious appetite which frequently occur in it, being often the only remarkable symptoms; but it more generally happens, that a considerable affection of the stomach precedes the coming on of the disease; and that, in its progress, besides the symptoms already mentioned, there is a great dryness in the skin, with a sense of weight in the kidneys, and a pain in the ureters, and the other urinary passages.

Under a long continuance of the disease, the body becomes much emaciated, the feet œdematous, great debility arises, the pulse is frequent and small, and an obscure fever, with all the appearance of hectic, prevails.

The urine in diabetes, from being at first insipid, clear, and colourless, soon acquires a sweetish or saccharine taste, its leading characteristic: and, when subjected to experiment, a considerable quantity of saccharine matter is to be extracted from it.

In some instances, the quantity of urine is much greater than can be accounted for from all the sources united. Cases are recorded, in which 25 to 30 pints were discharged in the space of a natural day, for many successive weeks, and even months; and in which the whole ingesta, as was said, did not amount to half the weight of the urine. To account for this overplus, it has been alleged that water is absorbed from the air by the surface of the body; as also that a quantity of water is compounded in the lungs themselves.

Dissections of diabetes have usually shewn the kidneys to be much affected. In some instances, they have been found in a loose flabby state, much enlarged in size, and of a pale ash colour; in others, they have been discovered much more vascular than in an healthy state, approaching a good deal to what takes place in inflammation, and containing, in their infundibula, a quantity of whitish fluid, somewhat resembling pus, but without any sign of ulceration whatever. At the same time that these appearances have been observed in their interior, the veins on their surface were found to be much fuller of blood than usual, forming a most beautiful net-work of vessels, the larger branches of which exhibited an absorbent appearance. In many cases of dissection, the whole of the mysentery has been discovered to be much diseased, and its glands remarkably enlarged; some of them being very hard, and of an irregular texture; others softer, and of an uniform spherical shape. Many of the lacteals have likewise been seen considerably enlarged. The liver, pancreas, spleen, and stomach, are in general perceived to be in a natural state; when they are not so, the occurrence is to be considered as accidental. The bladder, in many cases, is found to contain a considerable quantity of muddy urine.

A great variety of remedies has been proposed for this disease; but their success is generally precarious, or only temporary, at least in the mellitic form of the complaint. The treatment has been generally conducted on the principles of determining the fluids to other outlets, particularly the skin, and of increasing the tone of the kidneys. Diaphoretics are certainly very proper remedies, especially the combination of opium with ipecacuanha, or antimonials, assisted by the warm bath, suitable clothing, and perhaps removal to a milder climate: in the insipid form of diabetes, this plan has sometimes effected a cure; and it appears that the large use of opium has even the power of correcting, for the time, the saccharine quality of the urine. Cathartics are hardly of service, farther than to keep the bowels regular. Tonics are generally indicated by obvious marks of debility; and if the patient be troubled with acidity in the primæ viæ, alkaline medicines will be properly joined with them, preferring those which have no diuretic power. Astringents have been highly extolled by some practitioners, but do not appear likely to avail, except those which pass off by the urine, as uva ursi; or the milder stimulants, which can be directed to the kidneys, as copaiba, &c. may correct the laxity of those organs, if the disease depend on this cause. The tinctura lyttæ must be used with great caution, and its efficacy is not well established: and blisters to the loins can only be useful as counter-irritants, though not the most suitable. Frequent friction, especially over the kidneys, wearing a tight belt, and gentle exercise, may assist the recovery of the patient; and when the function of the skin is restored, using the bath gradually of a lower temperature, will tend greatly to obviate its suppression afterwards. It is likewise highly important to regulate the diet, especially in the mellitic diabetes. Dr. Rollo first pointed out the advantage derived from restricting the patient to a diet principally of animal food, avoiding especially those vegetables which might afford saccharine matter, the urine becoming thereby of a more healthy quality, and diminishing in quantity: but unfortunately the benefit appears but temporary, and the plan is not persevered in without distress to the patient. The same gentleman recommended also the sulphuret of potash, and still more the hydrosulphuret of ammonia; but they are very nauseous medicines, and of doubtful efficacy. Another plan of treating the disease has been more recently proposed, namely, by bleeding, and other antiphlogistic measures; and some cases of its success have been recorded: but farther experience is certainly required, before we should be justified in relying much upon it.

Diabe'tes hyste'ricus. Large discharge of urine in hysterical women.

Dia'bolus metallo'rum. Tin.

Diabo'tanum. (From δια, and βοτανη, a herb.) A plaster made of herbs.

Diaca'dmias. (From δια, and καδμια, cadmia.) The name of a plaster whose basis is cadmia.

Diacalami′nthes. (From δια, and καλαμινθη, calamint.) The name of an antidote, whose chief ingredient is calamint.

Diaca′rcinum. (From δια, and καρκινος, a crab.) The name of an antidote prepared from the flesh of crabs and cray-fish.

Diaca′ryon. (From δια, and καρυον, a nut.) Rob of nuts, or walnuts.

Diaca′ssia. (From δια, and κασσια, cassia.) Electuary of cassia.

Diacasto′rium. (From δια, and καϛωρ, castor.) An antidote whose basis is castor.

Diacatho′licon. (From δια, and καθολικος, universal.) The name of a purge, so called from its general usefulness.

Diacentau′rium. (From δια, and κενταυριον, centaury.) The Duke of Portland's powder is so called, because its chief ingredient is centaury.

Diacentro′tum. (From δια, and κεντροω, to prick.) A collyrium, so called from its pungency and stimulating qualities.

Diachalci′tis. (From δια, and χαλκιτις, chalcitis.) A plaster whose chief ingredient is chalcitis.

Diacha′lsis. (From διαχαλω, to be relaxed.) A relaxation. The opening of the sutures of the head.

Diacheiri′smus. (From δια, and χειρ, the hand.) Any operation performed by the hand.

Diachelido′nium. (From δια, and χελιδωνιον, celandine.) A plaster whose chief ingredient was the herb celandine.

Diachore′ma. (From διαχωρεω, to separate from.) *Diachoresis.* Any excretion, or excrement, but chiefly that by stool.

Diachore′sis. See *Diachorema.*

Diachri′sta. (From δια, and χριω, to anoint.) Medicines to anoint sore or bruised parts.

Diachry′sum. (From δια, and χρυσος, gold.) A plaster for fractured limbs; so named from its yellow colour.

Dia′chylum. (From δια, and χυλος, juice.) The plaster of this name was formerly made of certain juices, but it now means an emollient digestive plaster.

Dia′chysis. (From δια, and χυω, to pour out.) Fusion or melting.

Diachy′tica. (From διαχυω, to dissolve.) Medicines which discuss and dissolve tumours.

Diacine′ma. (From δια, and κινεω, to move.) A slight dislocation.

Diaci′ssum. (From δια, and κισσος, ivy.) An application composed of ivy-leaves.

Dia′clasis. (From δια, and κλαω, to break.) A small fracture.

Diacly′sma. (From διακλυζω, to wash out.) A gargarism, or wash for the mouth.

Diacoccyme′lon. (From δια, and κοκκυμηλον, a plum.) An electuary made of prunes.

Diaco′dium. (From δια, and κωδια, a poppy head.) A composition made of the heads of poppies.

Diacolocy′nthis. (From δια, and κολοκυνθις, the colocynth.) A preparation whose chief ingredient is colocynth.

Diaco′mma. (From διακοπτω, to cut through.) *Diacope.* A deep cut or wound.

Dia′cope. See *Diacomma.*

Diacopræ′gia. (From δια, κοπρος, dung, and αιξ, a goat.) A preparation with goat's dung.

Diacora′llum. (From δια, and κοραλλιον, coral.) A preparation in which coral is a chief ingredient.

Dia′crisis. (From διακρινω, to distinguish.) The distinguishing diseases one from another by their symptoms.

Diacro′cium. (From δια, and κροκος, saffron.) A collyrium in which is saffron.

Diacurcu′ma. (From δια, and κυρκουμα, turmeric.) An antidote in which is turmeric or saffron.

Diacydo′nium. (From δια, and κυδωνια, a quince.) Marmalade of quinces.

Diadaphni′dion. (From δια, and δαφνις, the laurel-tree.) A drawing-plaster in which were bay-berries.

Diade′ma. (From διαδεω, to surround.) A diadem or bandage to put round the head.

Diade′xis. (From διαδεχομαι, to transfer.) *Diadoche.* A transposition of humours from one place to another.

Dia′doche. See *Diadexis.*

Dia′dosis. (From διαδιδωμι, to distribute.) The remission of a disorder.

Diæ′resis. (From διαιρεω, to divide or separate.) A solution of continuity of the soft parts of the human body.

Diære′tica. (From διαιρεω, to divide.) Corrosive medicines.

DIÆ′TA. (From διαιταω, to nourish.) Diet; food. It means also the whole of the non-naturals. See *Diet.*

Diaglau′cium. (From δια, and γλαυκιον, the blue juice of a herb.) An eye-water made of the purging thistle.

DIAGNO′SIS. (From διαγινωσκω, to discern or distinguish.) The science which delivers the signs by which a disease may be distinguished from another disease; hence those symptoms which distinguish such affections are termed *diagnostic.*

Diagry′dium. Corrupted from dacrydium or scammony.

Diahermoda′ctylum. (From δια, and ερμοδακτυλος, the hermodactyl.) A purging medicine whose basis is the hermodactyl.

Diai′reon. (From δια, and ιρις, the lily.) An antidote in which is the root of the lily.

Diai′um. (From δια, and ιον, a violet.) A pastil whose chief ingredient is violets.

Diala′cca. (From δια, and λακκα.) An antidote in which is the lacca.

Dialago′um. (From δια, and λαγως, a hare.) A medicine in which is the dung of a hare.

Diale′mma. (From *διαλαμβανω*, to interrupt.) The remission of a disease.

Diale′psis. (From *διαλαμβανω*, to interrupt.) An intermission. Also a space left between a bandage.

Diali′banum. (From *δια*, and *λιϐανον*, frankincense.) A medicine in which frankincense is a chief ingredient.

Dia′loes. (From *δια*, and *αλοη*, the aloe.) A medicine chiefly composed of aloes.

Dialthæ′a. (From *δια*, and *αλθαια*, the mallow.) An ointment composed chiefly of mallows.

DIA′LYSIS. (From *διαλυω*, to dissolve.) A solution of continuity, or a destruction of parts.

DIA′LYSES. An order in the class *locales* of Cullen's nosology.

Dialy′tica. (From *διαλυω*, to dissolve.) Medicines which heal wounds and fractures.

Diamargari′ton. (From *δια*, and *μαργαριτης*, pearl.) An antidote in which pearls are the chief ingredient.

Diamasse′ma. (From *δια*, and *μασσομαι*, to chew.) A masticatory, or substance put into the mouth and chewed to excite a discharge of the saliva.

Dia′mbra. (From *δια*, and *αμϐρα*, amber.) An aromatic composition in which was ambergris.

Diame′lon. (From *δια*, and *μηλον*, a quince.) A composition in which are quinces.

Diami′syos. (From *δια*, and *μισυ*, misy.) A composition in which misy is an ingredient.

DIAMOND. The diamond, which was well known to the antients, is principally found in the western peninsula of India, on the coast of Coromandel, in the kingdoms of Golconda and Visapour, in the island of Borneo, and in the Brazils.

They are generally found bedded in yellow ochre, or in rocks of free-stone, or quartz, and sometimes in the beds of running waters. When taken out of the earth, they are incrusted with an exterior earthy covering, under which is another, consisting of carbonate of lime.

In the Brazils, it is supposed that diamonds might be obtained in greater quantities than at present, if the sufficient working of the diamond-mines was not prohibited, in order to prevent that dimunition of their commercial value, which a greater abundance of them might occasion.

Brazilian diamonds are, in commercial estimation, inferior to the oriental ones.

In the rough, diamonds are worth two pounds sterling the carat, or four grains, provided they are without blemish. The expense of cutting and polishing amounts to about four pounds more. The value however is far above what is now stated when they become considerable in size.

The usual method of calculating the value of diamonds is by squaring the number of carats, and then multiplying the amount by the price of a single carat; thus supposing one carat to be 2*l.* a diamond of 8 carats is worth 128*l.* being 8 × 8 × 2.

The famous Pigot diamond weighs 188 1-8th grains.

Physical Properties of Diamond.

Diamond is always crystallized, but sometimes so imperfectly, that at first sight it might appear amorphous. The figure of diamond, when perfect, is an eight-sided prism. There are also cubical, flat, and round diamonds. It is the oriental diamond which crystallizes into octohedra, and exhibits all the varieties of this primitive figure. The diamond of Brazil crystallizes into dodecahedra.

The texture of the diamond is lamellated, for it may be split or cleft with an instrument of well-tempered steel, by a swift blow in a particular direction. There are however some diamonds which do not appear to be formed of *laminæ*, but of twisted and interwoven fibres, like those of knots in wood. These exceed the others greatly in hardness, they cannot be cut or polished, and are therefore called by the lapidaries *diamonds of nature*.

The diamond is one of the hardest bodies known. It resists the most highly-tempered steel file, which circumstance renders it necessary to attack it with diamond powder. It takes an exquisite and lasting polish. It has a great refractive power, and hence its lustre, when cut into the form of a regular solid, is uncommonly great. The usual colour of diamonds is a light grey, often inclining to yellow, at times lemon colour, violet, or black, seldomer rose-red, and still more rarely green or blue, but more frequently pale brown. The purest diamonds are perfectly transparent. The colourless diamond has a specific gravity which is in proportion to that of water as 3.512 to 1.000, according to Brisson. This varies however considerably. When rubbed it becomes *positively* electric, even before it has been cut by the lapidary.

Diamond is not acted upon by acids, or by any chemical agent, oxygen excepted; and this requires a very great increase of temperature to produce any effect.

The diamond burns by a strong heat, with a sensible flame, like other combustible bodies, attracting oxygen, and becoming wholly converted into carbonic acid gas during that process.

It combines with iron by fusion, and converts it, like common charcoal, into steel; but diamond requires a much higher temperature for its combustion than common charcoal does, and even then it consumes but slowly, and ceases to burn the instant its temperature is lowered.

It is considered by modern chemists as *pure crystallized carbon*. See *Carbon*.

Diamo′ron. (From *δια*, and *μωρον*, a mulberry.) A preparation of mulberries.

Diamo'schum. (From δια, and μοσχος, musk.) An antidote in which musk is a chief ingredient.

Diamoto'sis. (From δια, and μοτος, lint.) The introduction of lint into an ulcer or wound.

Dia'na. (A name of the moon.) The chemical name for silver from its white shining appearance.

Diananca'smus. (From δια, and αναγκαζω, to force.) The forcible restoration of a luxated part into its proper place. An instrument to reduce a distorted spine.

DIA'NTHUS. (From Διs, διος, Jove, and ανθος, a flower: so called from the elegance and fragrance of its flowers.) The name of a genus of plants in the Linnæan system. Class, *Decandria*. Order, *Digynia*.

Dia'nthus caryophy'llus. The systematic name of the clove-pink. *Caryophyllum rubrum. Tunica. Vetonica. Betonica. Coronaria. Caryophyllus hortensis.* Clove pink. Clove gilliflower. Clove July flower. This fragrant plant, *Dianthus caryophyllus: floribus solitariis, squamis calycinis subovatis, brevissimis, corollis crenatis,* of Linnæus, grows wild in several parts of England; but the flowers, which are pharmaceutically employed, are usually produced in gardens: they have a pleasant aromatic smell, somewhat allied to that of clove-spice; their taste is bitterish and sub-adstringent. These flowers were formerly in extensive use, but are now merely employed in form of syrup, as a useful and pleasant vehicle for other medicines.

Diapa'sma. (From διαπασσω, to sprinkle.) A medicine reduced to powder and sprinkled over the body, or any part.

Diapede'sis. (From διαπηδαω, to leap through.) The transudation or escape of blood through the coats of an artery.

Diape'gma. (From διαπηγνυω, to close together.) A surgical instrument for closing together broken bones.

Diape'nte. (From δια, and πεντε, five.) A medicine composed of five ingredients.

DIAPHANOUS. (From δια, through, and φαινω, to shine.) A term applied to any substance which is transparent; as the hyaloid membrane covering the vitreous humour of the eye, which is as transparent as glass.

Diaphœ'nicum. (From δια, and φοινιξ, a date.) A medicine made of dates.

Dia'phora. (From διαφερω, to distinguish.) The distinction of diseases by their characteristic marks and symptoms.

DIAPHORE'SIS. (From διαφορεω, to carry through.) Perspiration or increased cutaneous secretion.

DIAPHORETICS. (*Diaphoretica, sc. medicamenta;* from διαφορεω, to carry through.) Medicines which, from being taken internally, increase the discharge by the skin. When this is carried so far as to be condensed on the surface, it forms sweat; and the medicines producing it are named sudorifics. Between diaphoretics and sudorifics there is no distinction; the operation is in both cases the same, and differs only in degree from augmentation of dose, or employment of assistant means. This class of medicines comprehends five orders: 1. *Pungent diaphoretics,* as the *volatile salts,* and *essential oils,* which are well adapted for the aged; those in whose system there is little sensibility; those who are difficultly affected by other diaphoretics; and those whose stomachs will not bear large doses of medicines. 2. *Calefacient diaphoretics,* such as *serpentaria contrayerva,* and *guaiacum:* these are given in cases where the circulation is low and languid. 3. *Stimulant diaphoretics,* as antimonial and mercurial preparations, which are best fitted for the vigorous and plethoric. 4. *Antispasmodic diaphoretics,* as *opium, musk,* and *camphire,* which are given to produce a diaphoresis, when the momentum of the blood is increased. 5. *Diluent diaphoretics,* as water, whey, &c. which are best calculated for that habit in which a predisposition to sweating is wanted; and in which no diaphoresis takes place, although there be evident causes to produce it.

DIAPHRA'GMA. (*-matis,* n.: from δια, and φραττω, to divide.) *Septum transversum.* The midrif, or diaphragm. A muscle that divides the thorax from the abdomen. It is composed of two muscles; the first and superior of these arises from the sternum, and the ends of the last ribs on each side. Its fibres, from this semicircular origination, tend towards their centre, and terminate in a tendon, or aponeurosis, which is termed the *centrum tendinosum.* The second and inferior muscle comes from the vertebræ of the loins by two productions, of which that on the right side comes from the first, second, and third vertebræ of the loins; that on the left side is somewhat shorter, and both these portions join and make the lower part of the diaphragm, which joins its tendons with the tendon of the other, so that they make but one muscular partition. It is covered by the pleura on its upper side, and by the peritoneum on the lower side. It is pierced in the middle, for the passage of the vena cava; in its lower part for the œsophagus, and the nerves, which go to the upper orifice of the stomach, and betwixt the productions of the inferior muscle, passes the aorta, the thoracic duct, and the vena azygos. It receives arteries and veins called phrenic or diaphragmatic, from the cava and aorta; and sometimes on its lower part two branches from the vena adiposa, and two arteries from the lumbares. It has two nerves which come from the third vertebra of the neck, which pass through the cavity of the thorax, and are lost in its substance. In its natural situation, the diaphragm is convex on the upper side towards the breast, and concave on its lower side towards the belly: therefore, when its fibres swell and contract, it must become plain on each side, and consequently the cavity of the breast is enlarged to give liberty to the lungs to receive air in inspiration; and the stomach and intestines are pressed for the distribution of their contents; hence the use of this muscle is very considerable; it is the principal agent in respiration, particularly in inspiration; for when it is in action the cavity of the thorax is enlarged, particularly at the sides, where the lungs are chiefly situated; and as the lungs must always be contiguous to the inside of the thorax and upper side of the diaphragm, the air rushes into them, in order to fill up the increased space. In expiration it is relaxed and pushed up by the pressure of the abdominal muscles upon the viscera of the abdomen; and at the same time that they press it upwards, they pull down the ribs, by which the cavity of the thorax is diminished, and the air suddenly pushed out of the lungs.

Diaphragmati'tis. (From διαφραγμα, the diaphragm.) *Diaphragmitis. Paraphrenitis.* An inflammation of the diaphragm. See *Paraphrenitis.*

Diaphragmi'tis. See *Paraphrenitis.*

Dia'phthora. (From διαφθειρω, to corrupt.) An abortion where the fœtus is corrupted in the womb.

Diaphyla'ctica. (From διαφυλασσω, to preserve.) Medicines which resist putrefaction or prevent infection.

Dia'physis. (From διαφυω, to divide.) An interstice or partition between the joints.

Diapisselæ'um. (From δια, and πισσελαιον, the oil of pitch, or liquid pitch.) A composition in which is liquid pitch.

Dia'plasis. (From διαπλασσω, to put together.) The replacing a luxated or fractured bone in its proper situation.

Diapla'sma. (From διαπλασσω, to anoint.) An unction or fomentation applied to the whole body or any part.

Dia'pne. (From διαπνεω, to blow through, or pass gently as the breath does.) An involuntary and insensible discharge of the urine.

Dia'pnoe. (From διαπνεω, to breathe through.) The transpiration of vapour through the pores of the skin.

Diapno'ica. (From διαπνεω, to transpire.) Diaphoretics or medicines which promote perspiration.

Diapore'ma. (From διαπορεω, to be in doubt.) Nervous anxiety.

Diapo'ron. (From δια, and οπωρα, autumnal fruits.) A composition in which are several autumnal fruits, as quinces, medlars, and services.

Diapra'ssium. (From δια, and πρασσιον, horehound.) A composition of horehound.

Diapru'num. (From δια, and προυνη, a prune.) An electuary of prunes.

Diapso'ricum. (From δια, and ψωρα, the itch or scurvy.) A medicine for the itch or scurvy.

Diapte'rnes. (From δια, and πτερνα, the heel.) A composition of cow heels and cheese.

Diaptero'sis. (From δια, and πτερον, a feather.) The cleaning the ears with a feather.

Diapye'ma. (From δια, and πυον, pus.) A suppuration or abscess.

Diapye'mata. (From διαπυημα, a suppuration.) Suppurating medicines.

Diapye'tica. (From διαπυημα, a suppuration.) See *Diapyemata.*

Diarho'cha. (From δια, and ρηχος, a space.) The space between the foldings of a bandage.

Dia'rius. (From *dies*, a day.) A term applied to fevers which last but one day.

Diaroma'ticum. (From δια, and αρωματικον, an aromatic.) A composition of spices.

Dia'rrhage. (From διαρρηγνυμι, to break asunder.) A fracture of the temple bones.

Diarrhodo'meli. (From δια, ροδον, a rose, and μελι, honey.) Scammony, agaric, pepper and honey.

Dia'rrhodon. (From δια, and ροδον, a rose.) A composition of roses.

DIARRHŒ'A. (From διαρρεω, to flow through.) A purging. It is distinguished by frequent stools with the natural excrement, not contagious, and seldom attended with pyrexia. It is a genus of disease in the class *neuroses*, and order *spasmi* of Cullen, containing the following species: 1. *Diarrhœa crapulosa.* The feculent diarrhœa, from *crapulus*, one who overloads his stomach. 2. *Diarrhœa biliosa.* The bilious, from an increased secretion of bile. 3. *Diarrhœa mucosa.* The mucous, from a quantity of slime being voided. 4. *Diarrhœa hepatirrhœa.* The hepatic, in which there is a quantity of serous matter, somewhat resembling the washings of flesh, voided; the liver being primarily affected. 5. *Diarrhœa lienterica.* The lientery; when the food passes unchanged. 6. *Diarrhœa cœliaca.* The cœliac passion: the food passes off in this affection in a white liquid state like chyle. 7. *Diarrhœa verminosa.* Arising from worms. Diarrhœa seems evidently to depend on an increase of the peristaltic motion, or of the secretion of the intestines; and besides the causes already noticed, it may arise from many others, influencing the system generally, or the particular seat of the disease. Of the former kind are cold, checking perspiration, certain passions of the mind, and other disorders, as dentition, gout, fever, &c. To the latter belong various acrid ingesta, drastic cathartics, spontaneous acidity, &c. In this complaint each discharge is usually preceded by a murmuring noise, with a sense of weight and uneasiness in the hypogastrium. When it is protracted, the stomach usually becomes affected with sickness, or sometimes vomiting, the countenance grows pale or sallow, and the skin generally dry and rigid. Ultimately great debility and emaciation, with dropsy of the lower extremities, often supervene. Dissections of diarrhœa, where it terminated fatally, have shewn ulcerations of the internal surface of the intestines, sometimes to a considerable extent, especially about the follicular glands; in which occasionally a cancerous character has been observable. The treatment of this complaint must vary greatly according to circumstances: sometimes we can only hope to palliate, as when it occurs in the advanced period of phthisis pulmonalis; sometimes it is rather to be encouraged, relieving more serious symptoms, as a bilious diarrhœa coming on in fever, though still some limits must be put to the discharge. Where, however, we are warranted in using the most speedy means of stopping it, the objects are, 1. To obviate the several causes. 2. To lessen the inordinate action, and give tone to the intestine.

I. Emetics may sometimes be useful, clearing out the stomach, and liver, as well as determining to the skin. Cathartics also, expelling worms, or indurated fæces; but any acrimony in the intestine would probably cause its own discharge, and where there is much irritability, they might aggravate the disease: however, in protracted cases, the alvine contents speedily become vitiated, and renew the irritation; which may be best obviated by an occasional mild aperient, particularly rhubarb. If, however, the liver do not perform its office, the intestine will hardly recover its healthy condition; and that may most probably be effected by the cautious use of mercury. Likewise articles which determine the fluids to other outlets, diuretics, and particularly diaphoretics, in many cases contribute materially to recovery; the latter perhaps assisted by bathing, warm clothing, gentle exercise, &c. Diluent, demulcent, antacid, and other chemical remedies, may be employed to correct acrimony, according to its particular nature. In children teething, the gums should be lanced; and if the bowels have been attacked on the repulsion of some other disease, it may often be proper to endeavour to restore this. But a matter of the greatest importance is the due regulation of the diet, carefully avoiding those articles, which are likely to disagree, or irritate the bowels, and preferring such as have a mild astringent effect. Fish, milk, and vegetables, little acescent, as rice, bread, &c. are best; and for the drink, madeira or brandy, sufficiently diluted rather than malt liquors.

II. Some of the means already noticed will help to fulfil the second indication also, as a wholesome diet, exercise, diaphoretics, &c.: but there are others of more power, which must be resorted to in urgent cases. At the head of these is opium, a full dose of which frequently at once effects a cure; but where there is some more fixed cause, and the complaint of any standing, moderate quantities repeated at proper intervals will answer better, and other subsidiary means ought not to be neglected; aromatics may prevent its disordering the stomach, rhubarb obviate its causing permanent constipation, &c. Tonics are generally proper, the discharge itself inducing debility, and where there is a deficiency of bile particularly, the lighter forms of the aromatic bitters, as the infusum calumbæ, &c. will materially assist; and mild chalybeates are sometimes serviceable. In protracted cases astringents come in aid of the general plan, and where opium disagrees, they may be more necessary: but the milder ones should be employed at first, the more powerful only where the patient appears sinking. Chalk and lime-water answer best where there is acidity; otherwise the pomegranate rind, logwood extract, catechu, kino, tormentil, &c. may be given: where these fail, alum, sulphate of zinc, galls, or superacetate of lead.

DIARTHRO'SIS. (From *διαρθροω*, to articulate.) A moveable connection of bones. This genus has five species, viz. enarthrosis, arthrodia, ginglymus, trochoides, and amphiarthrosis.

Diasapo'nium. (From *δια*, and *σαπων*, soap.) An ointment of soap.

Diasaty'rium. (From *δια*, and *σατυριον*, the orchis.) An ointment of the orchis-root.

Diasci'llium. (From *δια*, and *σκιλλα*, the squill.) Oxymel and vinegar of squills.

Diasci'ncus. (From *δια*, and *σκιγκος*, the crocodile.) A name for the mithridate, in the composition of which there was a part of the crocodile.

Diasco'rdium. (From *δια*, and *σκορδιον*, the water germander.) Electuary of scordium.

Diase'na. (From *δια*, and *sena*.) A medicine in which is senna.

Diasmy'rnum. (From *δια*, and *σμυρνη*, myrrh.) A collyrium containing myrrh.

Diaso'stica. (From *διασωζω*, to preserve.) Medicines which preserve health.

Diaspe'rmatum. (From *δια*, and *σπερμα*, seed.) A medicine composed chiefly of seeds.

Dia'sphage. (From *διασφαζω*, to separate.) *Diasphaxis.* The interstice between two veins.

Diasphy'xis. (From *δια*, and *σφυζω*, to strike.) The pulsation of an artery.

DIA'STASIS. (From *διιστημι*, to separate.) *Diastema.* A separation. A separation of the ends of bones.

Diaste'aton. (From *δια*, and *ϛεαρ*, fat.) An ointment of the fat of animals.

Diaste'ma. See *Diastasis.*

DIA'STOLE. (From *δια*, and *στελλω*,

to stretch.) The dilatation of the heart and arteries.

Diastomo'sis. (From διαϛομοω, to dilate.) Any dilatation, or dilating instrument.

Diastre'mma. (From διαϛρεφω, to turn aside.) *Diastrophe.* A distortion of any limb or part.

Dia'strophe. See *Diastremma.*

Dia'tasis. (From διατεινω, to distend.) The extension of a fractured limb, in order to reduce it.

Diatecoli'thum. (From δια, and τηκολιθος, the Jew's stone.) An antidote containing lapis judaicus.

Diatere'sis. (From δια, and τερεω, to perforate.) A perforation or aperture.

Diatere'tica. (From δια, and τερεω, to preserve.) Medicines which preserve health and prevent disease.

Diate'ssaron. (From δια, and τεσσαρες, four.) A medicine compounded of four simple ingredients.

Diate'ttigum. (From δια, and τεττιξ, a grasshopper.) A medicine in the composition of which were grasshoppers.

DIA'THESIS. (From διατιθημι, to dispose.) Any particular state of the body: thus, in inflammatory fever, there is an inflammatory diathesis, and, during putrid fever, a putrid diathesis.

Diathe'smus. (From διαθεω, to run through.) A rupture through which some fluid escapes.

Diatragaca'nthum. (From δια, and τραγακανθα, tragacanth.) A medicine composed of gum-tragacanth.

Dia'trium. (From δια, and τρεις, three.). A medicine composed of three simple ingredients.

Diaxyla'loes. (From δια, and ξυλαλοη, the lignum aloes.) A medicine in which is lignum aloes.

Diazo'ma. (From διαζωννυμι, to surround; because it surrounds the cavity of the thorax.) The diaphragm.

Diazo'ster, (From διαζωννυμι, to surround; because when the body is girded, the belt usually lies upon it.) A name of the twelfth vertebra of the back.

Dicente'tum. (From δια, and κεντεω, to stimulate.) A pungent stimulating collyrium.

Dichaste'res. (From διχαζω, to divide, because they divide the food.) A name of the foreteeth.

Dichophy'ia. (From διχα, double, and φυω, to grow.) A distemper of the hairs, in which they split and grow forked.

DICROTIC. (*Dicroticus,* sc. *pulsus;* from δις, twice, and κρουω, to strike.) A term given to a pulse in which the artery rebounds after striking, so as to convey the sensation of a double pulsation.

Dictamni'tes. (From δικταμνος, dittany.) A wine medicated with dittany.

DICTA'MNUS. (From *Dictamnus,* a city in Crete, on whose mountains it grows.) The name of a genus of plants in the Linnæan system. Class, *Decandria.* Order, *Monogynia.* Dittany.

Dicta'mnus a'lbus. White fraxinella, or bastard dittany. *Fraxinella. Dictamnus albus; foliis pinnatis, caule simplici,* of Linnæus. The root of this plant is the part directed for medicinal use; when fresh, it has a moderately strong, not disagreeable smell. Formerly it was much used as a stomachic, tonic, and alexipharmic, and was supposed to be a medicine of much efficacy in removing uterine obstructions and destroying worms; but its medicinal powers became so little regarded by modern physicians, that it had fallen almost entirely into disuse, till Baron Stoerck brought it into notice, by publishing several cases of its success, viz. in tertian intermittents, worms (lumbrici), and menstrual suppressions. In all these cases, he employed the powdered root to the extent of a scruple twice a-day. He also made use of a tincture, prepared of two ounces of the fresh root digested in 14 ounces of spirit of wine; of this 20 to 50 drops two or three times a-day, were successfully employed in epilepsies, and, when joined with steel, this root, we are told, was of great service to chlorotic patients. The dictamnus undoubtedly, says Dr. Woodville, is a medicine of considerable power; but notwithstanding the account of it given by Stoerck, who seems to have paid little attention to its modus operandi, we may still say with Haller "*nondum autem vires pro dignitate exploratus est,*" and it is now fallen into disuse.

Dicta'mnus cre'ticus. See *Origanum dictamnus.*

Didymæ'a. (From διδυμος, double.) A cataplasm; so called by Galen, from the double use to which he put it.

Di'dymi. (From διδυμος, double.) Twins. An old name of the testicles, and two eminences of the brain, from their double protuberance.

Diecbo'lium. (From δια, and εκϐαλλω, to cast out.) A medicine causing an abortion.

Diele'ctron. (From δια, and ελεκτρον, amber.) A name of a troche, in which amber is an ingredient.

DIEMERBROECK, Isbrand, was born near Utrecht, in 1609. After graduating at Angers, he went to Nimeguen in 1636, and for some years continued freely attending those, who were ill of the plague, which raged with great violence, and of which he subsequently published an account. This obtained him much credit: and in 1642 he was made professor extraordinary in medicine at Utrecht; when he gave lectures on that subject, as well as on anatomy, which rendered him very popular. He received also other distinctions at that university, and continued in high esteem till his death in 1674. He was author besides of a system of anatomy, and several other works in medicine and surgery; part of which were published after his death by his son, especially his treatise on the measles and small-pox.

Dierví'lla. (Named in honour of Mr. Dierville, who first brought it from Arcadia.) See *Lonicera diervilla*.

DIET. *Diæta*. The dietetic part of medicine is no inconsiderable branch, and seems to require a much greater share of regard than it commonly meets with. A great variety of diseases might be removed by the observance of a proper diet and regimen, without the assistance of medicine, were it not for the impatience of the sufferers. However, it may on all occasions come in as a proper assistant to the cure, which sometimes cannot be performed without a due observance of the non-naturals. That food is, in general, thought the best and most conducive to long life, which is most simple, pure, and free from irritating qualities, and such as approaches nearest to the nature of our own bodies in a healthy state, or is capable of being easiest converted into their substance by the vis vitæ, after it has been duly prepared by the art of cookery; but the nature, composition, virtues, and uses of particular aliments can never be learnt to satisfaction, without the assistance of practical chemistry.

DIET DRINK. An alterative decoction employed daily in considerable quantities, at least from a pint to a quart. The decoction of sarsaparilla and mezereon, the Lisbon diet drink, is the most common and most useful.

DIETE'TICS. That part of medicine which considers the way of living with relation to food, or diet, suitable to any particular case.

Die'xodos. (From δια, and εξοδος, a way to pass out.) *Diodos*. In Hippocrates it means evacuation by stool.

Diffla'tio. (From *difflo*, to blow away.) Perspiration.

DIGA'STRICUS. (*Digastricus*, sc. *musc.* from δις, twice, and γαστηρ, a belly.) *Biventer maxillæ* of Albinus. *Mastoido-hygenien* of Dumas. A muscle so called from its having two bellies, situated externally between the lower jaw and *os hyoides*. It arises, by a fleshy belly, from the upper part of the processus mastoideus, and descending, it contracts into a round tendon, which passes through the stylohyoideus, and an annular ligament which is fastened to the os hyoides: then it grows fleshy again, and ascends towards the middle of the edge of the lower jaw, where it is inserted. Its use is to open the mouth by pulling the lower jaw downwards and backwards; and when the jaws are shut, to raise the larynx, and consequently the pharynx, upwards, as in deglutition.

Digere'ntia. (From *digero*, to digest.) Medicines which promote the secretion of proper pus in wounds and ulcers.

DIGESTION. (*Digestio*, from *digero*, to dissolve.)

1. An operation in which such matters as are intended to act slowly on each other, are exposed to a slow heat, continued for some time.

2. The change that the food undergoes in the stomach, by which it is converted into chyme. The circumstances necessary to effect a healthy digestion of the food are, 1. A certain degree of heat of the stomach. 2. A free mixture of saliva with the food in the mouth. 3. A certain quantity of healthy gastric juice. 4. The natural peristaltic motion of the stomach. 5. The pressure of the contraction and relaxation of the abdominal muscles and diaphragm. From these circumstances, the particles of the food are softened, dissolved, diluted, and intimately mixed into a soft pap, called chyme, which passes through the pylorus of the stomach into the duodenum. The fluid, which is termed gastric juice, is separated by the minute arteries opening into the cavity of the stomach. See *Gastric Juice*. From various experiments of physiologists, it is ascertained that the gastric juice reduces the aliments into an uniform pap or paste, even out of the body; that it acts in the same manner after death; and that it is the chief agent in the process of digestion.

Animals only are invested with organs of digestion; every one, from man to the polypus, presents an alimentary canal differently formed; the existence of a digestive apparatus, then, could be given as an essential character of animal life. In man, this consists of a long canal extending from the mouth to the anus, into which open the excretory ducts of various glands, situated in the vicinity, that secrete liquors, necessary to alter, liquefy, and animalise alimentary matter.

It would be useless to recapitulate the hypotheses formed to explain digestion; they may be reduced to *coction*, *fermentation*, *trituration*, *putrefaction*, and *maceration* of the food received into the cavity of the stomach. Physiologists are generally agreed, at present, in considering digestion in the stomach as a solution of the aliment by the gastric juice. This liquid, copiously poured on the internal surface of the stomach, when this viscus is irritated by the presence of food, is the production of arterial exhalation; it is neither an acid nor alkali, and seems to be of a nature nearly analogous to saliva; the gastric juice possessing great solvent properties, penetrates into the alimentary matter on all sides, separates and divides its particles, combines with it, changes its composition, and impresses qualities very different from thos it possessed before this mixture. In fact, if a mouthful of wine or food be returned from the stomach some minutes after it has been received, the odour, taste, and all the qualities, both physical and chemical, of these substances, are so altered, that we can with difficulty distinguish them; and vinous liquors, more or less acid, are no longer susceptible of spirituous fermentation. The energy of the power of the gastric juice, perhaps exaggerated by some physiologists, is sufficient to reduce to a soft mass the hardest bones, on which certain animals subsist: it is very probable that its chemical composition is different and variable, and that it is acid, alkaline, or saponaceous, according to the nature of the aliment. Although gastric juice is the most powerful agent of digestion in the stomach, its dissolvent power has need of assistance from the action of several secondary causes, as heat, which seems to augment and concentrate itself in the epigastric region. So long as the exertion of the stomach continues, there is a sort of intestine fermentation, which should not however be, in the full sense, compared to the motion by which fermentative and putrescent substances are decomposed; there is also a moderate and peristaltic motion of the muscular fibres of the stomach which press the aliment on all sides, and perform a slight trituration, while the gastric moisture softens and macerates the food before it is dissolved; it may then be affirmed that the process of digestion is at the same time chemical, vital, and mechanical; the authors, therefore, of various theories to explain this function, have erred by attributing to one cause only, as heat, fermentation, putrefaction, trituration, maceration, and the gastric juice, that which is the aggregate result of all those causes united.

The aliment remains a greater or less time in the stomach, agreeably to the facility or difficulty of the necessary changes taking place. Gosse, of Geneva, has proved on himself, that the animal and vegetable fibre, the white of an egg boiled, white and tendinous parts, paste kneaded with butter, sebaceous substances, and those things which are not fermented, or very little fementative, make greater resistance to the gastric juice, than the gelantinous parts of vegetables and animals, fermented bread, &c. that the latter class of substances require only an hour for their complete dissolution, while the digestion of the former was not completed at the end of several hours.

During the time of digestion, both orifices of the stomach are closed; no gas, disengaged from the aliment, ascends through the œsophagus, unless in cases of bad digestion: slight chills are felt; the pulse becomes quicker and stronger, and the powers of life seem diminished in some organs, to be carried to the seat of the digestive process. The parietes of the stomach soon begin to act: their circular fibres contract in different parts of its extent; these peristaltic oscillations, at first vague and uncertain, become more regular, and are directed from above downwards, from left to right, that is, from the cardia towards the pylorus; its longitudinal fibres also contract, and thus approximate both terminations. In these different motions, the stomach becomes parallel with the pylorus, and the angle formed by the duodenum is almost totally obliterated, which renders the passage of food easier. It has been remarked, that digestion proceeds better during sleep, when we lie on the right side than on the left, and this difference has been attributed to the compression made by the liver on the stomach. It should rather be considered, that on the right side, the passage of food is accelerated by its own gravity, the situation of the stomach is naturally oblique, from left to right, and becomes more so in consequence of changes induced by food.

The aperture of the pylorus is furnished with a muscular ring, covered by a duplicature of mucous membrane; this kind of sphincter keeps it closed during the time of digestion in the stomach, and does not give passage to the aliment until it has undergone a very material alteration. The pylorus, possessing a peculiar and extremely delicate sensibility, may be considered as a sort of vigilant centinel, that prevents any thing from passing that has not suffered proper changes. Many authors quoted by Haller, have been well aware that the food did not pass from the stomach successively in the same manner as it was received, but agreeably to its greater or less facility of digestion.

It would appear that there is a real selection of food in the stomach, for those aliments that admit of an easy digestion are directed towards the pylorus, which gives passage to them: while, on the contrary, such as are not sufficiently digested are not permitted to pass, but kept back in the stomach. This delicate feeling, which we attribute to the pylorus, this exquisite sense, by which it exerts a kind of choice on the food that passes through, may be perhaps objected to; pieces of money, however, or other extraneous indigestible bodies, remain a longer or shorter time in the stomach before they go into the intestines, and present themselves several different times at the orifice of the pylorus, and do not get through till after it has been accustomed to their contact. It is the same with the gastric system as with a secreting gland; and in the same manner the commencement of excretory ducts, possessed of a sort of *elective* sensibility, do not receive the secreted liquor before it has undergone necessary preparations in the glandular parenchyma; so the pylorus, which may be considered the excretory duct of the stomach, does not admit the food nor suffer it to pass into the intestines, until it has been sufficiently elaborated by the action of this organ.

In proportion as the stomach becomes empty, the spasm of the skin ceases, a moderate heat succeeds the shiverings, the pulse becomes more evident and elevated, the quantity of insensible perspiration increases; digestion then produces a general motion, analogous to a feverish paroxysm; and this digestive fever, described also by the antients, is most easy to be observed in women of great sensibility. Nothing positive can be established on the duration of digestion in the stomach. The aliments go out of the stomach with more or less celerity, in proportion as they offer a greater or less resistance to those powers which serve to dissolve them, and agreeably to the energy and strength of the stomach and activity of the gastric juice; five hours, however, may be considered the ordinary time of their presence.

The action of the parietes of the stomach ceases when this viscus is entirely liberated from the aliments that were in its cavity, but not before; the gastric juice, the secretion of which is not augmented by any stimulus, is no longer poured out by its arteries; and the parietes, which come into contact with each other, are only lubricated by the mucus copiously secreted by its internal coat.

DIGESTIVES. (*Digestiva*, sc. *medicamenta;* from *digero*, to dissolve.) A term applied by surgeons to those substances which, when applied to an ulcer or wound, promote suppuration: such are the *ceratum resinæ flavæ*, *unguentum elemi*, warm poultices, fomentations, &c.

Digesti′vum sal sy′lvii. See *Potassæ Murias.*

DIGITA′LIS. (From *digitus*, a finger; because its flower represents a finger.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia*. Order, *Angiospermia*. Fox-glove.

2. The pharmacopœial name of the common fox-glove. See *Digitalis purpurea.*

Digita′lis purpurea. The systematic name of the fox-glove; — *Digitalis calycinis foliolis ovatis acutis, corollis obtusis, labio superiore integro*, of Linnæus. The leaves of this plant have a bitter nauseous taste, but no remarkable smell; they have been long used externally to ulcers and scrophulous tumours with considerable advantage. When properly dried, their colour is a lively green. They ought to be collected when the plant begins to blossom, to be dried quickly before the fire, and preserved unpowdered.

Of all the narcotics, digitalis is that which diminishes most powerfully the actions of the system; and it does so without occasioning any previous excitement. Even in the most moderate dose, it diminishes the force and frequency of the pulse, and, in a large dose, reduces it to a great extent, as from 70 beats to 40 or 35 in a minute, occasioning, at the same time, vertigo, indistinct vision, violent and durable sickness, with vomiting. In a still larger quantity, it induces convulsions, coldness of the body, and insensibility; symptoms which have sometimes terminated fatally. As a narcotic, fox-glove has been recommended in epilepsy, insanity, and in some acute inflammatory diseases. Lately it has been very extensively employed in phthisis, and the beneficial effects which it produces in that disease, are probably owing to its narcotic power, by which it reduces the force of the circulation through the lungs and general system. It is administered so as to produce this effect. One grain of the powdered leaves, or ten drops of the saturated tincture, may be given night and morning. This dose is increased one half every second day, till its action on the system becomes apparent. As soon as the pulse begins to be diminished, the increase of dose must be made with more caution; and, whenever nausea is induced, it ought rather to be reduced, or, if necessary, intermitted for a short time. If the sickness become urgent, it is best relieved by stimulants, particularly large doses of brandy, with aromatics. The tincture has been supposed to be the best form of administering digitalis, when the remedy is designed to act as a narcotic: it is also more manageable in its dose, and more uniform in its strength, than the dried leaves.

Besides its narcotic effects, digitalis acts as one of the most certain diuretics in dropsy, apparently from its power of promoting absorption. It has frequently succeeded where the other diuretics have failed. Dr. Withering has an undoubted claim to this discovery; and the numerous cases of dropsy related by him, and other practitioners of established reputation, afford incontestible evidence of its diuretic powers, and of its practical importance in the cure of those disorders. From Dr. Withering's extensive experience of the use of the digitalis in dropsies, he has been able to judge of its success by the following circumstances: — "It seldom succeeds in men of great natural strength, of tense fibre, of warm skin, of florid complexion, or in those with a tight and cordy pulse. If the belly in ascites be tense, hard, and circumscribed, or the limbs in anasarca solid and resisting, we have but little hope. On the contrary, if the pulse be feeble, or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, the anasarcous limbs readily pitting under the pressure of the finger, we may expect the diuretic effects to follow in a kindly manner." Of the inferences which he deduces, the fourth is, "that if it (digitalis) fails, there is but little chance of any other medicine succeeding." Although the digitalis is now generally admitted to be a very powerful diuretic, yet it is but justice to acknowledge that this medicine has more frequently failed than could have been reasonably expected from a comparison of the facts stated by Dr. Withering. The dose of the dried leaves in powder, is from one to three grains twice a day. But if a liquid medicine be preferred, a drachm of the dried leaves is to be infused for four hours, in half a pint of boiling water, adding to the strained liquor an ounce of any spirituous water. One ounce of this infusion, given twice a day, is a medium dose. It is to be continued in these doses till it either acts upon the kidneys, the stomach, the pulse, (which, as has been said, it has a remarkable power of lowering,) or the bowels.

The administration of this remedy requires to be conducted with much caution. Its effects do not immediately appear; and when the doses are too frequent, or too quickly augmented, its action is concentrated so as to produce frequently the most violent symptoms. The general rules are, to begin with a small dose, to increase it gradually, till the action is apparent on the kidneys, stomach, intestines, or vascular system; and immediately suspending its exhibition, when its effects on any of these parts take place.

The symptoms arising from too large a dose of digitalis are, extreme sickness, vertigo, indistinct vision, incessant vomiting, and a great reduction of the force of the circulation, terminating sometimes in syncope, or convulsions. They are relieved by frequent and small doses of opium, brandy, aromatics, and strong bitters, and by a blister applied to the region of the stomach.

Digi'tium. (From *digitus*, a finger.) A contraction of the finger-joint. A paronychia, or whitlow, or other sore, upon the finger.

DI'GITUS. (From *digero*, to direct.) A finger.

Di'gitus ma'nus. A finger. The *fingers* and thumb in each hand consist of fourteen bones, there being three to each *finger*, and two to the thumb; they are a little convex and round towards the back of the hand, but hollow and plain towards the palm, except the last, where the nails are. The order of their disposition is called first, second, and third *phalanx*. The first is longer than the second, and the second longer than the third. What has been said of the fingers, applies to the toes also.

Di'gitus pe'dis. A toe. See *Digitus manus*.

Diglo'ssum. (From δις, double, and γλωσσα, a tongue; so called because above its leaf there grows a lesser leaf, like two tongues.) The laurus Alexandrina. Galen speaks of a man born with two tongues.

Digno'tio. (From *dignosco*, to distinguish.) See *Diagnosis*.

Dihæ'maton. (From δια, and αιμα, blood.) An antidote in which is the blood of many animals.

Diha'lon. (From δια, and αλς, salt.) A plaster prepared with salt and nitre, adapted to foul ulcers.

Dii'petes. (From Ζευς, διος, Heaven, and ϖιπτω, to fall: *i. e.* falling as rain.) An epithet applied by Hippocrates to semen, when it is discharged like a sudden shower of rain.

Dilata'tio. (From *dilato*, to enlarge.) Dilatation, or enlargement. Diastole.

DILA'TOR. (From *dilato*, to enlarge.) The name of some muscles whose office is to open and enlarge parts.

Dilato'res ala'rum na'si. See *Levator labii superioris*.

Dilato'rium. (From *dilato*, to enlarge.) A surgical instrument for enlarging any part. A speculum oris.

Dill. See *Anethum*.

DILUENTS. (*Diluentia*, sc. *medicamenta*; from *diluo*, to wash away.) Those substances which increase the proportion of fluid in the blood. It is evident that this must be done by watery liquors. Water is, indeed, properly speaking, the only diluent. Various additions are made to it, to render it pleasant, and frequently to give it a slightly demulcent quality. But these are not sufficiently important to require to be noticed, or to be classed as medicines.

Diluents are merely secondary remedies. They are given in acute inflammatory diseases, to lessen the stimulant quality of the blood. They are used to promote the action of diuretics in dropsy, and to favour the operation of sweating.

Di'nica. (From δινος, giddiness.) Medicines which relieve a giddiness.

Di'nos. (From δινεω, to turn round.) A vertigo, or giddiness.

Dio'cres. The name of a lozenge.

Di'odos. (From δια, and οδος, the way through.) Evacuation by stool.

Diœna'nthes. (From δια, and οινανθη, the flower of the vine.) A remedy said to be good for cholera, in which was the flower of the vine-tree.

Dio'gmus. (From διωκω, to persecute.) A distressing palpitation of the heart.

DIONIS, Peter, was born about the middle of the 17th century, and educated to the practice of surgery. He was appointed to read the lectures in anatomy, &c. in the royal gardens at Paris, instituted by Lewis XIV., and after this, surgeon to the queen, and other branches of the royal family, which offices he held, with great credit, to his death in 1718. His first publication gave an account of a woman who died in the sixth month of pregnancy, of what he considered to be a ruptured uterus: but as he states that there were two uteri, it is suspected that the ruptured part was one of the fallopian tubes much enlarged. He afterwards gave a useful epitome of anatomy, which was very favourably received, passed through several editions, and was even translated into the Tartar language, by order of the Emperor of China. His next work, a course of surgical operations, obtained still more celebrity, which it even now in some degree retains, especially as commented upon by Heister. Besides these, a dissertation on sudden death, and a treatise on midwifery, were published by this author.

Dionysi'scus. (From *Διονυσος*, Bacchus, who was of old represented as having horns.) Certain bony excrescences, near the temples, were called dionysisci.

Dionysony'mphas. (From *Διονύσος*, Bacchus, and *νυμφα*, a nymph.) A herb which, if bruised, smells of wine, and yet resists drunkenness.

Diopo'rum. (From *δια*, and *οπωρα*, autumnal fruits.) A medicine composed of ripe fruits for quincy.

Dio'ptra. (From *διοπτομαι*, to see through.) *Dioptron*. Speculum ani, oris, or uteri. Also the lapis specularis.

Dio'ptrica. (From *διοπτομαι*, to see through.) Dioptrics, or doctrine of the refraction of light.

Dioptri'smus. (From *διοπτομαι*, to see through.) Dilatation of any natural passage.

Dio'robum. (From *δια*, and *οροβος*, a vetch.) A medicine, in the composition of which there are vetches.

Diorrho'sis. (From *δια*, and *ορρος*, the serum.) *Diorosis*. A dissolved state of the blood. A conversion of the humours into serum and water.

Diorthro'sis. (From *διορθροω*, to direct.) The reduction of a fracture.

DIOSCO'REA. (Named in honour of Dioscorides.)

1. The name of a genus of plants in the Linnæan system. Class, *Diœcia*. Order, *Hexandria*.

2. An esculent root, called the yam, is obtained principally from three species of *Dioscorea*, the *alata*, *bulbifera*, and *sativa*. They grow spontaneously in both Indies, and their roots are promiscuously eaten as the potatoe is with us. There is great variety in the colour, size, and shape of yams; some are generally blue or brown, round or oblong, and weigh from one pound to two. They are esteemed when dressed as being nutritious and easy of digestion, and are preferred to wheaten bread. Their taste is somewhat like the potatoe, but more luscious. The negroes, whose common food is yams, boil and mash them. They are also ground into flour, and made into bread and puddings.

When they are to be kept for some time, they are exposed upon the ground to the sun, as we do onions, and when sufficiently withered, they are put into dry sand in casks, and placed in a dry garret, where they remain often for many seasons without losing any of their primitive goodness.

Diosco'rea ala'ta. See *Dioscorea*.

Diosco'rea bulbi'fera. See *Dioscorea*.

Diosco'rea sati'va. See *Dioscorea*.

DIOSCO'RIDES, Pedacius, or Pedanius, a celebrated Greek physician and botanist of Anazarba, in Cilicia, now Caramania, who is supposed to have lived in the time of Nero. He is said to have been originally a soldier, but soon became eminent as a physician, and travelled much to improve his knowledge. He paid particular attention to the materia medica, and especially to botany, as subservient to medicine. He profited much by the writings of Theophrastus, who appears to have been a more philosophical botanist. Dioscorides has left a treatise on the materia medica, in five books, chiefly considering plants; also two books on the composition and application of medicines, an essay on antidotes, and another on venomous animals. His works have been often printed in modern times, and commented upon, especially by Matthiolus. He notices about 600 plants, but his descriptions are often so slight and superficial, as to leave their identity a matter of conjecture; which is perhaps of no very great medical importance; though their virtues being generally handed down from the Greeks, it might be useful to ascertain which particular plants they meant.

Dioscu'ri. (*i. e.* *Διος*, *Κουροι*, the sons of Jupiter, or Castor and Pollux.) The parotids were so named from their twin-like equality in shape and position.

Diospy'ros lo'tus. *Indian date plum*. The fruit, when ripe, has an agreeable taste, and is very nutritious.

Dioxelæ'um. (From *δια*, *οξυς*, acid, and *ελαιον*, oil.) A medicine composed of oil and vinegar.

Dio'xos. (From *δια*, and *οξυς*, acid.) A collyrium composed chiefly of vinegar.

Diplasia'smus. (From *διπλοω*, to double.) The re-exacerbation of a disease.

DI'PLOE. (From *διπλοω*, to double.) *Meditullium*. The spongy substance between the two tables of the skull.

DIPLO'PIA. (From *διπλοος*, double, and *οπτομαι*, to see.) *Visus duplicatus*. A disease of the eye, in which the person sees an object double or triple. Dr. Cullen makes it a variety of the second species of pseudoblepsis, which he calls mutans, in which objects appear changed from what they really are: and the disease varies according to the variety of the remote cause.

Di'pnous. (From *δις*, twice, and *πνεω*, to breathe.) An epithet for wounds which are perforated quite through, and admit the air at both ends.

DI'PSACUS. (From *διψα*, thirst.) *Dipsacum*.

1. The name of a genus of plants in the Linnæan system, so called from the concave situation of its leaves, which hold water, by which the thirst of the traveller may be relieved. Class, *Syngenesia*. Order, *Polygamia*. The teasel.

2. A diabetes, from the continual thirst attending it.

Dipyre′num. (From δις, twice, and πυρην, a berry.) A berry, or kernel; a probe with two buttons.

Dipyri′tes. (From δις, twice, and πυρ, fire.) *Dipyros*. An epithet given by Hippocrates to bread twice baked, and which he recommended in dropsies.

DIRE′CTOR. (From *dirigo*, to direct.) A hollow instrument for guiding an incisor-knife; also the name of a muscle which lifts up the penis.

Directo′res pe′nis. (From *dirigo*, to direct.) The same as erectores penis.

Diri′nga. A name, in the isle of Java, for the calamus aromaticus.

Disce′ssus. (From *discedo*, to depart.) The separation of any two bodies, before united, by chemical operation.

Discifo′rmis. (From *discus*, a quoit, and *forma*, likeness.) Resembling a disk, or quoit, in shape. It is applied to the knee-pan.

Discoi′des. (From δισκος, a quoit.) Resembling a disk, or quoit, in shape. It is applied to the chrystalline humour of the eye.

Discri′men. A small roller. A term applied to the diaphragm.

DISCU′TIENTS. (*Discutientia*, sc. *medicamenta*; from *discutio*, to shake in pieces.) *Discusoria*. *Diachytica*. A term in surgery applied to those substances which possess a power of repelling or resolving tumours.

DISEASE. *Morbus*. Any alteration from a perfect state of health is a disease. A disease is variously termed: when it pervades the whole system, as an inflammatory fever, it is called a *general disease*, to distinguish it from inflammation of the eye, or any other viscus, which is a *partial* or *local* one: and when it does not depend on another disease, it is termed an *idiopathic disease*, (which may be either general or partial,) to distinguish it from a *symptomatic affection*, which depends upon another disease, and is produced by consent of parts. See also *Endemic*, *Epidemic*, *Sporadic*, &c.

DISLOCA′TION. (From *disloco*, to put out of place.) Luxation. The secession of a bone of a moveable articulation from its natural cavity.

DISPE′NSARY. (*Dispensarium*, from *dispendo*, to distribute.) The shop, or place, in which medicines are prepared. Also the name of an institution, in which the poor are supplied with medicines and advice.

DISPE′NSATORY. (*Dispensatorium*; from *dispendo*, to distribute.) *Antidotarium*. A book which treats of the composition of medicines.

DISSE′CTION. (From *disseco*, to cut asunder.) The cutting to pieces of any part of an animal, or vegetable, for the purpose of examining its structure.

Disse′ptum. (From *dissepio*, to inclose round.) The diaphragm, or membrane, which divides the cavity of the thorax from the abdomen.

Dissolve′ntia. (From *dissolvo*, to loosen.) Medicines which loosen and dissolve morbid concretions in the body. In chemistry, it means menstrua.

Dissolu′tus. (From *dissolvo*, to loosen.) Loose. An epithet applied to the dysentery, or morbus dissolutus.

Diste′ntio. (From *distendo*, to stretch out.) Distention, or dilatation. A convulsion.

Disti′chia. See *Distichiasis*.

DISTICHI′ASIS. (From διστιχια: from δις, double, and ϛιχος, a row.) *Districhiasis*. *Distichia*. A disease of the eyelash, in which there is a double row of hairs, the one row growing outwards, the other inwards towards the eye.

DISTILLA′TION. (From *distillo*, to drop little by little.) *Alsacta*. *Catastagmos*. A chemical process, very similar to evaporation, instituted to separate the volatile from the fixed principles, by means of heat. Distillatory vessels are either alembics or retorts; the former consist of an inferior vessel, called a cucurbit, designed to contain the matter to be examined, and having an upper part fixed to it, called the capital, or head. In this last, the vapours are condensed by the contact of the surrounding air, or, in other cases, by the assistance of cold water surrounding the head, and contained in a vessel called the refrigeratory. From the lower part of the capital proceeds a tube, called the nose, beak, or spout, through which the vapours, after condensation, are, by a proper figure of the capital, made to flow into a vessel called the receiver, which is usually spherical. These receivers have different names, according to their figure, being called mattrasses, balloons, &c. Retorts are a kind of bottle of glass, pottery, or metal, the bottom being spherical, and the upper part gradually diminishing into a neck, which is turned on one side.

DISTO′RTION. (From *distorqueo*, to wrest aside.) *Distortio*. A term applied to the eyes, when a person seems to turn them from the object he would look at, and is then called squinting, or strabismus. It also signifies the bending of a bone preternaturally to one side; as distortion of the spine, or vertebræ.

Disto′rtor. (From *distorqueo*, to wrest aside.) A muscle, whose office is to draw the mouth awry.

Disto′rtor o′ris. (From *distorqueo*, to wrest aside.) The zygomaticus minor.

Districhi′asis. See *Distichiasis.*

Di′strix. (From δις, double, and θριξ, the hair.) A disease of the hair, when it splits and divides at the end.

Dittander. See *Lepidium sativum.*

Dittany, bastard. See *Dictamnus albus.*

Dittany of Crete. See *Origanum dictamnus.*

Dittany, white. See *Dictamnus albus.*

DIURE′SIS. (From δια, through, and ουρεω, to make water.) An increased secretion of urine. It is also applied to a diabetes.

DIURETICS. (*Diuretica,* sc. *medicamenta,* διουρητικα: from διουρησις, a discharge of urine.) Those medicines or substances are so called which, when taken internally, augment the flow of urine from the kidneys. It is obvious that such an effect will be produced by any substance capable of stimulating the secreting vessels of the kidneys. All the saline diuretics seem to act in this manner. They are received into the circulation; and, passing off with the urine, stimulate the vessels, and increase the quantity secreted.

There are other diuretics, the effect of which appears not to arise from direct application, but from an action excited in the stomach, and propagated by nervous communication to the secreting urinary vessels.

The diuretic operation of squill, and several other vegetables, appears to be of this kind.

There is still, perhaps, another mode in which certain substances produce a diuretic effect; that is, by promoting absorption. When a large quantity of watery fluid is introduced into the circulating mass, it stimulates the secreting vessels of the kidneys, and is carried off by urine. If, therefore, absorption be promoted, and if a portion of serous fluid, perhaps previously effused, be taken up, the quantity of fluid secreted by the kidneys will be increased. In this way digitalis seems to act: its diuretic effect, it has been said, is greater when exhibited in dropsy than it is in health.

On the same principle, (the effect arising from stimulating the absorbent system,) may probably be explained the utility of mercury in promoting the action of several diuretics.

The action of these remedies is promoted by drinking freely of mild diluents. It is also influenced by the state of the surface of the body. If external heat be applied, diuresis is frequently prevented, and diaphoresis produced. Hence the doses of them should be given in the course of the day, and the patient, if possible, be kept out of bed.

The direct effects of diuretics are sufficiently evident. They discharge the watery part of the blood; and, by that discharge, they indirectly promote absorption over the whole system.

Dropsy is the disease in which they are principally employed; and when they can be brought to act, the disease is removed with less injury to the patient than it can be by exciting any other evacuation. Their success is very precarious, the most powerful often failing; and, as the disease is so frequently connected with organic affection, even the removal of the effused fluid, when it takes place, only palliates without effecting a cure.

Diuretics have been likewise occasionally used in calculous affections, in gonorrhœa, and with a view of diminishing plethora, or checking profuse perspiration.

Murray, in his Elements of Materia Medica, classes the super-tartrate of potash, or cream of tartar, and nitrate of potash, or nitre, the muriate of ammonia, or crude sal ammoniac, potash, and the acetate of potash, or kali acetatum, among the *saline* diuretics; and selects the following from the *vegetable* kingdom: — scilla maritima, digitalis purpurea, nicotiana tabacum, solanum dulcamara, lactuca virosa, colchicum autumnale, gratiola officinalis, spartium scoparium, juniperus communis, copaifera officinalis, pinus balsamea, and pinus larix; and the lytta vesicatoria from the *animal* kingdom.

In speaking of particular diuretics, Dr. Cullen says, the diuretic vegetables mentioned by writers are of very little power, and are employed with very little success. Of the umbellatæ, the medicinal power resides especially in their seeds; but he never found any of them very efficacious. The semen dauci sylvestris has been commended as a diuretic; but its powers as such are not very remarkable. In like manner some of the *plantæ stellatæ* have been commended as diuretics; but none of them deserve our notice, except the *rubia tinctorium,* the root of which passes so much by the kidneys as to give its colour to the urine. Hence it may fairly be supposed to stimulate the secretories; but Dr. Cullen found its diuretic powers did not always appear, and never to any considerable degree; and as, in brute animals, it has always appeared hurtful to the system, he does not think it fit to be employed to any extent in human diseases. The bardana, lithospermum, ononis, asparagus, enula campana, are all substances which seem to pass, in some measure, by the kidneys; but their diuretic powers are hardly worth notice.

The principal articles included by Dr. Cullen, in his catalogue of diuretics, are dulcamara, digitalis, scilla; some of the alliaceæ and siliquosæ; the balsams and resins; cantharides, and the diuretic salts.

Divapora′tio. Evaporation.

Divarication. The crossing of any two things: thus when the muscular or tendinous fibres intersect each other at different angles, they are said to divaricate.

Diverso′rium. (From *diversor,* to resort to.) The receptaculum chyli.

DIVERTI'CULUM. A mal-formation or diseased appearance of a part, in which a portion goes out of the regular course; and thereby forms a diverticulum, or deviation from the usual course. It is generally applied to the alimentary canal.

Diverti'culum nu'ckii. The opening through which the round ligaments of the uterus pass. Nuck asserted that it remained open a long time after birth; to these openings he gave the name of *diverticula*.

Divi'nus. A pompous epithet of many compositions, from their supposed excellence.

Divu'lsio. (From *divello*, to pull asunder.) Urine with a ragged and uneven sediment.

Docimastic art. *Ars docimastica.* The art of examining fossils, in order to discover what metals, &c. they contain.

Dock-cresses. See *Lapsana.*

Dock, sour. See *Rumex acetosa.*

Dock, water. See *Rumex hydrolapathum.*

Dodder of thyme. See *Cuscuta epithymum.*

Dodecada'ctylus. (From δωδεκα, twelve, and δακτυλος, a finger; so named because its length is about the breadth of twelve fingers.) The duodenum, an intestine so called. It must be observed, that at the time this name was given anatomy consisted in the dissection of brutes; and the length was therefore probably adjudged from the gut of some animal, and not of man.

Dodecapha'rmacum. (From δωδεκα, twelve, and φαρμακον, a medicine.) An ointment consisting of twelve ingredients, for which reason it was called the ointment of the twelve apostles.

Dodeca'theon. (From δωδεκα, twelve, and τιθημι, to put.) An antidote consisting of twelve simples.

DODONÆUS, Rembertus, (or Dodoens,) was born at Mechlin in 1517. He became physician to two succeeding emperors, and in 1582 was appointed professor of physic in the newly-founded University of Leyden; the duties of which he performed with credit till his death three years after. His fame at present chiefly rests on his botanical publications, particularly his "Pemptades," or 30 books of the history of plants. The "Frugum Historia," "Herbarium Belgicum," &c. are of much inferior merit.

Dog-rose. See *Rosa canina.*

Dog's bane, Syrian. This plant, *Asclepias Syriaca* of Linnæus, is particularly poisonous to dogs, and also to the human species. Boiling appears to destroy the poison in the young shoots, which are then said to be esculent, and flavoured like asparagus.

Dog's-grass. See *Triticum repens.*

Dog's-mercury. See *Mercurialis perennis.*

Dog-stones. See *Orchis mascula.*

DO'GMA. (From δοκεω, to be of opinion.) An opinion founded on reason and experience.

DO'LICHOS. (From δολιχος, long: so called from its long shape.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia.* Order, *Decandria.*

2. The pharmacopœial name of the cowhage. See *Dolichos pruriens.*

Do'lichos so'ja. The plant which affords the soy. It is much cultivated in Japan, where it is called *daidsu:* and where the pods supply their kitchens with various productions; but the two principal are, a sort of butter, termed *miso*, and a pickle called *sooju.*

Do'lichos pru'riens. The systematic name of the cowhage. *Dolichos. Dolichos pruriens; volubilis, leguminibus racemosis, valvulis subcarinatis hirtis, pedunculis ternis,* of Linnæus. The pods of this plant are covered with sharp hairs, which are the parts employed medicinally in form of electuary, as anthelmintics. The manner in which these hairy spicula act, seems to be purely mechanical: for neither the tincture, nor the decoction, possess the least anthelmintic power.

Do'lor facie'i. See *Tic douloureux.*

DORO'NICUM. (From *dorongi*, Arab.) Leopard's bane. See *Arnica.*

Doro'nicum germa'nicum. See *Arnica.*

Doro'nicum pardalia'nches. The systematic name of the Roman leopard's bane. See *Doronicum romanum.*

Doro'nicum roma'num. Roman leopard's bane. *Doronicum pardalianches; foliis cordatis, obtusis, denticulatis; radicalibus petiolatis; caulinis amplexicaulibus,* of Linnæus. The root of this plant, if given in a full dose, possesses poisonous properties; but instances are related of its efficacy in epileptical and other nervous diseases.

DO'RSAL. Belonging to the back.

Dorsa'les ne'rvi. The nerves which pass out from the vertebræ of the back.

Do'rsi spina'lis. See *Spinalis dorsi.*

DORSTE'NIA. (Named in honour of Dr. Dorsten.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria.* Order, *Monogynia.*

Dorste'nia contraye'rva. The systematic name of the plant which affords the contrayerva root. *Contrayerva. Drakena. Cyperus longus, odorus, peruanus. Bezoardica radix.*

The contrayerva was first brought into Europe about the year 1581, by Sir Francis Drake, whence its name Drakena. It is the root of a small plant found in Peru, and other parts of the Spanish West Indies. Dr. Houston observes, that the roots of different species of dorstenia are promiscuously gathered and exported for those of the contrayerva, and, as all the species bear a great resemblance to each other, they are generally used for medical purposes in this country. The tuberous parts of these roots are the strongest, and should be chosen for use. They have an agreeable aromatic smell; a rough bitter, penetrating taste; and when chewed, they give out a sweetish kind of acrimony.

It is diaphoretic and antiseptic; formerly used in low nervous fevers, and those of the malignant kind; though taken freely, it does not produce much heat. It is, however, now seldom used, though, with the Peruvian bark in decoction, it is occasionally employed in ulcerated sore throats, as a gargle.

Dr. Cullen observes, that this and serpentaria are powerful stimulants; and both have been employed in fevers in which debility prevailed. However, he thinks, wine may always supersede the stimulant powers of these medicines; and that debility is better remedied by the tonic and antiseptic powers of cold and Peruvian bark, than by any stimulants.

By the assistance of heat, both spirit and water extract all its virtues; but they carry little or nothing in distillation; extracts made by inspissating the decoction, retain all the virtues of the root.

The London College forms the compound powder of contrayerva by combining five ounces of contrayerva root with a pound and a half of prepared shells. This powder was formerly made up in balls, and called *lapis contrayervæ*, employed in the decline of ardent fevers, and through the whole course of low and nervous ones. The radix serpentariæ virginiensis, in all cases, may be substituted for the contrayerva.

Dorste'nia Drake'na. The systematic name for one sort of the contrayerva.

Dorste'nia Housto'nii. See *Dorstenia contrayerva*.

Do'thien. A name for the furunculus.

Dove'ri pu'lvis. See *Pulvis ipecacuanhæ compositus*.

Dove's foot. The geranium columbinum.

DOUGLAS, James, M. D. was born in Scotland in 1675. After completing his education, he came to London, and applied himself diligently to the study of anatomy and surgery, which he both taught and practised several years with success. Haller has spoken very highly of his preparations, to shew the motion of the joints, and the structure of the bones. He patronized the celebrated William Hunter; who assisted him shortly before his death in 1742. He was reader of Anatomy to the Company of Surgeons, and a Fellow of the Royal Society, to which he made several communications. He published, in 1707, a more correct description of the muscles than had before appeared; eight years after, a tolerable account of preceding anatomical writers; in 1726, a History of the lateral Operation for the Stone; and in 1730, a very accurate Description of the Peritoneum, &c.

DOUGLAS, John, brother of the preceding, was surgeon to the Westminster Infirmary, and author of several controversial pieces. In one of them, called "Remarks on a late pompous Work," he censures, with no small degree of severity, Cheselden's Anatomy of the Bones; in another, he criticises, with equal asperity, the works of Chamberlen and Chapman; and in a third, he decries the new forceps of Dr. Smellie. He also wrote a work on the high operation for the stone, which he practised; a Dissertation on the Venereal Disease; and an Account of the Efficacy of Bark in stopping gangrene.

DRA'BA. (From δρασσω, to seize; so called from its sudden effect upon the nose of those who eat it.)

1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*. Order, *Siliculosa*.

2. A name of the lepidium, or Arabian mustard, and Turkey cresses.

Dra'co sylve'stris. See *Achillea Ptarmica*.

DRACOCE'PHALUM. (From δρακων, a dragon, and κεφαλη, a head.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*. Order, *Gymnospermia*.

Dracoce'phalum canarie'nse. The systematic name of the balm of Gilead. *Moldavica*. *Melissa Turcica*. Turkey-balsam. Canary balsam. Balsam of Gilead. This plant, *Dracocephalum moldavica; floribus verticellatis, bracteis lanceolatis, serraturis capillaceis* of Linnæus, affords a fragrant essential oil, by distillation, known in Germany by the name of *oleum syriæ*. The whole herb abounds with an aromatic smell, and an agreeable taste, joined with an aromatic flavour; it is recommended to give tone to the stomach and nervous system.

Draco'nis sa'nguis. See *Calamus rotang*.

Draco'ntium. (From δρακων, a dragon; so called because its roots resemble a dragon's tail.) See *Arum dracunculus*.

DRACU'NCULUS. (From δρακων, a serpent.) The Guinea worm; called also vermiculus capillaris. These animalcules are common in both Indies, in most parts of Africa, occasionally at Genoa, and other hot countries. These worms resemble the common worm, but are much larger; commonly found in the legs, but sometimes in the muscular part of the arms. They principally affect children, and their generation is not unlike that of the broad worms of the belly; hence their name tape-worm. While they move under the skin, they create no trouble; but, in length of time, the place near the dracunculus suppurates, and the animal puts forth its head. If it be drawn, it excites considerable uneasiness, especially if drawn so forcibly as to break it; for the part left within creates intolerable pain.

These worms are of different lengths. In the Edin. Med. Essays, mention is made of one that was three yards and a half in length.

Dragaca′ntha. See *Astragalus*.

Dragant gum. See *Astragalus*.

Dragon's blood. See Calamus *rotang*.

Dragon's wort. See *Arum dracunculus*.

DRAKE, James, M.D. Fellow of the College of Physicians, and of the Royal Society, published, in 1707, "A new System of Anatomy;" which, though taken principally from Cowper, being on a reduced plan, and more within the reach of students, was pretty favourably received. In the third edition, it was styled "Anthropologia Nova." In abscesses of the antrum maxillare, he advised drawing one of the molar teeth, to let out the matter. The description of the internal nostrils, and of the cavities entering them, is new; as are also the plates of the abdominal viscera.

Drake′na. See *Dorstenia contrayerva*.

DRA′STICA. (*Drastica*, sc. *medicamenta*, δραστικος, active, brisk; from δραω, to effect.) A term generally applied to those medicines which are very violent in their action; thus, drastic purges, emetics, &c.

DRELINCOURT, Charles, was born at Paris in 1633; and after studying some years at Saumur, he went to graduate at Montpelier. He soon after attended the celebrated Turenne in his campaigns, and was by him made physician to the army. He was also appointed one of the physicians to Lewis XIV. But in 1688 he was chosen to succeed Vander Linden, as professor of medicine at Leyden; and two years after he was advanced to the chair of anatomy. He was also made physician to William, then Prince of Orange, and his consort; and on their accession to the throne of England, he spoke the congratulatory oration to them, as rector of the university. He continued in his professorship, giving general satisfaction to the period of his death in 1697. He was a voluminous and learned, but hardly an original writer; yet his works were very much read at the time. In one of his orations, he exculpates medical men from the charge of impiety, observing that the contemplation of the works of God tends to bind them more to religion. In his "Apologia Medica," he refutes the notion, that physicians were excluded from Rome for six hundred years. He strenuously opposed the introduction of chemical preparations into medicine, which was then very prevalent. His son, *Charles*, succeeded him in practice, but has left no publication, except his thesis "De Lienosis."

Dresde′nsis pu′lvis. An oleo saccharum, containing the oil of cinnamon.

Dro′ma. The name of a plaster described by Myrepsus.

Dropaci′smus. (From δρεπω, to remove.) *Dropax*. A stimulant plaster of pitch, wax, &c. to take off hair.

Dro′pax. See *Dropacismus*.

DRO′PSY. A collection of a serous fluid in the cellular membrane; in the viscera and the circumscribed cavities of the body. See *Hydrops*. *Ascites*, *Anasarca*, *Hydrocephalus*, *Hydrothorax*, *Hydrocele*.

Dropsy of the belly. See *Ascites*.

Dropsy of the brain. See *Hydrocephalus*.

Dropsy of the cellular membrane. See *Anasarca*.

Dropsy of the chest. See *Hydrothorax*.

Dropsy of the ovaria. See *Ascites*.

Dropsy of the testicle. See *Hydrocele*.

Dropwort. See *Œnanthe*, and *Spiræa Filipendula*.

Dropwort hemlock. See *Œnanthe*.

Dropwort water. See *Œnanthe*.

DRO′SERA. (From δροσερα, dewy; which is from δροσος, dew; drops hanging on the leaves like dew.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Hexagynia*. Sundew.

Dro′sera rotundifo′lia. The systematic name of the sun-dew. *Ros solis*. *Rorella*. Sun-dew. This elegant little plant, *Drosera rotundifolia*; *scapis radicatis*; *foliis orbiculatis* of Linnæus, is said to be so acrid as to ulcerate the skin, and remove warts and corns; and to excite a fatal coughing and delirium in sheep who eat it. It is seldom given medicinally in this country but by the lower orders, who esteem a decoction of it as serviceable in asthmas and coughs.

Drosiobo′tanum. (From δροσος, dew, and βοτανη, a herb; so called from its being covered with an aromatic dew.) The herb betony. See *Betonica*.

Drosso′meli. (From δροσος, dew, and μελι, honey.) Honey-dew. Manna.

Dry belly-ach. See *Colica*.

DUCTI′LITY. A property by which bodies are elongated by repeated or continued pressure. It is peculiar to metals.

Ducts, biliary. See *Biliary duct*.

DU′CTUS ARTERIO′SUS. A great inosculation found only in the fœtus, and very young children, betwixt the pulmonary artery and the aorta. In adults it is closed up.

DU′CTUS AD NA′SUM. See *Canalis nasalis*.

Du′ctus au′ris palati′nus. The eustachian tube.

Du′ctus bilia′ris. See *Choledochus ductus*.

DU′CTUS COMMU′NIS CHOLE′DOCHUS. See *Choledochus ductus*.

DU′CTUS HEPA′TICUS. See *Hepatic duct*.

DU′CTUS LACHRYMA′LIS. See *Lachrymal ducts*.

DU′CTUS LACTI′FERI. *Ductus galactophori*. The excretory ducts of the glandular substance composing the female breast. The milk passes along these ducts to the nipple.

DU'CTUS PANCREA'TICUS. The pancreatic duct. It is white and small, and arises from the sharp extremity of the pancreas, runs through the middle of the gland towards the duodenum, into which it pours its contents by an opening common to it and the *ductus communis choledochus*.

DU'CTUS SALIVA'LES. The excretory ducts of the salivary glands, which convey the saliva into the mouth.

DU'CTUS STENO'NIS. The Stenonian duct, which was so called after its discoverer, *Steno*. It arises from all the small excretory ducts of the parotid gland, and passes transversely over the masseter muscle, penetrates the buccinator, and opens into the mouth.

DU'CTUS THORA'CICUS. See *Thoracic duct*.

DU'CTUS VENO'SUS. When the vena cava passes the liver in the fœtus, it sends off the ductus venosus, which communicates with the sinus of the vena portæ; but, in adults, it becomes a flat ligament.

DU'CTUS WARTHONIA'NUS. The excretory duct of the maxillary glands; so named after its discoverer.

Dulca'cidum. (From *dulcis*, sweet, and *acidus*, sour.) An oxymel. A medicine composed of a sweet and sour ingredient.

DULCAMA'RA. (From *dulcis*, sweet, and *amarus*, bitter.) See *Solanum dulcamara*.

DUNCAN, Daniel, was born at Montauban, in Languedoc, in 1649, son of a professor of physic in that city, but of a family originally Scotch. Having lost both his parents in early infancy, he was taken under the protection of his maternal uncle, and at a proper age sent to study medicine at Montpelier, where he took his degree. He afterwards resided seven years at Paris, where he published his first work, upon the principle of motion in animal bodies. He then visited London, partly to arrange some family affairs, partly to obtain information concerning the plague; and intended to have settled there: but after two years he was summoned to attend his patron, the great Colbert. He soon after made public two works, in which he attempted to explain the Animal Functions on Chemical and Mechanical Principles. On the death of Colbert, he resided for some years in his native city, but the persecution of the Protestants in 1690 drove him to Swisserland; and he was appointed professor of Anatomy and Chemistry at Berne, where he got into considerable practice. In 1699 he was sent for to attend the Princess of Hesse-Cassel, who had symptoms of threatening consumption, induced by the excessive use of tea, and other hot liquors: which led him to write a Treatise against that practice, published subsequently by the persuasion of his friend, Boerhaave. He remained there three years, affording meanwhile much relief to the French refugees; and the fame of his liberality procured his invitation to the court of Berlin: but a regard to his health and to economy soon obliged him to remove to the Hague. In 1714 he accomplished his favourite object of settling in London, and when he reached his 70th year, put in practice his previous resolution of giving his professional services only gratuitously; in which he steadily persevered during the remaining sixteen years of his life, though in 1721 he lost the third part of his property by the South-sea scheme.

Dung, devil's. See *Ferula assafœtida*.

Duo. (Δυω, two.) Some compositions consisting of two ingredients, are distinguished by this term, as pilulæ ex duobus.

DUODE'NUM. (From *duodenus*, consisting of twelve; so called because it was supposed not to exceed the breadth of twelve fingers; but as the antients dissected only animals, this does not hold good in the human subject.) The first portion of the small intestines. See *Intestines*.

Duplica'na. (From *duplex*, double.) A name of the double tertian fever.

DU'RA MA'TER. (From *durus*, hard, and *mater*, a mother; called *dura*, from its comparative hardness with the *pia mater*, and *mater*, from its being supposed to be the source of all the other membranes.) *Dura meninx*. *Dermatodes*. A thick and somewhat opaque and insensible membrane, formed of two layers, that surrounds and defends the brain, and adheres strongly to the internal surface of the cranium. It has three considerable processes, the falciform, the tentorium, and the septum cerebelli; and several sinusses, of which the longitudinal, lateral, and inferior longitudinal, are the principal. Upon the external surface of the dura mater, there are little holes, from which emerge fleshy-coloured papillæ, and which, upon examining the skull-cap, will be found to have corresponding foveæ. These are the external glandulæ Pacchioni. They are in number from ten to fifteen on each side, and are chiefly lateral to the course of the longitudinal sinus. The arteries which supply this membrane with vessels for its own nourishment, for that of the contiguous bone, and for the perpetual exudation of the fluid, or halitus rather, which moistens or bedews its internal surface, may be divided into anterior, middle, and posterior. The first proceeds from the ophthalmic and ethmoidal branches; the second from the internal maxillary and superior pharyngeal; the posterior from the occipital and vertebral arteries.

The principal artery of the dura mater, named, by way of distinction, the great artery of the dura mater, is derived from the internal maxillary artery, a branch of the external carotid. It is called the spinalis, or spheno-spinalis, from its passing into the head through the spinous hole of the sphenoid bone, or meninga media, from its relative situation, as it rises in the great middle fossa of the skull. This artery, though it sometimes enters the skull in two branches, usually enters in one considerable branch, and divides, soon after it reaches the dura mater, into three or four branches, of which the anterior is the largest; and these spread their ramifications beautifully upon the dura mater, over all that part which is opposite to the anterior, middle, and posterior lobes of the brain. Its larger trunks run upon the internal surface of the parietal bone, and are sometimes for a considerable space buried in its substance. The extreme branches of this artery extend so as to inosculate with the anterior and posterior arteries of the dura mater; and through the bones, (chiefly parietal and temporal bones,) they inosculate with the temporal and occipital arteries. The meningeal artery has been known to become aneurismal, and distended at intervals; it has formed an aneurism, destroying the bones and causing epilepsy.

Du′ra me′ninx. Before the time of Galen, the term meninx was common to all the membranes of the body; afterwards it was appropriated to those of the brain. See *Dura mater*.

Dwale. See *Atropa belladonna.*

Dwarf, elder. See *Sambucus ebulus.*

Dyo′ta. (From δυω, two, and ους, ωτος, an ear.) A chemical instrument with two ears, or handles.

DYSÆSTHE′SIA. (From δυς, difficulty, and αισθανομαι, to feel or perceive.) Impaired feeling.

DYSÆSTHE′SIÆ. An order in the class, *locales* of Dr. Cullen's Nosology, containing those diseases, in which the senses are depraved, or destroyed, from a defect of the external organs.

Dysanago′gus. (From δυς, with difficulty, and αναγω, to subdue.) Viscid expectoration.

Dyscatapo′tia. (From δυς, and καταπινω, to drink.) A difficulty of swallowing liquids, which Dr. Mead thinks a more proper term than that generally used for canine madness, viz. hydrophobia; as it is more particularly descriptive of the affection under which the unhappy patients labour; for in reality, they dread water from the difficulty of swallowing it.

DYSCINE′SIA. (From δυς, bad, and κινεω, to move.) Bad or imperfect motion.

DYSCINE′SIÆ. An order in the class *locales* of Cullen's nosology; embracing diseases in which the motion is impeded, or depraved, from an imperfection of the organ.

Dyscopho′sis. (From δυς, with difficulty, and κωφοω, to be deaf.) A defect in the sense of hearing.

DYSCRA′SIA. (From δυς, with difficulty, and κεραννυμι, to mix.) A bad habit of body.

DYSECŒ′A. (From δυς, difficulty, and ακοη, hearing.) *Cophosis.* Deafness. Hearing diminished, or destroyed. A genus of disease in the class *locales*, and order *dysæsthesiæ* of Cullen, containing two species: *Dysecœa organica*, which arises from wax in the meatus, injuries of the membrane, or inflammation and obstruction of the tube: *Dysecœa atonica*, when without any discernible injury of the organ.

Dyse′lcia. (From δυς, with difficulty, and ελκος, an ulcer.) An ulcer difficult to heal.

Dyse′metus. (From δυς, with difficulty, and εμεω, to vomit.) A person not easily made to vomit.

Dysente′ria. See *Dysentery.*

DYSENTERY. (From δυς, difficulty, and εντερα, the bowels.) *Dysenteria. Dissolutus morbus. Diarrhœa carnosa.* The flux. A genus of disease in the class *pyrexiæ*, and order *profluvia* of Cullen's nosology. It is known by contagious pyrexia; frequent griping stools; tenesmus; stools, chiefly mucous, sometimes mixed with blood, the natural fæces being retained or voided in small, compact, hard substances, known by the name of scybala; loss of appetite, and nausea. It occurs chiefly in summer and autumn, and is often occasioned by much moisture succeeding quickly intense heat, or great drought; whereby the perspiration is suddenly checked, and a determination made to the intestines. It is likewise occasioned by the use of unwholesome and putrid food, and by noxious exhalations and vapours; hence it appears often in armies encamped in the neighbourhood of low marshy grounds, and proves highly destructive; but the cause which most usually gives rise to it, is a specific contagion; and when it once makes its appearance, where numbers of people are collected together, it not unfrequently spreads with great rapidity. A peculiar disposition in the atmosphere seems often to predispose, or give rise to the dysentery, in which case it prevails epidemically.

It frequently occurs about the same time with autumnal intermittent and remittent fevers, and with these it is often complicated.

The disease, however, is much more prevalent in warm climates than in cold ones; and in the months of August, September, and October, which is the rainy season of the year in the West Indies, it is very apt to break out and to become very general among the negroes on the different plantations in the colonies. The body having been rendered irritable by the great heat of the summer, and being exposed suddenly to much moisture with open pores, the blood is thereby thrown from the exterior vessels upon the interior, so as to give rise to dysenteries.

An attack of dysentery is sometimes preceded by loss of appetite, costiveness, flatulency, sickness at the stomach, and a slight vomiting, and comes on with slight chills, succeeded by heat in the skin, and frequency of the pulse. These symptoms are in general the forerunners of the griping and increased evacuations which afterwards occur.

When the inflammation begins to occupy the lower part of the intestinal tube, the stools become more frequent, and less abundant; and, in passing through the inflamed parts, they occasion great pain, so that every evacuation is preceded by a severe griping, as also a rumbling noise.

The motions vary both in colour and consistence, being sometimes composed of frothy mucus, streaked with blood, and at other times of an acrid watery humour, like the washings of meat, and with a very fetid smell. Sometimes pure blood is voided; now and then lumps of coagulated mucus, resembling bits of cheese, are to be observed in the evacuations, and in some instances a quantity of purulent matter is passed.

Sometimes what is voided consists merely of a mucous matter, without any appearance of blood, exhibiting that disease which is known by the name of dysenteria alba, or morbus mucosus.

Whilst the stools consist of these various matters, and are voided frequently, it is seldom that we can perceive any natural fæces among them, and when we do, they appear in small hard balls, called scybala, which being passed, the patient is sure to experience some temporary relief from the griping and tenesmus.

It frequently happens, from the violent efforts which are made to discharge the irritating matters, that a portion of the gut is forced beyond the verge of the anus, which, in the progress of the disease, proves a troublesome and distressing symptom; as does likewise the tenesmus, there being a constant inclination to go to stool, without the ability of voiding any thing, except perhaps a little mucus.

More or less pyrexia usually attends with the symptoms which have been described, throughout the whole of the disease, where it is inclined to terminate fatally; and is either of an inflammatory or putrid tendency. In other cases, the febrile state wholly disappears after a time, while the proper dysenteric symptoms probably will be of long continuance. Hence the distinction into acute and chronic dysentery.

When the symptoms run high, produce great loss of strength, and are accompanied with a putrid tendency and a fetid and involuntary discharge, the disease often terminates fatally in the course of a few days; but when they are more moderate, it is often protracted to a considerable length of time, and so goes off at last by a gentle perspiration, diffused equally over the whole body; the fever, thirst, and griping then ceasing, and the stools becoming of a natural colour and consistence. When the disease is of long standing, and has become habitual, it seldom admits of an easy cure; and when it attacks a person labouring under an advanced stage of scurvy, or pulmonary consumption, or whose constitution has been much impaired by any other disorder, it is sure to prove fatal. It sometimes appears at the same time with autumnal intermittent and remittent fevers, as has been observed, and is then more complicated and difficult to remove.

Upon opening the bodies of those who die of dysentery, the internal coat of the intestines (but more particularly of the colon and rectum) appears to be affected with inflammation and its consequences, such as ulceration, gangrene, and contractions. The peritonæum and other coverings of the abdomen, seem likewise, in many instances, to be affected by inflammation.

In the treatment of the acute dysentery, when not arising from contagion, but attended by considerable pyrexia and pain, in persons of a strong and full habit, it will be right to commence by a moderate venæsection; but in general leeches to the abdomen will abstract a sufficient quantity of blood, followed by fomentations, or the warm bath, which may produce a powerful determination to the surface as well as counteract spasm; also blisters or rubefacients should not be neglected. With regard to internal remedies, a brisk emetic will often be advisable, particularly where the tongue is very foul, the stomach loaded, or marks of congestion in the liver appear: it may also by inducing diaphoresis materially check the violence of the symptoms, nay sometimes cut short the disease at once. The next object is effectually to clear out the bowels: for which purpose calomel, joined with opium in quantity sufficient to relieve the pain may be given, and followed up by castor oil, neutral salts, &c. till they operate. In the mean time mucilaginous demulcents may help to moderate the irritation. When the bowels have been thoroughly evacuated, it will be important to procure a steady determination to the surface, and the compound powder of ipecacuanha is perhaps the best medicine; assisted by warm clothing, friction, exercise, &c. Should the liver not perform its office properly, the continued use of mercury may be necessary; to restore the strength, and relieve dyspeptic symptoms, tonics and antacids will be useful, with a mild nutritious diet; and great care must be taken to obviate accumulation of fæces. In the chronic form of the disease, demulcents and sedatives may be freely employed by the mouth or in the form of clyster; the bowels may be occasionally relieved by rhubarb, or other mild aperient; mercury should be cautiously employed, where the discharge of bile is indicated, or if that cannot be borne, nitric acid may be tried; and besides great attention to regimen, as in the decline of acute dysentery, mild astringents, with tonics, &c. may contribute materially to the recovery of the patient.

Dysepulo'ticus. (From δυς, with difficulty, and επυλοω, to cicatrize.) *Dysepulotus.* An inveterate ulcer difficult to be healed.

Dyshæmorrho'is. (From δυς, with difficulty, and αιμορροϊς, the piles.) Suppression of bleeding piles.

DYSLO'CHIA. (From δυς, difficultly, and λοχια, the lochia.) A suppression of the lochia.

DYSMENORRHÆ'A. (From δυς, with difficulty, and μηνορροια, the menses.) A difficult or painful menstruation, accompanied with severe pains in the back, loins, and bottom of the belly.

Dyso'des. (From δυς, bad, and οζω, to smell.) A bad smell. Fœtid. Hippocrates applies it to a fœtid disorder of the small intestines. Also the name of a malagma and acopon in Galen and Paulus Ægineta.

DYSO'PIA. (From δυς, bad, and ωψ, an eye.) *Parorasis.* Difficult sight. Sight depraved, requiring one certain quantity of light, one particular distance, or one position. A genus of disease in the class *locales*, and order *dysæsthesiæ* of Cullen, containing the five following species: 1. *Dysopia tenebrarum,* called also *amblyopia crepuscularis,* requiring objects to be placed in a strong light. 2. *Dysopia luminis,* likewise termed *amblyopia meridiana,* objects only discernible in a weak light. 3. *Dysopia dissitorum,* in which distant objects are not perceived. 4. *Dysopia proximorum,* or *dysopia amblyopia,* in which objects too near are not perceived. 5. *Dysopia lateralis,* called also *amblyopia luscorum,* in which objects are not seen, unless placed in an oblique position.

DYSORE'XIA. (From δυς, bad, and ορεξις, appetite.) A bad or depraved appetite.

DYSORE'XIÆ. The name of an order in the class *locales* of Cullen's nosology, which he divides into two sections, appetitus erronei and deficientes.

DYSPE'PSIA. (From δυς, bad, and ϖεπτω, to concoct.) *Apepsia.* Indigestion. Dr. Cullen arranges this genus of disease in the class *neuroses,* and order *adynamiæ.* It chiefly arises in persons between thirty and forty years of age, and is principally to be met with in those who devote much time to study, or who lead either a very sedentary or irregular life. A great singularity attendant on it is, that it may and often does continue a great length of time, without any aggravation or remission of the symptoms.

Great grief and uneasiness of mind, intense study, profuse evacuations, excess in venery, hard drinking, particularly of spirituous liquors, and of tea, tobacco, opium, and other narcotics, immoderate repletion, and over distension of the stomach, a deficiency in the secretion of the bile, or gastric juice, and the being much exposed to moist and cold air, when without exercise, are the causes which usually occasion dyspepsia.

A long train of nervous symptoms generally attend on this disease, such as a loss of appetite, nausea, heart-burn, flatulency, acid, fœtid, or nidorous eructations, a gnawing in the stomach when empty, a sense of constriction and uneasiness in the throat, with pain in the side, or sternum, so that the patient at times can only lay on his right side; great costiveness, habitual chilliness, paleness of the countenance, languor, unwillingness to move about, lowness of spirits, palpitations, and disturbed sleep.

The number of these symptoms varies in different cases, with some, being felt only in part; in others, being accompanied even with additional ones, equally unpleasant, such as severe transient pains in the head and breast, and various affections of the sight, as blindness, double vision, &c.

Dyspepsia never proves fatal, unless when, by a very long continuance, it produces great general debility and weakness; and so passes into some other disease, such as dropsy; but it is at all times very difficult to remove, but more particularly so in warm climates.

The morbid appearances to be observed on dissections of this disease, are principally confined to that part of the stomach which is called the pylorus; which is often found either in a contracted, scirrhous, or ulcerated state. In every instance, the stomach is perceived to be considerably distended with air.

The treatment of dyspepsia consists, 1. In obviating the several exciting causes. 2. In relieving urgent symptoms, some of which may tend to prolong the disease. 3. In restoring the tone of the stomach, or of the general system, and thus getting rid of the liability to relapse.

I. In fulfilling the first indication we are often much circumscribed by the circumstances or habits of the patient; and particularly when they have been accustomed to drink spirits, which they can hardly relinquish, or only in a very gradual manner. The diet must be regulated by the particular form of the disease: in those who are liable to acidity, it should be chiefly of an animal nature, with the least acescent vegetable substances, and for drink, toast and water, or soda water, adding a little brandy, if really necessary; where the opposite, or septic tendency appears, which happens especially in persons of a florid complexion, it should consist principally of vegetable matter, particularly the ripe subacid fruits, with the meat of young animals occasionally, and if plain water be not agreeable, table-beer, cyder, &c. may be allowed for drink; and in those of the phlegmatic temperament the most nutritious and digestible articles must be selected, mostly of an animal nature, assisted by the warmer condiments, and the more generous fermented liquors in moderation. It will be generally better to take food oftener, rather than to load the stomach too much at once; but more than four meals in the day can hardly be requisite; if at any other time a craving should occur, a crust of bread or a piece of biscuit may be eaten.

II. Among the symptoms requiring palliation, heart-burn is frequent, resulting from acrimony in the stomach, and to be relieved by antacid, or antiseptic remedies according to circumstances, or diluents and demulcents may answer the purpose. A sense of weight at the stomach with nausea may occasionally indicate a gentle emetic; but will be less likely to occur if the bowels are kept regular. Flatulence may be relieved by aromatics, æther, &c.; and these will be proper for spasmodic, or nervous pains; but if ineffectual, opium should be had recourse to. Vomiting is generally best checked by carbonic acid. When diarrhœa occurs, the aromatic confection is mostly proper, sometimes with a little opium. But the bowels are much more commonly confined, and mild cathartics should be frequently exhibited, as castor oil, rhubarb, aloes, &c.; sometimes the more active, where these do not answer; in those of a florid complexion a laxative diet, with the supertartrate of potash, or other saline cathartic occasionally, may agree better: and where the liver is torpid, mercurials should be resorted to.

III. The third object is to be attempted by tonics, particularly the aromatic bitters, the mineral acids, or the preparations of iron; by the cold bath prudently regulated; by gentle exercise steadily persevered in, particularly walking or riding on horseback; by a careful attention to the diet; by seeking a pure mild air, keeping regular hours, with relaxation and amusement of the mind, &c.

DYSPERMATI'SMUS. (From δυς, bad, and σπερμα, seed.) *Agenesia.* Slow, or impeded emission of semen, during coition, insufficient for the purpose of generation. A genus of disease in the class *locales,* and order *epischeses* of Cullen. The species are: 1. *Dyspermatismus urethralis,* when the obstruction is in the urethra. 2. *Dyspermatismus nodosus,* when a tumour is formed in either corpus cavernosum penis. 3. *Dyspermatismus præputialis,* when the impediment is from a straightness of the orifice of the præpuce. 4. *Dyspermatismus mucosus,* when the urethra is obstructed by a viscid mucus. 5. *Dyspermatismus hypertonicus,* when there is an excess of erection of the penis. 6. *Dyspermatismus epilepticus,* from epileptic fits coming on during coition. 7. *Dyspermatismus apractodes,* from a want of vigour in the genitals. 8. *Dyspermatismus refluus,* in which the semen is thrown back into the urinary bladder.

DYSPHA'GIA. (From δυς, with difficulty, and φαγω, to eat.) A difficulty of deglutition.

DYSPHO'NIA. (From δυς, bad, and φωνη, the voice.) A difficulty of speaking.

DYSPNŒ'A. (From δυς, difficult, and πνεω, to breathe.) *Dyspnoon.* Difficult respiration, without sense of stricture, and accompanied with cough through the whole course of the disease. A genus of disease in the class *neuroses,* and order *spasmi* of Cullen. He distinguishes eight species. 1. *Dyspnœa catarrhalis,* when with a cough there are copious discharges of viscid mucus, called also *asthma catarrhale, pneumodes, pneumonicum,* and *pituitosum.* 2. *Dyspnœa sicca,* when there is a cough without any considerable discharge. 3. *Dyspnœa aërea,* when the disease is much increased by slight changes of the weather. 4. *Dyspnœa terrea,* when earthy or calculous matters are spit up. 5. *Dyspnœa aquosa,* when there is a scarcity of urine and œdematous feet, without the other symptoms of a dropsy in the chest. 6. *Dyspnœa pinguedinosa,* from corpulency. 7. *Dyspnœa thoracica,* when parts surrounding the chest are injured, or deformed. 8. *Dyspnœa extrinseca,* from manifest external causes.

Dy'spnoon. See *Dyspnœa.*

Dysra'chitis. The name of a plaster in Galen.

Dysthy'mia. (From δυς, bad, and θυμος, mind.) Insanity.

Dysto'chia. (From δυς, with difficulty, and τικτω, to bring forth.) Difficult labour or child-birth.

DYSTŒCHI'ASIS. (From δυς, bad, and ϛοιχος, order.) An irregular disposition of the hairs in the eyelids.

DYSU'RIA. (From δυς, difficultly, and ουρον, urine.) *Stillicidium. Ardor urinæ. Culbicio.* A suppression or difficulty in discharging the urine. A total suppression is called ischuria; a partial suppression, dysuria: and this may be with or without heat. When there are frequent, painful, or uneasy urgings to discharge the urine, and it passes off only by drops, or in very small quantities, the disease is called strangury. When a sense of pain, or heat, attends the discharge it passes with difficulty, and is styled ardor urinæ, *heat* of the urine. The dysuria is acute, or chronic. Dr. Cullen places this disease in the class *locales,* and order *epischeses*, containing six species: 1. *Dysuria ardens*, with a sense of heat, without any manifest disorder of the bladder. 2. *Dysuria spasmodica*, from spasm. 3. *Dysuria compressionis*, from a compression of the neighbouring parts. 4. *Dysuria phlogistica*, from violent inflammation. 5. *Dysuria calculosa*, from stone in the bladder. 6. *Dysuria mucosa*, from an abundant secretion of mucus. The causes which give rise to these diseases are, an inflammation of the urethra, occasioned either by venereal sores, or by the use of acrid injections, tumour, ulcer of the prostate gland, inflammation of the kidneys, or bladder, considerable enlargements of the hemorrhoidal veins, a lodgment of indurated fæces in the rectum, spasm at the neck of the bladder, the absorption of cantharides, applied externally or taken internally, and excess in drinking either spirituous or vinous liquors; but particles of gravel, sticking at the neck of the bladder, or lodging in the urethra, and thereby producing irritation, prove the most frequent cause. Gouty matter falling on the neck of the bladder, will sometimes occasion these complaints.

In dysury, there is a frequent inclination to make water, with a smarting pain, heat, and difficulty in voiding it, together with a sense of fulness in the region of the bladder. The symptoms often vary, however, according to the cause which has given rise to it. If it proceeds from a calculus in the kidney or ureter, besides the affections mentioned, it will be accompanied with nausea, vomiting, and acute pains in the loins and region of the ureter and kidney of the side affected. When a stone in the bladder, or gravel in the urethra, is the cause, an acute pain will be felt at the end of the penis, particularly on voiding the last drops of urine, and the stream of water will either be divided into two, or be discharged in a twisted manner, not unlike a cork-screw. If a scirrhus of the prostate gland has occasioned the suppression or difficulty of urine, a hard indolent tumour, unattended with any acute pain, may readily be felt in the perinæum, or by introducing the finger into the rectum.

E.

EAR. *Auris.* The organ of hearing is situated at the side of the head, and is divided into external and internal ear. The *auricula*, commonly called the ear, constitutes the external part, and contains several eminences and depressions, as the *helix*, *antihelix*, *tragus*, *antitragus*, *concha auriculæ*, *scapha*, and *lobulus*. The external auditory passage, containing the wax, proceeds from the middle of it down to the membrane of the tympanum, which divides the external from the internal parts of this organ. Behind the membrana tympani is an irregular cavity, the cavity of the tympanum, in which are four little bones, the *malleus*, *incus*, *stapes*, and *os orbiculare*; and four openings, one of the Eustachian tube, another to the mastoid sinus, the fenestra ovalis, and the fenestra rotunda. The tympanum is terminated by the labyrinth. The labyrinth is the remaining part of the internal ear, consisting of the *cochlea*, *vestibulum*, and *semicircular canals*. The arteries of the ear are the external and internal auditory. The veins empty themselves into the external jugulars. The muscles of the ear are divided into three classes: the common, proper, and internal. The common muscles are, the *attollens aurem*, *anterior auris*, and *retrahentes auris*, which move the whole ear. The proper are, *helicis major*, *helicis minor*, *tragicus*, *antitragicus*, and *transversus auris*: these affect the parts only to which they are connected. The muscles of the internal ear are, *laxator tympani*, *tensor tympani*, and *stapedius*, which belong to the ossicula auditus. The nerves of the external ear are branches of the *nervus auditorius durus*, and those of the internal ear, are branches of the *nervus auditorius mollis*.

EARI'TES. Hæmatites, or blood-stone.

EARTH. *Terra.* Though there seems to be an almost infinite variety of earthy substances scattered on the surface of this globe, yet when we examine them with a chemical eye, we find, not without surprise, that all the earth and stones which we tread under our feet, and which compose the largest rocks, as well as the numerous different specimens which adorn the cabinets of the curious, are composed of a very few simple or elementary earths, in number no more than nine or ten: viz. Silex, lime, magnesia, barytes, strontian, alumine, glucine, zircon, yttria, and perhaps agustine.

These are all the simple earths hitherto known, which nature presents to us completely formed; though one or more of them enters into the composition of a great many bodies. They have a variety of properties which are common to all:—they are dry, incombustible bodies. They are insoluble in water and alkohol, or nearly so, and have little or no taste; at least when combined with carbonic acid. Their specific gravity does not exceed 4.9. When perfectly pure, they assume the form of a white powder, harsh to the touch. They are infusible. They are capable, except silex, of combining with acids, and forming neutral salts. They are likewise disposed to unite with the alkalies, with sulphur, and phosphorus; with metallic oxides, and with each other, either by fusion or solution in water.

Every one of these characters is not perhaps rigorously applicable to each of these bodies; but they all possess a sufficient number of them to render it useful to arrange them under one class. It has been recently shown by chemists, that some of the earths are really compounds of metallic substances with oxygen, and probably that will be found to hold true in them all.

Stones differ from earths principally in cohesion and hardness, and therefore are included under the same general name.

Earth, absorbent. See *Absorbents.*

Earth, aluminous. Earth which contains alumina. See *Alumine.*

Earth, animal calcareous. This term is applied to crabs'-claws, &c. which contain calcareous earth, and are obtained from the animal kingdom.

Earth, argillaceous. See *Alumine.*

Earth-bath. A remedy recommended by some writers on the continent, as a specific in consumption. In this country it produced to the patients very distressing sensations of cold; in some it seemed to be productive of bad effects; and it does not appear that, in any consumptive cases, good effects were ever derived from its use.

Earth, bolar. See *Bole.*

Earth, fullers'. *Cimolia purpurescens.* A compact bolar earth, commonly of a greyish colour. It is sometimes applied by the common people to inflamed breasts, legs, &c. with a view of cooling them.

Earth, heavy. See *Barytes.*

Earth, Japan. See *Acacia catechu.*

Earth, mineral calcareous. Those calcareous earths which are obtained from the mineral kingdom. The term is applied in opposition to those obtained from animals.

Earth-nut. See *Bunium.*

Earth, sealed. *Terra sigillata.* Little cakes of bolar earths, which are stamped with impressions. They were formerly in high estimation as absorbents, but now fallen into disuse.

Earth-worm. *Lumbricus terrestris. Vermis terrestris.* These insects are supposed to possess a diuretic and antispasmodic virtue, with which views they are occasionally employed in foreign countries.

Ear-wax. *Cerumen aurium.* A waxy secretion found in the meatus auditorius externus, into which it is separated by the glands around that canal.

Eaton's styptic. French brandy highly impregnated with calcined green vitriol. A remedy for checking hæmorrhages.

Eau-de-luce. See *Spiritus ammoniæ succinatus.*

Eau-de-rabel. This is composed of one part of sulphurous acid to three of rectified spirit of wine. It is much used in France, when diluted, in the cure of gonorrhœas, leucorrhœa, &c.

Ebel. The seeds of sage, or of juniper.

Ebe'num. Indian ebony. It is supposed to be ophthalmic.

Ebe'smech. A name in Langius for quicksilver.

Ebi'scus. The hibiscus, or marsh mallow.

Ebrieca'tum. (From *ebrio,* to be drunk.) By this term Paracelsus expresses loss of sense by drunkenness.

Ebrieca'tum cæle'ste. By this term Paracelsus means that kind of enthusiasm which is affected by many heathen priests.

Ebsemech. A name for quicksilver.

EBULLI'TION. (From *ebullio,* to bubble up.) *Ebullitio.* Boiling. This consists in the change which a fluid undergoes from a state of liquidity to that of an elastic fluid, in consequence of the application of heat, which dilates and converts it into vapour.

E'BULUS. (From *ebullio,* to make boil; so called because of its supposed use in purifying the humours of the body.) See *Sambucus ebulus.*

Ecbo'lica. (From εκϐαλλω, to cast out.) Medicines which were formerly said to cause abortion.

Ecbo'lios. (From εκϐαλλω, to cast out.) Miscarriage.

Ecbra'smata. (From εκϐραζω, to be very hot.) *Ecchymata.* Painful fiery pimples in the face, or surface of the body.

Ecbra'smus. (From εκϐραζω, to become hot.) Fermentation.

Ecbyrso'mata. (From εκ, and βυρσα, the skin.) Protuberances of the bones at the joints, which appear through the skin.

Eccatha'rtica. (From εκκαθαιρω, to purge outwards.) According to Gorræus, eccathartics are medicines which open the pores of the skin; but in general they are understood to be deobstruents. Sometimes expectorants are thus called, and also purgatives.

Ecchylo'ma. (From εκ, and χυλος, juice.) An extract.

Ecchy'mata. (From εκχυω, to pour out.) See *Ecbrasmata.*

ECCHYMO'MA. (Εκχυμωμα: from εκχυω, to pour out.) *Ecchymosis.* Sometimes called *crustula* and *sugillatio.* Extravasation. A black and blue swelling, either from a bruise or spontaneous extravasation of blood. A genus of disease in the class *locales*, and order *tumores* of Cullen.

Ecchymo'ma arterio'sum. The false aneurism.

Ecchymo'sis. See *Ecchymoma*.

E'cclisis. (From εκκλινω, to turn aside.) A luxation or dislocation.

E'ccope. (From εκκοπτω, to cut off.) The cutting off any part.

Ecco'peus. (From εκκοπτω, to cut off.) An antient instrument, the raspatory, used in trepanning.

Eccopro'tica. (From εκ, and κοπρος, dung.) Opening medicines, whose operation is very gentle; such as manna, senna, &c.

Eccrinocri'tica. (From εκκρινω, to secrete, and κρινω, to judge.) Judgments formed from the secretions.

Eccrinolo'gia. *Eccrinologica.* (From εκκρινω, to secrete, and λογος, a discourse.) The doctrine of secretions.

E'ccrisis. (From εκκρινω, to secrete.) A secretion of any kind.

Eccymo'sis. See *Ecchymoma*.

E'cdora. (From εκδερω, to excoriate.) An excoriation: and particularly used for an excoriation of the urethra.

Ecdo'ria. (From εκδερω, to excoriate.) Medicines which excoriate and burn through the skin.

Echeco'llon. (From εχω, to have, and κολλα, glue.) *Echecollum.* Any topical glutinous remedy.

Echetro'sis. So Hippocrates calls the white briony.

Echini'des. In Hippocrates it is mentioned as what he used for purging the womb with.

Echinophtha'lmia. (From εχινος, a hedge-hog, and οφθαλμια, an inflammation of the eye.) An inflammation of the hairy part of the eyelids, where the hairs bristle out like the quills of an echinus, or hedgehog.

Echinopo'dium. (From εχινος, a hedgehog, and πους, a foot; so named because its flowers resemble the foot of an urchin.) A species of broom, or genista.

Echi'nops. (From εχινος, as beset with prickles.) *Crocodilion. Acanthalruca, Scabiosa carduifolia. Sphærocephala elatior. Echinopus.* Globe thistle. *Echinops sphærocephalus* of Linnæus. It is raised in our gardens. The root and seeds are moderately diuretic, but not used.

Echi'nopus. See *Echinops*.

E'CHIUM. (From εχις, a viper; so called because it was said to heal the stings of vipers.) The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Monogynia.* Viper's bugloss.

E'chium Ægypti'acum. Wall bugloss; vulnerary, sudorific.

E'chos. (Ηχος, sound.) In Hippocrates it signifies the same as the tinnitus aurium, or noise in the ears.

E'chysis. (From εχυω, to pour out.) A fainting, or swooning.

Ecla'mpsia. (From εκλαμπω, to shine.) See *Eclampsis*.

ECLA'MPSIS. (From εκλαμπω, to shine.) *Eclampsia.* It signifies a splendour, brightness, effulgence, flashing of light, scintillation. It is a flashing light or those sparklings which strike the eyes of epileptic patients. Cœlius Aurelianus calls them *circuli ignei,* scintillations, or fiery circles. Though only a symptom of the epilepsy, Hippocrates puts it for epilepsy itself.

Ecle'ctica. (From εκλεγω, to select.) Archigenes and some others selected from all other sects what appeared to them to be the best and most rational; hence they were called *Eclectics,* and their medicine *Eclectic medicine.*

Ecle'ctos. (From εκλειχω, to lick up.) A linctus, or soft medicine to be licked up.

Ecle'gma. (From εκλειχω, to lick.) Is a form of medicine made by the incorporation of oils with syrups, and which is to be taken upon a liquorice stick; the same as *Linctus.*

E'clysis. (From εκλυω, to dissolve.) An universal faintness.

Ecma'gma. (From εκμασσω, to form together.) A mass of substances kneaded together.

Ecpepie'menos. (From εκπιεζω, to press out.) An epithet for ulcers with protuberating lips.

Ecphra'ctic. (From εκφρασσω, to remove obstructions.) Are such medicines as incide and render more thin tough humours, so as to promote their discharge.

Ecphra'ctica. (From εκφρασσω, to remove obstructions.) Deobstruent medicines.

Ecphra'xis. (From εκφρασσω, to remove obstruction.) A diaphoresis; an opening of the pores.

E'cphyas. (From εκ, and φυω, to produce.) An appendix, or excrescence. Some call the appendicula vermiformis thus.

E'cphyse. (From εκφυσαω, to blow out.) Flatus from the bladder through the urethra, and from the womb through the vagina.

Ecphyse'sis. (From εκφυσαω, to breathe through.) A quick expulsion of the air from the lungs.

E'cphysis. (From εκφυω, to produce.) An apophysis, or appendix. A process.

Ecpie'sma. (From εκπιεζω, to press out.) A fracture of the skull, in which the bones press inwardly.

Ecpie'smos. (From εκπιεζω, to press out.) A disorder of the eye, in which the globe is almost pressed out of the socket by an afflux of humours.

Ecplero'ma. (From εκπληροω, to fill.) In Hippocrates they are hard balls of leather, or other substances, adapted to fill the arm-pits, while by the help of the heels, placed against the balls, and repressing the same, the luxated os humeri is reduced into its place.

Ecple′xis. (From εκπλησσω, to terrify or astonish.) A stupor, or astonishment, from sudden external accidents.

E′cpnoe. (From εκϖνεω, to breathe.) Expiration; that part of respiration in which the air is expelled from the lungs.

Ecpto′ma. (From εκπιπτω, to fall out.)

1. A luxation of a bone.
2. The exclusion of the secundines.
3. Speaking of corrupt parts, it signifies a falling off.
4. An hernia in the scrotum.
5. A falling down of the womb.

Ecpy′ctica. (From εκπυκαζω, to condense.) Incrassants. Medicines that render the fluids more solid.

Ecpye′ma. (From εκ, and πυον, pus.) A copious collection of pus or matter, from the suppuration of a tumour.

Ecre′gma. (From εκρηγνυμι, to break.) A rupture.

Ecre′xis. (From εκρηγνυμι, to break.) A rupture. Hippocrates expresses by it a rupture or laceration of the womb.

Ecrhy′thmos. (From εκ, and ρυθμος, harmony.) A term applied to the pulse, and signifies that it is disorderly or irregular.

E′croe. (From εκρεω, to flow out.) An efflux, or the course by which any humour which requires purging is evacuated.

Ecruelles. The French name for scrophula.

E′crysis. (From εκρεω, to flow out.) In Hippocrates it is an efflux of the semen before it receives the conformation of a fœtus, and therefore is called an efflux, to distinguish it from abortion.

Ecsarco′ma. (From εκ, and σαρξ, flesh.) A fleshy excrescence.

E′CSTASIS. (Εκϛασις: from εξιϛαμαι, to be out of one's senses.) An ecstacy, or trance. In Hippocrates it signifies a delirium. Dr. Cullen ranks it as a kind of apoplexy.

Ecstro′phius. (From εκϛρεφω, to invert.) An epithet for any medicine, that makes the blind piles appear outwardly.

Ecthely′nsis. (From εκθηλυνω, to render effeminate.) Softness. It is applied to the skin and flesh, when lax and soft, and to bandages, when not sufficiently tight.

Ecthli′mma. (From εκθλιϐω, to press out against.) An ulceration caused by pressure of the skin.

Ecthli′psis. (From εκθλιϐω, to press out against.) Elision, or expression. It is spoken of swelled eyes, when they dart forth sparks of light.

E′cthyma. (From εκθυω, to break out.) A pustule, or cutaneous eruption.

Ecthy′mata. (From εκθυω, to break out.) Pimples, pustules, or cutaneous eruptions.

Ectillo′tica. (From εκτιλλω, to pull out.) Medicines which eradicate tubercles or corns, or destroy superfluous hair.

ECTO′PIA. (From εκτοπος, out of place.) Displaced.

ECTO′PIÆ. Parts displaced. An order in the class *locales* of Cullen's nosology.

Ectrapeloga′stros. (From εκτρεπομαι, to degenerate, and γαϛηρ, a belly.) One who has a monstrous belly, or whose appetite is voraciously large.

Ectri′mma. (From εκτριϐω, to rub off.) An attrition, or galling. In Hippocrates it is an exulceration of the skin about the os sacrum.

E′ctrope. (From εκτρεπω, to divert, pervert, or invert.) It is any duct by which the humours are diverted and drawn off. In P. Ægineta it is the same as *Ectropium.*

ECTRO′PIUM. (From εκτρεπω, to evert.) An eversion of the eyelids so that their internal surface is outermost.

There are two species of this disease; one produced by an unnatural swelling of the lining of the eyelids, which not only pushes their edges from the eyeball, but also presses them so forcibly, that they become everted; the other arising from a contraction of the skin covering the eyelid, or of that in the vicinity, by which means the edge of the eyelid is first removed for some distance from the eye, and afterwards turned completely outward, together with the whole of the affected eyelid.

The morbid swelling of the lining of the eyelids, which causes the first species of ectropium, arises mostly from a congenital laxity of this membrane, afterwards increased by obstinate chronic ophthalmies, particularly of a scrophulous nature, in relaxed, unhealthy subjects; or else the disease originates from the small-pox affecting the eyes.

While the disease is confined to the lower eyelid, as it most commonly is, the lining of this part may be observed rising in the form of a semilunar fold, of a pale red colour, like the fungous granulations of wounds, and intervening between the eye and eyelid, which latter it in some measure everts. When the swelling is afterwards occasioned by the lining of both the eyelids, the disease assumes an annular shape, in the centre of which the eyeball seems sunk, while the circumference of the ring presses and everts the edges of the two eyelids, so as to cause both great uneasiness and deformity. In each of the above cases, on pressing the skin of the eyelids with the point of the finger, it becomes manifest that they are very capable of being elongated, and would readily yield, so as entirely to cover the eyeball, were they not prevented by the intervening swelling of their membranous lining.

Besides the very considerable deformity

which the disease produces, it occasions a continual discharge of tears over the cheek, and, what is worse, a dryness of the eyeball, frequent exasperated attacks of chronic ophthalmy, incapacity to bear the light, and lastly, opacity and ulceration of the cornea.

The second species of ectropium, or that arising from a contraction of the integuments of the eyelids, or neighbouring parts, is not unfrequently a consequence of puckered scars, produced by the confluent smallpox, deep burns, or the excision of cancerous or encysted tumours, without saving a sufficient quantity of skin; or lastly, the disorder is the effect of malignant carbuncles, or any kind of wound attended with much loss of substance. Each of these causes is quite enough to bring on such a contraction of the skin of the eyelids as to draw the parts towards the arches of the orbits, so as to remove them from the eyeball, and turn their edges outward. No sooner has this circumstance happened, than it is often followed by another one equally unpleasant, namely, a swelling of the internal membrane of the affected eyelids, which afterwards has a great share in completing the eversion. The lining of the eyelids, though trivially everted, being continually exposed to the air, and irritation of extraneous substances, soon swells, and rises up like fungus. One side of this fungus-like tumour covers a part of the eye-ball; the other pushes the eyelid so considerably outwards, that its edge is not unfrequently in contact with the margin of the orbit. The complaints induced by this second species of ectropium are the same as those brought on by the first; it being noticed, however, that in both cases, whenever the disease is very inveterate, the fungous swelling of the inside of the eyelids becomes hard, coriaceous, and as it were callous.

Although, in both species of ectropium, the lining of the eyelids seems equally swollen, yet the surgeon can easily distinguish to which of the two species the disease belongs. For, in the first, the skin of the eyelids, and adjoining parts, is not deformed with scars; and by pressing the everted eyelid with the point of the finger, the part would with ease cover the eye, were it not for the intervening fungous swelling. But in the second species of ectropium, besides the obvious cicatrix and contraction of the skin of the eyelids, or adjacent parts, when an effort is made to cover the eye with the everted eyelid, by pressing upon the latter part with the point of the finger, it does not give way so as completely to cover the globe, as it ought to do, only yielding for a certain extent: or it does not move in the least from its unnatural position, by reason of the integuments of the eyelids having been so extensively destroyed, that their margin has become adherent to the arch of the orbit.

Ectro′sis. (Εκτρωσις: from εκτιτρωσκω, to miscarry.) A miscarriage.

Ectro′tica. (From εκτιτρωσκω, to miscarry.) *Ectyrotica.* Medicines which cause abortion.

Ectylo′tica. See *Ectillotica.*

Ectyro′tica. See *Ectrotica.*

Ecze′ma. (From εκζεω, to boil out.) *Eczesma.* A hot, painful eruption, or pustule. Mr. Pearson calls the erythema mercuriale, eczema mercuriale.

Ede′lphus. Prognosis from the nature of elements.

E′dèra trifo′lia. The poison-tree of America.

E′des. A name for amber.

Ede′ssenum. *Pelarium.* An eye-water of tragacanth, arabic, acacia, opium, &c.

E′detz. Amber.

E′dic. *Edich. Edir.* An old name for iron.

E′dra. A fracture; also the lower part of the rectum.

Edulcora′ntia. (From *edulco,* to make sweet.) Edulcorants. Sweeteners. Medicines which absorb the vicious humours of the body, sweeten the fluids, and deprive them of their acrimony.

EFFERVESCENCE. (From *effervesco,* to grow hot.) *Effervescentia.* That agitation which is produced by mixing substances together, which cause the evolution of a gas. A small degree of ebullition.

E′ffides. An old name for ceruss.

E′ffila. Freckles.

EFFLORESCENCE. (From *effloresco,* to blow as a flower.) *Efflorescentia.*

1. A preternatural redness of the skin.
2. In chemistry, it means that phenomenon which takes place upon crystals, producing a white powder when exposed to air.

EFFLU′VIUM. (From *effluo,* to spread abroad.) See *Contagion.*

Effractu′ra. (From *effringo,* to break down.) *Ecpiesma.* A species of fracture, in which the bone is much depressed by the blow.

EFFUSION. (From *effundo,* to pour out.) *Effusio.* In surgery, it means the escape of any fluid out of the vessel, or viscus, naturally containing it, and its lodgment in another cavity, in the cellular substance, or in the substance of parts. Effusion also sometimes signifies the natural secretion of fluids from the vessels; thus surgeons frequently speak of the coagulable lymph being effused on different surfaces.

Ege′ries. (From *egero,* to carry out.) *Egestio.* An excretion, or evacuation.

EGG. *Ovum.* The eggs of poultry are chiefly used as food: the different parts are likewise employed in pharmacy and in medicine. The calcined shell is esteemed as an absorbent. The oil of the egg is softening, and is used externally to burns and chaps. The yolk of the egg renders oil miscible with water, and is triturated with the same view with resinous and other substances. Raw eggs have been much recommended as a popular remedy for jaundice.

Egrego′rsis. (From εγρηγορεω, to watch.) A watchfulness. A morbid want of sleep.

Ejacula′ntia. (From *ejaculo*, to cast out.) *Ejaculatoria.* The vessels which convey the seminal matter secreted in the testicles to the penis. These are the epididymis, and the vasa deferentia; the vesiculæ seminales are the receptacles of the semen.

Eje′ctio. (From *ejicio*, to cast out.) *Excretio.* The discharging of humours or excrements.

Ei′lamis. (From ειλεω, to involve.) A membrane involving the brain.

Eile′ma. (From ειλεω, to form convolutions.) In Hippocrates, it signifies painful convolutions of the intestines from flatulence. Sometimes it signifies a covering. Vogel says, it is a fixed pain in the bowels, as if a nail was driven in.

Ei′leon. (From ειλεω, to wind.) Gorræus says it is a name of the intestinum ileum.

Ei′leos. (From ειλεω, to form convolutions.) The iliac passion.

Ei′sbole. (From εις, into, and βαλλω, to cast.) It signifies strictly an injection, but is used to express the access of a distemper, or of a particular paroxysm.

Ei′spnoe. (From εις, into, and πνεω, to breathe.) Inspiration of air.

Ela ca′lli. An Indian cathartic shrub, the *Euphorbia neriifolia* of Linnæus.

Elæa′gnon. (From ελαιον, oil, and αγνος, chaste.) The agnus castus was formerly so called.

Elæo′meli. (From ελαιον, oil, and μελι, honey.) A sweet purging oil, like honey.

Elæosa′ccharum. (From ελαιον, oil, and σακχαρον, sugar.) A mixture of essential oil with sugar.

Elæoseli′num. Water parsley. See *Eleoselinum.*

Elais guinee′nsis. A species of palm which grows spontaneously on the coast of Guinea, but is much cultivated in the West Indies. From this tree, according to some, is obtained the palm-oil, which is considered as an emollient and strengthener of all kinds of weakness of the limbs. It also is recommended against bruises, strains, cramps, pains, swellings, &c.

Elambica′tio. A method of analysing mineral waters.

Ela′nula. An old name for alum.

Elaphobo′scum. (From ελαφος, a stag, and βοσκω, to eat; so called, because deer eat them greedily.) The wild parsnep. See *Pastinaca.*

Elaphosco′rodon. (From ελαφος, the stag, and σκοροδον, garlic.) Stag's or viper's garlic.

E′laquir. Red Vitriol.

E′las ma′ris. Burnt lead.

Ela′sma. (From ελαυνω, to drive.) A lamina or plate of any kind. A term used to express a clyster-pipe.

Elastic fluid. See *Gaz.*

Elastic gum. See *Siphonia elastica.*

ELASTICITY. A force in bodies, by which they endeavour to restore themselves to the posture from whence they were displaced by any external force. To solve this property, many have recourse to the universal law of nature, attraction, by which the parts of solid and firm bodies are caused to cohere together: whereby, when hard bodies are struck or bent, so that the component parts are a little moved from one another, but not quite disjoined or broken off, nor separated so far as to be out of the power of the attracting force, by which they cohere together; they certainly must, on the cessation of the external violence, spring back with a very great velocity to their former state. But in this circumstance, the atmospherical pressure will account for it as well; because such a violence, if it be not great enough to separate the constituent particles of a body far enough to let in any foreign matter, must occasion many vacuola between the separated surfaces, so that upon the removal of the external force, they will close again by the pressure of the aërial fluid upon the external parts, i. e. the body will come again into its natural posture. The included air, likewise, in most bodies, gives that power of resilition upon their percussion.

If two bodies perfectly *elastic* strike one against another, there will be or remain in each the same relative velocity as before, i. e. they will recede with the same velocity as they met together. For the compressive force, or the magnitude of the stroke in any given bodies, arises from the relative velocity of those bodies, and is proportional to it: and bodies perfectly *elastic* will restore themselves completely to the figure they had before the shock; or, in other words, the restitutive force is equal to the compressive, and therefore must be equal to the force with which they came together, and consequently they must by elasticity recede again from each other with the same velocity. Hence, taking equal times before and after the shock, the distances between the bodies will be equal; and therefore the distances of them from the common centre of gravity will, in the same times, be equal. And hence the laws of percussion of bodies perfectly elastic are easily deduced.

ELATE′RIUM. (From ελαυνω, to stimulate or agitate: so named from its great purgative qualities.) See *Momordica Elaterium.*

Elathe′ria. A name for the cascarilla bark.

Elati′ne. (From ελαττων, smaller, being the smaller species.) See *Antirrhinum Elatine.*

Elati'tes. Bloodstone.

Elco'sis. (From ελκος, an ulcer.) A disease attended with fœtid, carious, and chronic ulcers. The term is seldom used.

Elder. See *Sambucus.*

Elder dwarf. See *Sambucus Ebulus.*

Elecampane. See *Inula helenium.*

ELECTRICITY. (*Electricitas,* from *electrum,* ηλεκτρον, from ηλεκτωρ, the sun, because of its bright shining colour; or from ελκω, to draw, because of its magnetic power.) A property which certain bodies possess when rubbed, heated, or otherwise excited, whereby they attract remote bodies, and frequently emit sparks or streams of light. The antients first observed this property in amber, which they called *electrum,* and hence arose the word electricity. The efficacy of electricity in the cure of several diseases has been supported by many very respectable authorities, especially in paralytic diseases. It considerably augments the circulation of the blood, and excites the action of the absorbents.

Electro'des. (From ηλεκτρον, amber.) An epithet for stools which shine like amber.

Ele'ctrum minera'le. The tincture of metals. It is made of tin and copper, to which some add gold, and double its quantity of martial regulus of antimony melted together; from these there results a metallic mass, to which some chemists have given the name of *electrum minerale.* This mass is powdered and detonated with nitre and charcoal to a kind of scoria; it is powdered again whilst hot, and then digested in spirit of wine, whence a tincture is obtained of a fine red colour.

ELECTUA'RIUM. An electuary. The London Pharmacopœia refers those articles which were formerly called electuaries to confections.

Electua'rium antimo'nii. ℞. Electuarii sennæ, ℥j; guaiaci gummi, hydrargyri cum sulphure, antimonii ppti. sing. ℥ss; syrupi simplicis q. s. misce. Of this electuary, from a drachm to about two drachms is given twice a day, in those cutaneous diseases which go under the general name of scorbutic. It is usually accompanied with the decoctions of elm bark or sarsaparilla.

Electua'rium ca'ssiæ. See *Confectio cassiæ.*

Electua'rium ca'techu. *Confectio Japonica.* Electuary of catechu, commonly called Japonic confection. Take of mimosa catechu, four ounces; kino, three ounces; cinnamon, nutmeg, each one ounce; opium diffused in a sufficient quantity of Spanish white wine one drachm and a half; syrup of red roses boiled to the consistence of honey, two pounds and a quarter. Reduce the solids to powder, and, having mixed them with the opium and syrup, make them into an electuary. A very useful astringent, and perhaps the most efficacious way of giving the catechu to advantage. Ten scruples of this electuary contain one grain of opium.

Electua'rium cincho'næ cum na'tro. ℞ natri ppti ʒjj; pulveris cinchonæ unc: mucilaginis gummi arabici q. s. misce. In this composition mucilage is preferred to syrup on account of its covering the taste of the bark much more advantageously. It should, for this purpose, however, be made thin, otherwise it will increase the bulk of the electuary too much.

This remedy will be found an excellent substitute for the burnt sponge, whose powers as a remedy in scrophula, are known solely to depend on the proportion of natron contained in it. The dose is two drachms, twice or thrice a day.

Electua'rium opia'tum. See *Confectio opii.*

Eleli'sphacos. (From ελελιζω, to distort, and σφακος, sage: so named from the spiral coiling of its leaves and branches.) A species of sage.

Ele'mbrat. An obsolete term for alkaline salts.

ELEMENTS. Radicals. First principles. Substances which can no further be divided or decomposed by chemical analysis. However, though many substances cannot be decomposed by the chemist into constituent parts, this does not demonstrate them to be simple. Though they are as *yet not decomposed,* it does not follow that they are *undecomposable;* as, perhaps, neither our senses nor our instruments will ever reach those substances which by their nature admit of no sort of decomposition. But until sufficient proofs are given of their compound nature, sound philosophy requires us to consider them as simple bodies. It is not necessary, that the parts should have been actually separated from one another. Some substances are presumed to be compound from analogy; thus oxygen gas is considered as consisting of caloric and oxygen, though this last has never been exhibited in a separate state. The antients reckoned only four elements, fire, air, water, and earth: all of which are at present acknowledged to be compound. But on the other hand we have formed a much more numerous list: light, caloric, oxygen, azote, hydrogen, carbon, boron, sulphur, phosphorus, the metals, and the metallic bases of the earths, and fixed alkalies. Whether to these should be added the magnetic and electric fluids, with chlorine, fluorine and iodine, is not yet determined.

E'LEMI. (It is said this is the Ethiopian name.) Gum elemi. The parent plant of this resin is supposed to be the *Amyris elemifera,* which see.

E'lemi ungue'ntum. See *Unguentum elemi compositum.*

Elemni'fera curassa'vica a'rbor. The gum elemi-tree.

Ele'ngi. A tree of Malabar. Cardiac.

Eleochry'sum. (From ηλιος, the sun, and χρυσος, gold; so called from their shining yellow appearance.) Goldilocks. See *Gnaphalium Stœchas.*

Eleoseli'num. (From ελος, a lake, and σελινον, parsley.) See *Apium.*

Elepha'ntia. (From ελεφας, an elephant; so called from the great enlargement of the body in this disorder.) A species of anasarca.

Elepha'ntia a'rabum. In Dr. Cullen's nosology it is synonymous with elephantiasis. The term is, however, occasionally confined to this disease when it affects the feet.

ELEPHANTI'ASIS. (From ελεφας, an elephant; so named from the legs of people affected with this disorder growing scaly, rough, and wonderfully large, at an advanced period, like the legs of an elephant.) *Elephas. Elephantia. Lazari morbus vel malum. Phœniceus morbus.* A disease that attacks the whole body, but mostly affects the feet, which appear somewhat like those of the elephant. It is known by the skin being thick, rough, wrinkly, unctuous, and void of hair, and mostly without the sense of feeling. It is said to be contagious. Cullen makes it a genus of disease in the class *cachexiæ,* and order *impetigines.*

Elephantiasis has generally been supposed to arise in consequence of some slight attack of fever, on the cessation of which the morbid matter falls on the leg, and occasions a distension and tumefaction of the limb, which is afterwards overspread with uneven lumps, and deep fissures. By some authors it has been considered as a species of leprosy; but it often subsists for many years without being accompanied with any of the symptoms which characterise that disease.

It sometimes comes on gradually, without much previous indisposition; but more generally, the person is seized with a coldness and shivering, pains in the head, back, and loins, and some degree of nausea. A slight fever then ensues, and a severe pain is felt in one of the inguinal glands, which, after a short time, becomes hard, swelled, and inflamed. No suppuration, however, ensues; but a red streak may be observed running down the thigh from the swelled gland to the leg. As the inflammation increases in all the parts, the fever gradually abates, and perhaps, after two or three days continuance, goes off. It, however, returns again at uncertain periods, leaving the leg greatly swelled with varicose turgid veins, the skin rough and rugged, and a thickened membrana cellulosa. Scales appear also on the surface, which do not fall off, but are enlarged by the increasing thickness of the membranes; uneven lumps, with deep fissures, are formed, and the leg and foot become at last of an enormous size.

A person may labour under this disease many years, without finding much alteration in the general health, except during the continuance of the attacks; and perhaps the chief inconvenience he will experience is the enormous bulky leg which he drags about with him. The incumbrance has, indeed, induced many who have laboured under this disease to submit to an amputation; but the operation seldom proves a radical cure, as the other leg frequently becomes affected.

Hilary observes, that he never saw both legs swelled at the same time. Instances where they have alike acquired a frightful and prodigious size, have, however, frequently fallen under the observation of other physicians.

Elephanti'num emplastrum. A plaster described by Oribasius. Celsus describes one of the same name, but very different in qualities.

E'lephas. (Ελεφας, the elephant.) The disease called elephantiasis; also aqua fortis.

Ele'rsna. An obsolete term for black lead.

Ele'smatis. An old term for burnt lead.

Ele'ttari pri'mum. The true amomum.

ELETTA'RIA. (From *elettari.*) This is a new genus of plants formed by Dr. Maton, to which the lesser cardamom is referred. Class, *Monandria.* Order, *Monogynia.*

Eletta'ria cardamo'mum. *Cardamomum minus.* Lesser or officinal cardamom. *Amomum repens,* or *le cardamome de la côte de Malabar,* of Sonnerat. *Elettaria cardamomum,* of Maton, in Act. Soc. Lin. The seeds of this plant are imported in their capsules or husks, by which they are preserved, for they soon lose a part of their flavour when freed from this covering. On being chewed, they impart a glowing aromatic warmth, and grateful pungency; they are supposed gently to stimulate the stomach, and prove cordial, carminative, and antispasmodic, but without that irritation and heat which many of the other spicy aromatics are apt to produce. Simple and compound spirituous tinctures are prepared from them, and they are ordered as a spicy ingredient in many of the officinal compositions.

Eleuthe'ria bark. See *Croton cascarilla.*

Eleuthe'riæ co'rtex. See *Croton cascarilla.*

Eleva'tio. (From *elevo,* to lift up.) Elevation. Sublimation.

ELEVA'TOR. (From *elevo,* to lift up.) A muscle is so called whose office is to lift up the part to which it is attached. Also a chirurgical instrument, *elevatorium,* with which surgeons raise any depressed portion of bone, but chiefly those of the cranium.

Eleva'tor la'bii inferio'ris pro'prius. See *Levator labii inferioris.*

Eleva′tor la′bii superio′ris pro′prius. See *Levator labii superioris alæque nasi.*

Eleva′tor labio′rum. See *Levator anguli oris.*

Eleva′tor na′si ala′rum. Muscles of the alæ of the nose.

Eleva′tor o′culi. See *Rectus superior oculi.*

Eleva′tor pa′lpebræ superi′oris. See *Levator palpebræ superioris.*

Eleva′tor sca′pulæ. See *Levator scapulæ.*

Elevato′rium. (From *elevo*, to lift up.) An instrument to raise a depression in the skull.

Eli′banum. See *Juniperus lycia.*

Elichry′sum. (From *ηλιος*, the sun, and *χρυσος*, gold; so called from their shining yellow appearance.) See *Gnaphalium Stœchas.*

Eli′drion. Mastich; a mixture of brass.

Eli′gma. An old name for a linctus.

Elioseli′num. See *Eleoselinum.*

Elithroi′des. The vaginal coat of the testicle.

Elixa′tio. (From *elixo*, to boil.) The act of seething, or boiling.

ELI′XIR. (From *elekser*, an Arabic word signifying quintessence.) A term formerly applied to many preparations similar to compound tinctures. It is now very little employed.

Elixir of health. *Elixir salutis.* A term formerly applied to what is now called compound tincture of senna. See *Tinctura sennæ.*

Eli′xir parego′ricum. Paregoric elixir. See *Tinctura camphoræ composita.*

Eli′xir proprieta′tis. A preparation of aloes.

Eli′xir sa′crum. A tincture of rhubarb and aloes.

Eli′xir salu′tis. See *Tinct. Sennæ.*

Eli′xir stoma′chicum. Stomachic elixir. See *Tinctura gentianæ composita.*

Elixiva′tio. (From *elixo*, to boil, or from *lixivium*, lye.) The extraction of a fixed salt from vegetables, by an affusion of water.

Elle′borum. See *Helleborus* and *Veratrum.*

Elm. See *Ulmus.*

Elmi′nthes. (From ειλεω, to involve, from its contortions.) Worms.

Elm-leaved sumach. See *Rhus coriaria.*

Elo′des. (From ελος, a swamp.) A term given to a sweating fever, from its great moisture.

Elonga′tio. (From *elongo*, to lengthen out.) An imperfect luxation, where the ligament is only lengthened, and the bone not put out of its socket.

ELOY, Nicholas Francis Joseph, was born at Mons in 1714, and died in 1788, having practised as a physician with great ability and humanity. He had the honour of attending Prince Charles of Lorraine. He was a man of extensive learning, and, notwithstanding his professional avocations, was author of several publications. The principal of these, an Historical Medical Dictionary, was originally in two octavo volumes; but in 1778 it appeared greatly improved and enlarged in four volumes quarto. An Introduction to Midwifery; a Memoir on Dysentery; Reflections on the Use of Tea; and a Medico-Political Tract on Coffee; were likewise written by this author. The latter work procured him the reward of a superb snuff-box from the estates of Hainault, inscribed "Ex dono Patriæ."

ELUTRIATION. (From *elutrio*, to cleanse.) Washing over. It is the pouring a liquor out of one vessel into another, in order to separate the subsiding matter from the clear and fluid part.

Elu′vies. (From *eluo*, to wash out.) The effluvium from a swampy place. Also the humour discharged in fluor albus.

Eluxa′tio. (From *eluxo*, to put out of joint.) A luxation, or dislocation.

Elymagro′stis. (From *ελειμος*, the herb panic, and *αγρωϛις*, wild.) Wild panic.

Ely′mus. (Ελειμος.) The herb panic.

ELYOT, Sir Thomas, was born of a good family in Suffolk, about the beginning of the sixteenth century. After studying at Oxford, and improving himself by travelling, he was introduced at court; and Henry VIII. conferred upon him the honour of knighthood, and employed him in several embassies. He distinguished himself in various branches of learning, as well as by patronising learned men; and was generally beloved by his cotemporaries for his virtues and accomplishments. He died in 1546, and was buried in Cambridgeshire, of which he had been sheriff. Among other studies, he was partial to medicine, and made himself master of the ancient authors on that subject, though he never exercised the profession. He published a work about the year 1541, called "The Castell of Health," which was much admired, even by some of the faculty: in this he is a strong advocate for temperance, especially in sexual pleasures. He also notices, that catarrhs were much more common, than they had been forty years before; which he ascribes chiefly to free living, and keeping the head too much covered. He also wrote and translated several other works, but not on medical subjects.

ELYTROCE′LE. (From *ελυτρον*, the vagina, and *κηλη*, a tumour.) A hernia in the vagina.

Elytroi′des. (*Elytroides*; from *ελυτρον*, a sheath, and *ειδος*, form.) Like a sheath. The tunica vaginalis is so called by some writers, because it includes the testis like a sheath.

Ely′tron. (From ελυω, to involve.) The vagina. A sheath. The membranes which involve the spinal marrow are called elytra, ελυτρα.

Emargina′tio. (From *emargino*, to cleanse the edges.) The cleansing of the edges of wounds from scurf and filth.

Emascula′tus. (From *emasculo*, to render impotent.) Having the testicles in the belly, and not fallen into the scrotum.

Emba′mma. (From εμβαπτω, to immerge in.) A medicated pickle to dip the food in.

E′mbole. (From εμβαλλω, to put in.) The reduction or setting of a dislocated bone.

E′mbolum. (From εμβαλλω, to cast out; so named because it ejects the semen.) The penis.

Embre′gma. (From εμβρεχω, to make wet.) A fluid application to any part of the body.

EMBROCA′TIO. (From εμβρεχω, to moisten or soak in.) *Embroche.* An embrocation. A fluid application to rub any part of the body with. Many use the term, however, as synonymous with liniment. The following embrocations are noticed in the Pharmacopœia Chirurgica.

Embroca′tio alu′minis. ℞. Aluminis ʒjj. Aceti, spiritus vinosi tenuioris, sing. ℔ss. For chilblains and diseased joints.

Embroca′tio ammo′niæ. ℞ embrocationis ammoniæ acetatis ℥jj. Aquæ ammoniæ puræ ʒjj. For sprains and bruises.

Embroca′tio ammo′niæ aceta′tis ca′mphora′ta. ℞ solutionis saponis cum camphora, aquæ ammoniæ acetatæ sing. ℥j. Aquæ ammoniæ puræ ℥ss. For sprains and bruises. It is also frequently applied to disperse chilblains which have not suppurated. It is said to be the same as Steer's opodeldoc.

Embroca′tio ammo′niæ aceta′tis. ℞ aquæ ammoniæ acetatæ. Solutionis saponis sing. ℥j M. For bruises with inflammation.

Embroca′tio cantha′ridis cum ca′mphora. ℞ tinct. cantharidis. Spiritus camphoræ sing. ℥j M. This may be used in any case in which the object is to stimulate the skin. The absorption of cantharides, however, may bring on a strangury.

E′mbroche. See *Embrocatio.*

E′MBRYO. (From εμβρυω, to bud forth.) The *fœtus in utero* is so called before the fifth month of pregnancy, because its growth resembles that of the budding of a plant.

Embryothla′stes. (From εμβρυον, the fœtus, and θλαω, to break.) *Embryorectes.* A crotchet, or instrument for breaking the bones of a dead fœtus to promote its delivery.

EMBRYO′TOMY. (From εμβρυον, a fœtus, and τεμνω, to cut.) *Embryotomia.* The separating of any part of the fœtus whilst *in utero*, to extract it.

Embryu′lcus. (From εμβρυον, a fœtus, and ελκω, to draw.) A blunt hook, or forceps, for drawing the child from the womb.

E′merus. Scorpion senna. A laxative.

Eme′sia. (From εμεω, to vomit) *Emesma. Emesis.* The act of vomiting. Medicines which cause vomiting.

EME′TICS. (*Emetica*, sc. *medicamenta*; from εμεω, to vomit.) Substances capable of exciting vomiting, independently of any effect arising from the mere quantity of matter introduced into the stomach, or of any nauseous taste or flavour.

The susceptibility of vomiting is very different in different individuals, and is often considerably varied by disease.

Emetics are employed in many diseases.

When any morbid affection depends upon, or is connected with over distension of the stomach, or the presence of acrid, indigestible matters, vomiting gives speedy relief. Hence its utility in impaired appetite, acidity in the stomach, in intoxication, and where poisons have been swallowed.

From the pressure of the abdominal viscera in vomiting, emetics have been considered as serviceable in jaundice, arising from biliary calculi obstructing the ducts.

The expectorant power of emetics, and their utility in catarrh and phthisis, have been ascribed to a similar pressure extended to the thoracic viscera.

In the different varieties of febrile affections, much advantage is derived from exciting vomiting, especially in the very commencement of the disease. In high inflammatory fever it is considered as dangerous, and in the advanced stage of typhus it is prejudicial.

Emetics given in such doses, as only to excite nausea, have been found useful in restraining hæmorrhage.

Different species of dropsy have been cured by vomiting, from its having excited absorption. To the same effect, perhaps, is owing the dispersion of swelled testicle, bubo, and other swellings, which has occasionally resulted from this operation.

The operation of vomiting is dangerous, or hurtful, in the following cases: where there is determination of the blood to the head, especially in plethoric habits; in visceral inflammation; in the advanced stage of pregnancy; in hernia and prolapsus uteri; and wherever there exists extreme general debility. The frequent use of emetics weakens the tone of the stomach. An emetic should always be administered in the fluid form. Its operation may be promoted by drinking any tepid diluent, or bitter infusion.

The individual emetics may be arranged under two heads, those derived from the vegetable, and those from the mineral kingdom. From the vegetable kingdom are numbered ipecacuanha, scilla maritima, anthemis nobilis, sinapis alba, asarum Europæum, nicotiana tabacum. From the mineral kingdom, antimony, the sulphates of zinc and copper, and the subacetate of copper. To these may be added ammonia and its hydro-sulphuret.

Emetocatha'rticus. (From εμεω, to vomit, and καθαιρω, to purge.) Purging both by vomit and stool.

Emine'ntiæ quadrige'minæ. See *Tubercula quadrigemina*.

EMMENAGOGUES. (*Emmenagoga* sc. *medicamenta*, εμμηναγωγα: from εμμηνια, the menses, and αγω, to move.) Those medicines that possess a power of promoting that monthly discharge by the uterus, which, from a law of the animal œconomy, should take place in certain conditions of the female system. The articles belonging to this class may be referred to four orders:

1. *Stimulating emmenagogues*, as *hydrargyrite* and *antimonial preparations*, which are principally adapted for the young, and those with peculiar insensibility of the uterus.

2. *Irritating emmenagogues*, as *aloes*, *savine*, and *Spanish flies:* these are to be preferred in torpid and chlorotic habits.

3. *Tonic emmenagogues*, as *ferruginous preparations*, *cold bath*, and *exercise*, which are advantageously selected for the lax and phlegmatic.

4. *Antispasmodic emmenagogues*, as *assafœtida*, *castor*, and *pediluvia:* the constitutions to which these are more especially suited are the delicate, the weak, and the irritable.

Emme'nia. (From εν, in, and μην, a month.) The menstrual flux.

EMO'LLIENTS. (*Emollientia*, sc. *medicamenta:* from *emollio*, to soften.) Those substances which possess a power of relaxing the living and animal fibre, without producing that effect from any mechanical action. The different articles belonging to this class of medicines may be comprehended under the following orders:

1. *Humectant emollients*, as *warm water*, and *tepid vapours*, which are fitted for the robust and those in the prime of life.

2. *Relaxing emollients*, as *althæa*, *malva*, &c. These may be employed in all constitutions, while, at the same time, they do not claim a preference to others from any particular habit of body.

3. *Lubricating emollients*, as *bland oils*, *fat*, and *lard*. The same observation will hold of this order as was made of the last mentioned.

4. *Atonic emollients*, as *opium* and *pediluvia:* these are applicable to any constitution, but are to be preferred in habits where the effects of this class are required over the system in general.

Empei'ria. (From εν, and ϖειρω, to endeavour.) Professional experience.

Emphero'menus. (From εμφερω, to bear.) Urine, or other substance, which has a sediment.

Emphra'ctica. (From εμφραττω, to obstruct.) Medicines which, applied to the skin, shut up the pores.

EMPHYSE'MA. (From εμφυσαω, to inflate.) *Pneumatosis.* Air in the cellular membrane. In general it is confined to one place; but, in a few cases, it spreads universally over the whole body, and occasions a considerable degree of swelling. It sometimes arises spontaneously, which is, however, a very rare occurrence, or comes on immediately after delivery, without any evident cause; but it is most generally induced by some wound or injury done to the thorax, and which affects the lungs; in which case the air passes from these, through the wound, into the surrounding cellular membrane, and from thence spreads over the whole body.

Emphysema is attended with an evident crackling noise, and elasticity upon pressure; and sometimes with much difficulty of breathing, oppression, and anxiety.

We are to consider it as a disease by no means unattended with danger; but more probably from the causes which give rise to it, than any hazard from the complaint itself.

EMPIRIC. (*Empiricus*, εμπειρικος: from εν, in, and ϖειρα, experience.) One who practises the healing art upon experience, and not theory. This is the true meaning of the word empiric: but it is now applied, in a very opposite sense, to those who deviate from the line of conduct pursued by scientific and regular practitioners, and vend nostrums, or sound their own praise in the public papers.

Empla'stica. (From εμπλασσω, to obstruct.) Medicines which, spread upon the skin, stop the pores.

EMPLA'STRUM. (From εμπλασσω, to spread upon.) A plaster. Plasters are composed of unctuous substances, united either to powders or metallic oxides, &c. They ought to be of such a consistence as not to stick to the fingers when cold, but to become soft, so as to be spread out, in a moderate degree of heat, and in that of the human body, to continue tenacious enough to adhere to the skin. They owe their consistence either to metallic oxides, especially those of lead, or to wax, resin, &c. They are usually kept in rolls wrapped in paper, and spread, when wanted for use, upon thin leather; if the plaster be not of itself sufficiently adhesive, it is to be surrounded at its margin by a boundary of resin plaster.

Emplastrum ammoni'aci. Take of purified ammoniacum, five ounces; acetic acid, half a pint Dissolve the ammoniacum in the acid, then evaporate the liquor in an iron vessel, by means of a water-bath, constantly stirring it, until it requires a proper consistence. This plaster is now first introduced into the London Pharmacopœia; it adheres well to the skin, without irritating it, and without producing inconvenience by its smell.

EMPLASTRUM AMMONI′ACI CUM HYDRA′RGYRO. "Take of purified ammoniacum, a pound; purified mercury, three ounces; sulphurated oil, a fluid drachm." Rub the mercury with the sulphurated oil until the globules disappear; then add by degrees the ammoniacum, previously melted, and mix the whole together. This composition is said to possess resolvent virtues; and the plaster is recommended with this view to be applied to nodes, tophs, indurated glands, and tumours.

EMPLA′STRUM ASAFŒ′TIDÆ. *Emplastrum antihystericum.* Plaster of asafœtida. Take of plaster of semi-vitrified oxide of lead, asafœtida, each two parts; galbanum, yellow wax, each one part. This plaster is said to possess anodyne and antispasmodic virtues. It is, therefore, occasionally directed to be applied to the umbilical region in hysterical cases.

EMPLA′STRUM CANTHA′RIDIS. See *Emplastrum lyttæ.*

EMPLA′STRUM CE′RÆ. Wax plaster. *Emplastrum attrahens.* Take of yellow wax, prepared suet, of each three pounds; yellow resin, a pound. Melt them together and strain. This is a gently drawing preparation, calculated to promote a moderate discharge from the blistered surface, with which intention it is mostly used. Where the stronger preparations irritate, this will be found in general to agree.

EMPLA′STRUM CU′MINI. Cumin plaster. "Take of cumin-seeds, carraway-seeds, bay-berries, of each three ounces; dried pitch, three pounds; yellow wax, three ounces." Having melted the dried pitch and wax together, add the remaining articles previously powdered, and mix. A warm stomachic plaster, which, when applied to the stomach, expels flatulency. To indolent scrofulous tumours, where the object is to promote suppuration, this is an efficacious plaster.

EMPLA′STRUM GA′LBANI COMPO′SITUM. Compound Galbanum plaster, formerly called *emplastrum lithargyri compositum* and *diachylon magnum cum gummi.* Take of galbanum gum resin purified, eight ounces; lead plaster, three pounds; common turpentine, ten drachms; resin of the spruce fir, three ounces. Having melted the galbanum gum resin with the turpentine, mix in first the powdered resin of the spruce fir, and then the lead plaster, previously melted by a slow fire, and mix the whole. This plaster is used as a warm digestive and suppurative, calculated to promote maturation of indolent or scirrhous tumours, and to allay the pains of sciatica, arthrodynia, &c.

EMPLA′STRUM HYDRA′RGYRI. Mercurial plaster. *Emplastrum lithargyri cum hydrargyro.* "Take of purified mercury, three ounces; sulphurated oil, a fluid drachm; lead plaster, a pound." Rub the mercury with the sulphurated oil, until the globules disappear; then add by degrees the lead plaster, melted, and mix the whole.

EMPLA′STRUM LA′DANI COMPO′SITUM. Take of soft labdanum, three ounces; of frankincense, one ounce; cinnamon and expressed oil of mace, each half an ounce; essential oil of mint, one drachm: add to the frankincense, melted first, the labdanum a little heated, till it becomes soft, and then the oil of mace; afterwards mix in the cinnamon with the oil of mint, and beat them together into a mass, in a warm mortar, and keep it in a vessel well closed. This may be used with the same intentions as the cumin-plaster, to which it is in no way superior, though composed of more expensive materials. Formerly, it was considered as a very elegant stomach plaster, but is now disused.

EMPLASTRUM LITHA′RGYRI. See *Emplastrum plumbi.*

EMPLA′STRUM LITHA′RGYRI COMPO′SITUM. See *Emplastrum Galbani compositum.*

EMPLA′STRUM LITHA′RGYRI CUM RESI′NA. See *Emplastrum resinæ.*

EMPLA′STRUM LY′TTÆ. Blistering-fly plaster. *Emplastrum cantharidis. Emplastrum vesicatorium.* Take of blistering flies, in very fine powder, a pound; wax plaster, a pound and a half; prepared fat, a pound. Having melted the plaster and fat together, and removed them from the fire, a little before they become solid sprinkle in the blistering flies, and mix the whole together. See *Blister* and *Lyttæ.*

EMPLA′STRUM O′PII. Plaster of opium. "Take of hard opium, powdered, half an ounce; resin of the spruce fir, powdered, three ounces; lead plaster, a pound." Having melted the plaster, mix in the resin of the spruce fir and opium, and mix the whole. Opium is said to produce somewhat, though in a smaller degree, its specific effect when applied externally.

EMPLA′STRUM PI′CIS COMPO′SITUM. Compound pitch plaster. *Emplastrum picis Burgundicæ.* "Take of dried pitch, two pounds; resin of spruce fir, a pound; yellow resin, yellow wax, of each four ounces; expressed oil of nutmegs, an ounce." Having melted together the pitch, resin, and wax, add first the resin of the spruce fir, then the oil of nutmegs, and mix the whole together. From the slight degree of redness this stimulating application produces, it is adapted to gently irritate the skin, and thus relieve rheumatic pains. Applied to the temples, it is sometimes of use in pains of the head.

EMPLA′STRUM PLU′MBI. Lead plaster. *Emplastrum lithargyri. Emplastrum commune. Diachylon simplex.* "Take of semi-vitreous oxide of lead, in very fine powder, five pounds; olive oil, a gallon; water, two pints." Boil them with a slow fire, constantly stirring until the oil and litharge unite, so as to form a plaster. Excoriations of the skin, slight burns, and the like, may be covered with this plaster: but it is in more general use, as a defensive, where the skin becomes red from lying a long time on the part. This plaster is also of great importance, as forming the basis, by addition to which many other plasters are prepared.

Empla′strum resi′næ. Resin plaster. *Emplastrum adhæsivum. Emplastrum lithargyri cum resina.* "Take of yellow resin, half a pound; lead plaster, three pounds. Having melted the lead plaster over a slow fire, add the resin in powder, and mix." The adhesive, or sticking plaster, is chiefly used for keeping on other dressings, and for retaining the edges of recent wounds together.

Empla′strum sapo′nis. Soap plaster. Take of hard soap sliced, half a pound; lead plaster, three pounds. Having melted the plaster, mix in the soap; then boil it down to a proper consistence. Discutient properties are attributed to this elegant plaster, with which view it is applied to lymphatic and other indolent tumours. It forms an admirable defensive and soft application, spread on linen, to surround a fractured limb.

Empla′strum thu′ris compo′situm. Compound frankincense plaster. Take of frankincense, half a pound; dragon's blood, three ounces; litharge plaster, two pounds. To the melted lead plaster, add the rest powdered. This plaster is said to possess strengthening, as well as adhesive powers. By keeping the skin firm, it may give tone to the relaxed muscles it surrounds, but cannot, in any way, impart more strength than the common adhesive plaster.

Empneumato′sis. (From εν, in, and ϖνεω, to blow.) An inflation of the stomach, or any other viscus.

Empo′rium. (From εμπορεω, to negotiate.) A mart. The brain is so called, as being the place where all rational and sensitive transactions are collected.

E′mprion. (From εν, and ϖριων, a saw.) Serrated. An epithet of a pulse, in which the artery at different times is unequally distended.

EMPROSTHO′TONOS. (From εμπροσθεν, before, or forwards, and τεινω, to draw.) A clonic spasm of several muscles, so as to keep the body in a fixed position and bent forward. Cullen considers it as a species of tetanus. See *Tetanus.*

E′mptysis. (From εμπτυω, to spit out.) A discharge of blood from the mouth and fauces.

EMPYE′MA. (From εν, within, and ϖυον, pus.) A collection of pus in the cavity of the thorax. It is one of the terminations of pleuritis. There is reason for believing that matter is contained in the cavity of the chest, when, after a pleurisy, or inflammation in the thorax, the patient has a difficulty of breathing, particularly on lying on the side opposite the affected one; and when an œdematous swelling is externally perceptible.

Empye′mata. (From εν, and ϖυον, pus.) Suppurating medicines.

EMPYREU′MA. (From εμπυρευω, to kindle, from πυρ, fire.) The offensive smell that distilled waters and other substances receive from being exposed too much to fire.

EMPYREUMA′TIC. (*Empyreumatica*; from εμπυρευω, to kindle.) Smelling as it were burnt; thus empyreumatic oils are those distilled with a great heat, and impregnated with a smell of the fire.

EMU′LGENT. (*Emulgentia*; from *emulgeo*, to melt out; applied to the arteries and veins which go from the aorta and vena cava to the kidneys, because the antients supposed they strained, and, as it were, milked the serum through the kidneys.) The vessels of the kidneys are so termed. The emulgent artery is a branch of the aorta. The emulgent vein evacuates its blood into the ascending cava.

Emu′lsio amy′gdalæ commu′nis. Almond emulsion. Take of almonds, one ounce; water, two pounds and a half. Beat the blanched almonds in a stone mortar, gradually pouring on them the water; then strain off the liquor. It possesses cooling and demulcent properties.

Emu′lsio ara′bica. This is made in the same manner as the almond emulsion, only adding while beating the almonds, two ounces of gum arabic. This cooling and demulcent emulsion, ordered in the Edinburgh Pharmacopœia, may be drank ad libitum to mitigate ardor urinæ, whether from the venereal virus or any other cause. In difficult and painful micturition, and strangury, it is of infinite service.

Emu′lsio camphora′ta. "Take of camphor, one scruple; sweet almonds, blanched, two drachms; double refined sugar, one drachm; water, six ounces." This is to be made in the same manner as the common emulsion. It is calculated for the stomachs of those who can only bear small quantities of camphire.

EMU′LSION. (*Emulsio*; from *emulgeo*, to milk.) A soft and somewhat oily medicine, resembling milk.

Emulsion, almond. See *Emulsio amygdalæ communis.*

Emulsion, Arabic. See *Emulsio arabica.*

Emulsion, camphorated. See *Emulsio camphorata.*

Emulsion of asafœtida. See *Mistura asafœtidæ.*

Emulsion of gum-ammoniac. See *Mistura ammoniaci.*

EMU′NCTORY. (From *emungo*, to drain off.) The excretory ducts of the body are so termed; thus the exhaling arteries of the skin constitute the great emunctory of the body.

ENÆ′MA. (From *εν*, and *αιμα*, blood.) *Enæmos.* So Hippocrates and Galen call such topical medicines as are appropriated to bleeding wounds.

ENÆORE′MA. (From *εν*, and *αιωρεω*, to lift up.) The pendulous substance which floats in the middle of the urine.

ENA′MEL. See *Teeth.*

ENANTHE′SIS. (From *εν*, and *ανταω*, to meet.) The near approach of ascending and descending vessels.

ENARTHRO′SIS. (From *εν*, in, and *αρθρον*, a joint.) The ball and socket-joint. A species of diarthrosis, or moveable connection of bones, in which the round head of one is received into the deeper cavity of another, so as to admit of motion in every direction; as the head of the os femoris with the acetabulum of the os innominatum. See *Articulation.*

ENCA′NTHIS. (From *εν*, and *κανθος*, the angle of the eye.) A disease of the caruncula lachrymalis, of which there are two species. *Encanthis benigna*, and *Encanthis maligna seu inveterata.*

The encanthis, at its commencement, is nothing more than a small, soft, red, and sometimes rather livid excrescence, which grows from the caruncula lachrymalis, and, at the same time from the neighbouring semilunar fold of the conjunctiva. This excrescence on its first appearance, is commonly granulated, like a mulberry, or is of a ragged and fringed structure. Afterwards, when it has acquired a certain size, one part of it represents a granulated tumour, while the rest appears like a smooth, whitish, or ash-coloured substance, streaked with varicose vessels, sometimes advancing as far over the conjunctiva, covering the side of the eye next to the nose, as where the cornea and sclerotica unite.

The encanthis keeps up a chronic ophthalmy, impedes the action of the eyelids, and prevents, in particular, the complete closure of the eye. Besides, partly by compressing and partly by displacing the orifices of the puncta lachrymalia, it obstructs the free passage of the tears into the nose. The inveterate encanthis is ordinarily of a very considerable magnitude; its roots extend beyond the caruncula lachrymalis and semilunar fold to the membranous lining of one or both eyelids. The patient experiences very serious inconvenience from its origin and interposition between the commissure of the eyelids, which it necessarily keeps asunder on the side towards the nose. Sometimes the disease assumes a cancerous malignancy. This character is evinced by the dull red, and, as it were, leaden colour of the excrescence; by its exceeding hardness, and the lancinating pains which occur in it, and extend to the forehead, the whole eye-ball and the temple, especially when the tumour has been, though slightly, touched. It is also shewn, by the propensity of the excrescence to bleed, by the partial ulcerations on its surface, which emit a fungous substance, and a thin and exceedingly acrid discharge.

ENCATALE′PSIS. (From *εν*, and *καταλαμβανω*, to seize.) A catalepsy.

ENCATHI′SMA. (From *εν*, and *καθιζω*, to sit in.) A semicupium. A bath for half the body.

ENCAU′MA. (From *εν*, in, and *καιω*, to burn.) *Encausis.* A pustule produced from a burn.

ENCAU′SIS. (From *εν*, and *καιω*, to burn.) A burn or scald.

ENCEPHALOCE′LE. (From *εγκεφαλον*, the brain, and *κηλη*, a tumour.) A rupture of the brain.

ENCE′PHALON. (From *εν*, in, and *κεφαλη*, the head.) *Encephalum.* By some writers the cerebrum only is so called; and others express by this term the contents of the cranium.

ENCE′RIS. (From *εν*, and *κηρος*, wax.) A roll of wax for making plasters.

ENCERO′SIS. (From *εν*, and *κηροω*, to wax.) The covering of a plaster with wax.

ENCHARA′XIS. (From *εν*, and *χαρασσω*, to scarify.) A scarification.

ENCHEIRE′SIS. (From *εν*, and *χειρ*, the hand.) *Encheiria.* Galen uses this word as a part of the title to one of his works, which treats of dissection. The word imports the manual treatment of any subject.

ENCHEI′RIA. See *Encheiresis.*

ENCHILO′MA. See *Enchyloma.*

ENCHO′NDRUS. (From *εν*, and *χονδρος*, a cartilage.) A cartilage.

ENCHRI′STA. (From *εγχριω*, to anoint.) Unguents. Ointments.

ENCHYLO′MA. (From *εν*, and *χυλος*, juice.) An inspissated juice. An elixir, according to Lemery.

E′NCHYMA. (From *εν*, and *χεω*, to infuse.) An infusion. A sanguineous plethora.

ENCHY′MATA. (From *εγχυω*, to infuse.) Injections for the eyes and ears.

ENCHYMO′MA. (From *εν*, and *χυω*, to pour in.) In the writings of the antient physicians, it is a word by which they express that sudden effusion of blood into the cutaneous vessels, which arises from joy, anger, or shame; and in the last instance is what we usually call blushing.

ENCHYMO′SIS. (*Ἐγχυμωσις.*) Blushing; also an extravastation of blood, which makes the part appear livid. Thus, but improperly, it is synonymous with *Ecchymosis.*

E′NCHYSIS. See *Enchyma.*

ENCLY′SMA. (From *εν*, and *κλυζω*, to cleanse out.) A clyster.

ENCŒ′LIUM. (From *εν*, within, and *κοιλια*, the belly.) The abdominal viscera.

Encolpi′smus. (From εγκολπεω, to insinuate.) An uterine injection.

Encra′nium. (From εν, within, and κρανιον, the skull.) The cerebrum; the whole contents of the skull.

Encrasi′cholus. (From εν, in, κερας, the head, and χολη, bile; because it is said to have the gall in its head.) The anchovy.

E′ncris. Εγκρις. A cake of meal, oil, and honey.

E′ncymon. (From εν, and κυω, to conceive.) Pregnancy.

E′ncysis. (From εν, and κυω, to bring forth.) Parturition.

ENCY′STED. A term applied to those tumours which consist of a fluid or other matter, enclosed in a sac or cyst.

Ency′stis. (From εν, in, and κυστις, a bag.) A wen. A hard tumour.

ENDE′MIC. (*Endemicus*; from εν, in, and δημος, people.) A disease is so termed that is peculiar to a certain class of persons, or country; thus struma is endemial to the inhabitants of Derbyshire and the Alps; scurvy to seafaring people; and the plica polonica is met with in Poland.

E′ndesis. (From εν, and δεω, to tie up.) A ligature. A bandage.

Endive. See *Cichorium.*

ENDI′VIA. (*Quasi eundo viâ, quia passim nascitur*; named from the quickness of its growth.) See *Cichorium.*

E′ndosis. (From εν, and διδωμι, to give.) A remission, particularly of febrile disorders.

Enella′gmenus. (From εναλλαττω, to interchange.) An epithet applied to the union of the joints of the vertebræ.

E′NEMA. (*Enema, -matis*, neut. from ενιημι, to inject.) Injection. A clyster. A well-known form of conveying both nourishment and medicine to the system, under certain morbid circumstances. The former takes place where obstruction of the passage to the stomach is so great as to render access to that organ impossible, such as occurs in lock-jaw, diseased œsophagus, &c. By these means the body can be supported for a few weeks, while an attempt is made at effecting a cure. It is composed, in such cases, of animal broths, gruels made of farinaceous seeds, mucilages, &c. As a form of medicine, clysters are no less useful; and, according to the intention with which they are prescribed, they are either of an emollient, anodyne, or purgative nature. The following forms are in general use.

E′nema ano′dynum. Take of starch jelly, half a pint; tincture of opium, forty to sixty drops. Mix. The whole to be injected by means of a pewter clyster-syringe, in cases of dysentery or violent purging, and pain in the bowels.

E′nema antispasmo′dicum. Take of tinct. of assafœtida, half an ounce; tincture of opium, forty drops, gruel, half a pint. Mix. For spasmodic affections of the bowels.

E′nema laxati′vum. Take of Epsom salt, two ounces; dissolve in three quarters of a pint of warm gruel, or broth, with an ounce of fresh butter, or sweet oil.

E′nema nicotia′næ. Take of the infusion of tobacco from a half to a whole pint. Employed in cases of strangulated hernia

E′nema nu′triens. Take of strong beef tea, twelve ounces; thicken with hartshorn shavings, or arrow root.

E′nema Terebi′nthinæ. Take of common turpentine, half an ounce; the yolk of one egg, and half a pint of gruel. The turpentine being first incorporated with the egg, add to them the gruel. This clyster is generally used, and with great good effect, in violent fits of the stone.

Enerei′sis. (From ενερειδω, to adhere to.) A compression. A tight ligature.

E′NERGY. (*Energia*; from ενεργεω, to act.) Action. The degree of force exercised by any power: thus, nervous energy, muscular energy, &c.

Eneure′sis. See *Enuresis.*

Engala′ctum. (From εν, and γαλα, milk; so called because it is eaten by nurses to increase their milk.) The herb saltwort.

Engastrimy′thus. (From εν, in, γαστηρ, the belly, and μυθεομαι, to discourse.) A ventriloquist; one who appears to speak from his belly.

Engiso′ma. (From εγγιζω, to approach.) *Camarosis.* An instrument for making the parts of the broken clavicle meet. Also a fracture of the cranium.

English Mercury. See *Mercurialis.*

Englotto-ga′stor. (From εν, γλωττη, the tongue, and γαστηρ, the belly.) A ventriloquist.

Engompho′sis. (From εν, and γομφος, a nail.) That species of articulation which resembles a nail, driven into wood, as a tooth in its socket.

Engo′nios. (From εν, and γωνια, an angle.) The flexure, or angle made by the bending of a joint.

Enixum Parace′lsi. The caput mortuum of the distillation of nitric acid, or supersulphate of potash.

Enneapha′rmacum. (From εννεα, nine, and φαρμακον, a medicine) A medicine composed of nine simple ingredients.

Enneaphy′llum. (From εννεα, nine, and φυλλον, a leaf; because its flower consists of nine leaves.) A name for hellebo-raster, or bear's foot.

Enry′thmus. (From εν, and ῥυθμος, number.) A pulse in some respect regular.

Ens ma′rtis. A name antiently given to the oxide of iron, which arises in sublimation, with twice its quantity of sal-ammoniac. Medical practice does not at present place this preparation in a higher rank of estimation than other oxydes of iron.

Ens pri′mum sola′re. Antimony.

Ens ve′neris. The ens martis is in many dispensatories called by this name.

E′NSIFORM. (*Ensiformis*, sc. *cartilago;* from *ensis*, a sword, and *forma*, resemblance.) Sword-like. A term applied to a cartilage. See *Cartilago ensiformis.*

Ensta′ctum. (Fom εν, and σταζω, to instill.) A liquid medicine, which is applied stillatim, or drop by drop.

Enta′tica. (From εντεινω, to strain.) Provocatives: medicines which excite venereal inclination.

E′ntera. (From εντος, within.) The bowels. Hippocrates calls by this name the bags in which were formerly enclosed medicines for fomentations.

Enterade′nes. (From εντερον, an intestine, and αδην, a gland.) The intestinal glands.

Entere′nchyta. (From εντερα, the bowels, and εγχυω, to infuse into.) An instrument for administering clysters. A clyster-pipe.

ENTERI′TIS (Εντεριτις; from εντερον, an intestine.) Inflammation of the intestines. It is a genus of disease in the class *pyrexiæ*, and order *phlegmasiæ* of Cullen, and is known by the presence of pyrexia, fixed pain in the abdomen, costiveness, and vomiting. The causes of enteritis are much the same as those of gastritis, being occasioned by acrid substances, indurated fæces, long continued and obstinate costiveness, spasmodic colic, and a strangulation of any part of the intestinal canal; but another very general cause is the application of cold to the lower extremities, or to the belly itself. It is a disease which is most apt to occur at an advanced period of life, and is very liable to a relapse.

It comes on with an acute pain, extending in general over the whole of the abdomen; but more especially round the navel, accompanied with eructations, sickness at the stomach, a vomiting of bilious matter, obstinate costiveness, thirst, heat, great anxiety, and a quick and hard small pulse. After a short time, the pain becomes more severe, the bowels seem drawn together by a kind of spasm, the whole region of the abdomen is highly painful to the touch, and seems drawn together in lumpy contractions; invincible costiveness prevails, and the urine is voided with great difficulty and pain.

The inflammation continuing to proceed with violence, terminates at last in gangrene; or abating gradually, it goes off by resolution.

Enteritis is always attended with considerable danger, as it often terminates in gangrene in the space of a few hours from its commencement; which event is marked by the sudden remission of pain, sinking of the pulse, shrinking of the features, and distention of the belly; and it frequently proves fatal likewise, during the inflammatory stage. If the pains abate gradually, if natural stools be passed, if an universal sweat, attended with a firm equal pulse, comes on, or if a copious discharge of loaded urine, with the same kind of pulse, takes place, a resolution and favourable termination may be expected.

Dissections of this disease shew that the inflammation pervades the intestinal tube to a very considerable extent; that adhesions of the diseased portion to contiguous parts are formed; and that, in some cases, the intestines are in a gangrenous state, or that ulcerations have formed. They likewise shew that, besides obstinate obstructions, intrsusception, constrictions, and twistings, are often to be met with; and that, in most cases, the peritoneum is more or less affected, and is perceived, at times, to be covered with a layer of coagulable lymph. The treatment must be begun by taking blood freely from the arm, as far as the strength of the patient will allow: but the disease occurring more frequently in persons rather advanced in years, and of a constitution somewhat impaired, it becomes more important to limit this evacuation, and rely in a great measure on the effect of a number of leeches, applied to the abdomen. Another very useful step is to put the patient into a hot bath, which may presently induce faintness; or where this cannot be procured, fomenting the abdomen assidously. When the symptoms are thus materially relieved, an ample blister should be applied. It becomes also of the first importance to clear out the bowels: a copious laxative clyster will evacuate the inferior part of the canal, and solicit the peristaltic motion downwards; and the milder cathartics, as castor oil, neutral salts, &c. in divided doses, may gradually procure a passage. But where the disease has been preceded by costiveness, more active articles will probably be necessary, as calomel, compound extract of colocynth, infusion of senna, with salts, &c. If the stomach be irritable, the effervescing saline draught may enable it to retain the requisite cathartics. Another plan, often very successful, is giving opium in a full dose, particularly in conjunction with calomel, taking care to follow it up by some of the remedies above mentioned, till the bowels are relieved; which effect it appears to promote by its soothing antispasmodic power. Afterwards we may endeavour to keep up diaphoresis, and recruit the strength of the patient by a mild nourishing diet; taking care to guard against accumulation of fæces, exposure to cold, or any thing else likely to occasion a relapse.

ENTEROCE′LE. (From εντερον, an intestine, and κηλη, a tumour.) *Hernia intestinalis.* Every hernia may be so called that is produced by the protrusion of a portion of intestine, whether it is in the groin, navel, or elsewhere.

ENTERO-EPIPLOCE′LE. (From εντερον, an intestine, επιπλοον, the epiploon, and κηλη, a tumour.) A rupture formed by the protrusion of part of an intestine, with a portion of the epiploon.

ENTERO-HYDROCE′LE. (From εντερον, an intestine, υδωρ, water, and κηλη, a tumour.) This must mean a common scrotal hernia, with a good deal of water in the hernial sac; or else a hernia congenita, (in which the bowels descend into the tunica vaginalis testis,) attended with a collection of fluid in the cavity of this membrane.

ENTERO′MPHALUS. (From εντερον, an intestine, and ομφαλος, the navel.) An umbilical hernia, produced by the protrusion of a portion of intestine.

ENTERO′PHYTUM. (From εντερον, an intestine, and φυτον, a plant.) The sea-chitterling; a plant which grows in the form of a gut.

ENTERORA′PHIA. (From εντερον, an intestine, and ραφη, a suture.) A suture of the intestines, or the sewing together the divided edges of an intestine.

Enteroschеoce′le. (From εντερον, an intestine, οσχεον, the scrotum, and κηλη, a rupture.) *Hernia scrotalis*, or rupture of the intestines into the scrotum.

Enthe′mata. (From εντιθημι, to put in.) Anti-inflammatory styptics.

E′nthlasis. A contusion with the impression of the instrument by which it happened.

ENTRO′PIUM. (From εν, and τρεπω, to turn.) A disease of the eyelids, occasioned by the eyelashes and eyelid being inverted towards the bulb of the eye.

Entypo′sis. (From εντυποω, to make an impression.) The acetabulum, or concave bone of the shoulder.

E′NULA CAMPA′NA. (A corruption of *henula*, or *Helenium*, from *Helene*, the island where it grew.) See *Inula Helenium*.

Enu′lon. (From εν, and ουλον, the gums.) The internal flesh of the gums, or that part of them which is within the mouth.

ENURE′SIS. (From ενουρεω, to make water.) An incontinency or involuntary flow of urine. This disease usually proceeds either from relaxation or a paralytic affection of the sphincter of the bladder, induced by various debilitating causes, as too free a use of spirituous liquors, manustupration, and excess in venery; or it arises from compression on the bladder, from a diseased state of the organ, or from some irritating substance contained in its cavity. It is arranged in the class *locales*, and order *apocenoses* of Cullen, and contains two species: — 1. *Enuresis atonica*, the sphincter of the bladder having lost its tone from some previous disease: 2. *Enuresis ab irritatione, vel compressione vesicæ*, from an irritation or compression of the bladder.

Epacma′sticus. (From επι, and ακμαζω, to increase.) It is applied to fever which is still increasing in malignity.

Epa′cme. (From επακμαζω, to increase.) The increase, or exacerbation of a disease.

Epago′gium. (From επαγω, to draw over.) The præpuce, that part of the penis which is drawn over the glans, according to Dioscorides.

Epanadido′ntes. (From επαναδιδωμι, to increase.) A term applied to fevers which continue to increase in their degree of heat.

Epanadiplo′sis. (From επαναδιπλοω, to reduplicate.) The reduplication of a fit of a semitertian fever; that is, the return of the cold fit before the hot fit is ended.

Epana′stasis. (From επι, and ανιϛημι, to excite.) A tubercle, or small pustule upon the skin.

Epancylo′tus. (From επι, and αγκυλος, crooked.) A sort of crooked bandage in Oribasius.

Epa′rma. (From επαιρω, to elevate.) *Eparsis*. Any kind of tumour, but frequently applied to the parotis.

Epa′rsis. See *Eparma*.

Epasma′stica fe′bris. A fever is so called by Bellini, and others, while it is in its increase.

Epe′ncranis. (From επι, ἐν, in, and κρανιον, the skull.) The name of the cerebellum.

Ephebæ′um. (From επι, and ηϐη, the groin.) The hair upon the pubes.

E′phedra. (From εφεζομαι, to sit upon.) *Ephedrana*. The buttocks. Also a species of horse-tail.

Ephe′drana. See *Ephedra*.

Ephe′lcis. (From επι, upon, and ελκος, an ulcer.) The crust of an ulcer; hardened purulent expectoration.

EPHE′LIS. (From επι, and ηλιος, the sun.) A broad, solitary, or aggregated spot, attacking most commonly the face, back of the hand, and breast, from exposure to the sun.

EPHE′MERA. (From επι, upon, and ημερα, a day.) A fever which begins, is perfectly formed, and runs through its course in the space of twelve hours.

EPHEME′RIDES. (From εφημερις, an almanack; so called because, like the moon's age, they may be foretold by the almanack.) Diseases which return at particular times of the moon.

Ephia′ltes. (From εφαλλομαι, to leap upon; so called because it was thought a dæmon leaped upon the breast.) Incubus, or night-mare.

Ephia′ltia. (From *ephialtes*, the night-mare; so called because it was said to cure the night-mare.) The herb peony.

EPHIDRO′SIS. (From εφιδροω, to perspire.) *Sudatio*. *Mador*. A violent and morbid perspiration. A genus of disease in the class *locales*, and order *apocenoses* of Cullen.

EPHI′PPIUM. (A saddle, which it is thought to resemble.) See *Sella turcica.*

E′phodos. (From επι, and οδος, a way.) In Hippocrates it hath three significations: 1. The ducts or passages, by which the excrements of the body are evacuated. 2. The periodical attack of a fever, from the common use of it to express the attack of thieves. 3. The access of similar or dissimilar things, which may be useful or hurtful to the body.

Epia′ltes. See *Ephialtes.*

Epi′alus. (From ηπιον, gently, and αλεαζω, to heat.) *Epialos.* An ardent fever, in which both heat and cold are felt in the same part at the same time. Galen defines it to be a fever in which the patient labours under a preternatural heat and a coldness at the same time. The antient Latins call it *Quercera.*

Epi′bole. (From επιϐαλλω, to press upon.) The night-mare, or ephialtes.

Epica′nthis. (From επι, and κανθος, the angle of the eye.) The angle of the eye.

Epica′rpium. (From επι, upon, and καρπος, the wrist.) A topical medicine applied to the wrist.

Epica′uma. (From επι, and καιω, to burn.) *Encauma. Epicausis.* A burn, or scald.

Epicau′sis. See *Epicauma.*

Epi′ceras. (From επι, and κερας, a horn; so called because its pods are shaped like a horn.) The herb fænugreek.

Epicera′stica. (From επι, and κεραννυμι, to mix.) Medicines which, by mixing with acrimonious juices, temper them and render them less troublesome. Emollients.

Epicheire′sis. (From επι, and χειρ, the hand.) A manual operation.

Epi′cholus. (From επι, and χολη, the bile.) Bilious.

Epicho′rdis. (From επι, upon, and χορδη, a gut.) The mesentery.

Epicho′rios. (From επι, upon, and χορα, a region.) The same as epidermis.

Epicœ′lis. (From επι, upon, and κοιλις, the eyelid.) The upper eyelid.

Epico′lic. (*Epicolica;* from επι, upon, and κωλον, the colon.) Upon the colon. That part of the abdomen which lies over the head of the cœcum and the sigmoid flexure of the colon, called the epicolic region.

Epicopho′sis. (From επι, and κωφος, deaf.) A total deafness.

EPICRA′NIUM. (From επι, and κρανιον, the cranium.) The common integuments, aponeurosis, and muscular expansion which lie upon the cranium.

Epicra′nius. See *Occipito-frontalis.*

Epi′crasis. (From επι, and κεραννυμι, to temper.) A critical evacuation of bad humours, an attemperation of bad ones. When a cure is performed in the alterative way, it is called *per Epicrasin.*

Epi′crisis. (From επι, and κρινω, to judge from.) A judgment of the termination of a disease from present symptoms.

Epicte′nium. (From επι, about, and κλεις, the pubes.) The parts above and about the pubes.

Epicye′ma. (From επι, upon, and κυω, to conceive.) *Epicycsis.* Superfœtation. Superimpregnation.

Epicye′sis. See *Epicyema.*

EPIDE′MIC. (*Epidemicus;* from επι, upon, and δημος, the people.) A contagious disease is so termed, that attacks many people at the same season, and in the same place; thus putrid fever, plague, dysentery, &c. are often epidemic.

EPIDE′NDRUM. (From επι, upon, and δενδρον, a tree; because all this genus of plants grow parasitically on the trunk or branches of trees.) The name of a genus of plants in the Linnæan system. Class, *Gynandria.* Order, *Monandria.*

Epide′ndrum vani′lla. The systematic name of the vanelloe plant. *Vanilla. Banilia. Banilas. Aracus aromaticus.* The vanelloe is a long, flattish pod, containing, under a wrinkled brittle shell, a reddish brown pulp, with small shining black seeds. The plant which affords this fruit is the *Epidendrum vanilla; scandens, foliis ovato oblongis nervosis sessilibus caulinis, cirrhis spiralibus* of Linnæus. Vanelloes have an unctuous aromatic taste, and a fragrant smell like that of some of the finer balsams heightened with musk. Although chiefly used as perfumes, they are said to possess aphrodisiac virtues.

Epi′deris. (From επι, and δερας, the skin.) The clitoris.

EPIDE′RMIS. (From επι, upon, and δερμα, the true skin.) The scarf-skin. See *Cuticle.*

Epi′desis. (From επι, upon, and δεω, to bind.) A bandage to stop a discharge of blood.

Epide′smus. (From επι, upon, and δεω, to bind.) A bandage by which splints, bolsters, &c. are secured.

EPIDI′DYMIS. (From επι, upon, and διδυμος, a testicle.) A hard, vascular, oblong substance, that lies upon the testicle, formed of a convolution of the *vas deferens.* It has a thick end, which is convex, and situated posteriorly; and a thin end, which is rather flat, and situated inferiorly. The epididymis adheres to the testicle, by its two extremities only, for its middle part is free, forming a bag, to which the tunica vaginalis of the testicle is attached.

Epi′dosis. (From επιδιδωμι, to grow upon.) A preternatural enlargement of any part.

Epi′drome. (From επιδρεμω, to run upon.) An afflux of humours.

EPIGA′STRIC. (*Epigastricus,* επιγαστρικος; from επι, upon, or above, and γαστηρ, the stomach.) That part of the abdomen that lies over the stomach, is called the epigastric region; it reaches from the pit of the stomach to an imaginary line above the navel, supposed to be drawn from one extremity of the last of the false ribs to the other. Its sides are called hypochondria, and are covered by the false ribs, between which lies the epigastrium.

EPIGA'STRIUM. (From επι, upon, or above, and γαστηρ, the belly.) The region or part immediately over the stomach.

Epigenne'ma. (From επιγινομαι, to generate upon.) *Epigenesis.* The fur on the tongue. An accessory symptom.

Epigenne'sis. See *Epigennema.*

Epigino'mena. (From επιγινομαι, to succeed or supervene.) Galen says, they are those symptoms which naturally succeed, or may be expected in the progress of a disease; but Foësius says, they are accessions of some other affection to diseases, which never happen but in stubborn and malignant diseases.

Epiglo'ssum. (From επι, upon, and γλωσσα, the tongue; so called because a lesser leaf grows above the larger in the shape of a tongue.) The Alexandrian laurel.

EPIGLO'TTIS. (From επι, upon, and γλωττις, the tongue.) The cartilage at the root of the tongue that falls upon the glottis or superior opening of the larynx. Its figure is nearly oval; it is concave posteriorly, and convex anteriorly. Its apex or superior extremity is loose, and is always elevated upwards by its own elasticity. While the back of the tongue is drawn backwards in swallowing, the epiglottis is put over the aperture of the larynx, hence it shuts up the passage from the mouth into the larynx. The base of the epiglottis is fixed to the thyroid cartilage, the os hyoides, and the base of the tongue, by a strong ligament.

Epiglo'ttum. (From επιγλωττις, the epiglottis, which it resembles in shape.) An instrument mentioned by Paracelsus for elevating the eyelids.

Epiglou'tis. (From επι, upon, and γλουτος, the buttocks.) The superior parts of the buttocks.

Epigo'natis. (From επι, upon, and γονυ, the knee.) The patella or knee-pan.

Epigo'nides. (From επι, and γονυ, the knee.) The muscles inserted into the knees.

Epi'gonum. (From επιγινομαι, to proceed upon.) A superfœtation.

Epile'mpsis. See *Epilepsy.*

Epile'ntia. Corrupted from epilepsia.

EPILEPSY. (From επιλαμβανω, to seize upon; so called, from the suddenness of its attack.) It is also called falling sickness, from the patient suddenly falling to the ground on an attack of this disease. By the antients it was termed, from its affecting the mind, the most noble part of the rational creature, the sacred disease. It consists of convulsions with sleep, and usually froth issuing from the mouth. It is a genus of disease in the class *neuroses*, and order *spasmi* of Cullen, and contains three species: 1. *Epilepsia cerebralis;* attacking suddenly without manifest cause, and not preceded by any unpleasant sensation, unless perhaps some giddiness or dimness of sight. 2. *Epilepsia sympathica;* without manifest cause, but preceded by a sensation of an aura ascending from some part of the body to the head. 3. *Epilepsia occasionalis;* arising from manifest irritation, and ceasing on the removal of this. The last comprehends several varieties:

1. *Epilepsia traumatica,* arising from an injury of the head: 2. *Epilepsia à dolore,* from pain: 3. *Epilepsia verminosa,* from the irritation of worms: 4. *Epilepsia à veneno,* from poisons: 5. *Epilepsia exanthematica,* from the repulsion of cutaneous eruptions: 6. *Epilepsia à cruditate ventriculi,* from crudities of the stomach: 7. *Epilepsia ab inanitione,* from debility: 8. *Epilepsia uterina,* from hysterical affections: 9. *Epilepsia ex onanismo,* from onanism, &c.

Epilepsy attacks by fits, and after a certain duration goes off, leaving the person most commonly in his usual state; but sometimes a considerable degree of stupor and weakness remain behind, particularly where the disease has frequent recurrences. It is oftener met with among children than grown persons, and boys seem more subject to its attacks than girls. Its returns are periodical, and its paroxysms commence more frequently in the night than in the day, being somewhat connected with sleep. It is a disease sometimes counterfeited, in order to extort charity or excite compassion.

Epilepsy is properly distinguished into sympathic and idiopathic, being considered as sympathic, when produced by an affection in some other part of the body, such as acidities in the stomach, worms, teething, &c. as idiopathic when it is a primary disease, neither dependent on nor proceeding from any other.

The causes which give rise to epilepsy, are blows, wounds, fractures, and other injuries, done to the head by external violence, together with lodgments of water in the brain, tumours, concretions and polypi. Violent affections of the nervous system, sudden frights, fits of passion, great emotions of the mind, acute pains in any part, worms in the stomach or intestines, teething, the suppression of long accustomed evacuations, too great emptiness or repletion, and poisons received into the body, are causes which likewise produce epilepsy. Sometimes it is hereditary, and at others it depends on a predisposition arising from a mobility of the sensorium, which is occasioned either by plethora, or a state of debility.

An attack of epilepsy is now and then preceded by a heavy pain in the head, dimness of sight, noise in the ears, palpitations, flatulency in the stomach and intestines, weariness, and a small degree of stupor, and in some cases, there prevails a sense of something like a cold vapour or aura arising up to the head; but it more generally happens that the patient falls down suddenly without much previous notice; his eyes are distorted or turned so that only the whites of them can be seen; his fingers are closely clinched, and the trunk of his body particularly, on one side, is much agitated; he foams at the mouth, and thrusts out his tongue, which often suffers great injury from the muscles of the lower jaw being affected; he loses all sense of feeling, and not unfrequently voids both urine and fæces involuntarily.

The spasms abating he recovers gradually; but on coming to himself feels very languid and exhausted, and retains not the smallest recollection of what has passed during the fit.

When the disease arises from an hereditary disposition, or comes on after the age of puberty, or where the fits recur frequently, and are of long duration, it will be very difficult to effect a cure: but when its attacks are at an early age, and occasioned by worms, or any accidental cause, it may in general be removed with ease. In some cases, it has been entirely carried off by the occurrence of a fever, or by the appearance of a cutaneous eruption. It has been known to terminate in apoplexy, and in some instances to produce a loss of the powers of the mind, and to bring on idiotism.

The appearances usually to be observed on dissection, are serous and sanguineous effusion, a turgid tense state of the vessels of the brain without any effusion, a dilatation of some particular part of the brain, excrescences, polypi, and hydatids adhering to it, and obstructing its functions, and likewise ulcerations.

During the epileptic paroxysm in general, little or nothing is to be done, except using precautions, that the patient may not injure himself; and it will be prudent to remove any thing which may compress the veins of the neck, to obviate congestion in the head. Should there be a considerable determination of blood to this part, or the patient very plethoric, it may be proper, if you can keep him steady, to open a vein, or the temporal artery; and in weakly constitutions the most powerful antispasmodics might be tried in the form of clyster, as they could hardly be swallowed: but there is very seldom time for such measures. In the intervals the treatment consists: 1. In obviating the several exciting causes: 2. In correcting any observable predisposition: 3. In the use of those means, which are most likely to break through the habit of recurrence.

I. The manner of fulfilling the first indication requires little explanation: after an injury to the head, or where there is disease of the bone, an operation may be necessary, to remove irritation from the brain; in children teething, the gums ought to be lanced: where the bowels are foul or worms suspected, active purgatives should be exhibited, &c. In those instances, in which the aura epileptica is perceived, it has been recommended to destroy the part, where it originates, or divide the nerve going to it, or correct the morbid action by a blister, &c.; such means would certainly be proper when there is any disease discoverable in it. Making a tight ligature on the limb above has sometimes prevented a fit; but perhaps only through the medium of the imagination.

II. Where a plethoric state appears to lay the foundation of the disease, which is often the case, the patient must be restricted to a low diet, frequent purges exhibited, and the other excretions kept up, and he should take regular moderate exercise, avoiding whatever may determine the blood to the head; and to counteract such a tendency, occasional cupping, blisters, issues, &c. may be useful, as well as the shower bath; but in urgent circumstances, the lancet ought to be freely used. If on the contrary, there are marks of inanition and debility, a generous diet, with tonic medicines, and other means of strengthening the system, will be proper. The vegetable tonics have not been so successful in this disease as the metallic preparations, particularly the sulphate of zinc, the nitrate of silver, and the ammoniated copper, but this cannot perhaps be so safely persevered in; where the patient is remarkably exsanguious, chalybeates may answer better; and in obstinate cases the arsenical solution might have a cautious trial. In irritable constitutions sedatives are indicated, as digitalis, opium, &c.: but the free use of opium is restricted by a tendency to congestion in the head. Where syphilis appears to be concerned, a course of mercury is proper; in scrophulous habits, bark, with soda and sea-bathing; and so on.

III. The third division of remedies comes especially in use, where the fits are frequent, or where their recurrence can be anticipated: emetics will often prevent them, or a full dose of opium; also other powerful antispasmodics, as æther, musk, valerian, &c.: or strong odours, and in short any thing producing a considerable impression on the system. Bark taken largely might perhaps be more successful on this principle. The disease has sometimes been cured, especially when originating from sympathy, by inspiring fear or horror; and many frivolous charms may no doubt have taken effect through the medium of the imagination.

Also long voyages have removed it, which might especially be hoped for at the age of puberty, particularly if a considerable change in the mode of life were made in other respects; those who had lived indolently being obliged to exert themselves, the diet properly adapted to the state of the system, &c.

EPILO′BIUM. (From επι λοβου ιον, a violet or beautiful flower, growing on a pod.) The name of a genus of plants in the Linnæan system. Class, *Octandria*. Order, *Monogynia*.

Epilo′bium angustifo′lium. Rose-bay-willow herb. The young tender shoots cut in the spring, and dressed as asparagus, are little inferior to it.

Epime′dium. The plant barren-wort.

Epimo′rius. (From επι, and μειρω, to divide.) A term applied to an unequal pulse.

Epimy′lis. (From επι, and μυλη, the knee.) The patella or knee bone.

Epineneu′cus. (From επινευω, to nod or incline.) An unequal pulse.

Epino′tium. (From επι, upon, and νωτος, the back.) The shoulder blade.

Epiny′ctis. (From επι, and νυξ, night.) A pustule, which rises in the night, forming an angry tumour on the skin of the arms, hands, and thighs, of the size of a lupine, of a dusky red, and sometimes of a livid and pale colour, with great inflammation and pain. In a few days it breaks, and sloughs away.

Epipa′ctis. (From επιπακτοω, to coagulate.) A plant mentioned by Dioscorides; and so named because its juice was said to coagulate milk.

Epiparoxy′smus. (From επι, upon, and παροξυσμος, a paroxysm.) An unusual frequency of febrile exacerbation.

Epipa′stum. (From επι, upon, and πασσω, to sprinkle.) Any powdered drug sprinkled on the body.

Epipe′chys. (From επι, above, and πηχυς, the cubit.) That part of the arm above the cubit.

Epiphlogi′sma. (From επι, upon, and φλογιζω, to inflame.) Violent inflammation, or burning heat in any part, attended with pain, tumour, and redness: also a name given by Hippocrates to the shingles.

EPI′PHURA. (From επιφερω, to carry forcibly.) The watery eye. An involuntary flow of tears. A superabundant flowing of a serous or aqueous humour from the eyes. A genus of disease in the class *locales*, and order *apocenoses*, of Cullen. The humour which flows very copiously from the eye, in epiphora, appears to be furnished, not only by the lachrymal gland, but from the whole surface of the conjunctive membrane, Meibomius's glands, and the caruncula lachrymalis; which increased and morbid secretion may be induced from any stimulus seated between the globe of the eye and lids, as sand, acrid fumes, and the like; or it may arise from the stimulus of active inflammation; or from the acrimony of scrophula, measles, small pox, &c. or from general relaxation. The disease may also arise from a more copious secretion of tears, than the puncta lachrymalia can absorb, or as is most common, from an obstruction in the lachrymal canal, in consequence of which the tears are prevented from passing freely from the eye into the nose.

EPI′PHYSIS. (From επι, upon, and φυω, to grow.) Any portion of bone growing upon another, but separated from it by a cartilage.

Epipla′sma. (From επι, upon, and πλασσω, to spread.) A poultice; also a name for an application of wheat meal, boiled in hydrelæum, to wounds.

EPIPLOCE′LE. (From επιπλοον, the omentum, and κηλη, a tumour.) An omental hernia. A rupture produced by the protrusion of a portion of the omentum. See *Hernia*.

Epiplocomi′stes. (From επιπλοον, the omentum, and κομιζω, to carry.) One who has the omentum morbidly large.

Epipiloic appendages. See *Appendiculæ epiploicæ*.

EPIPLOI′TIS. (From επιπλοον, the omentum.) An inflammation of the process of the peritoneum, that forms the epiploon or omentum. See *Peritonitis*.

Epiploo′mphalon. (From επιπλοον, the omentum, and ομφαλος, the navel.) An omental hernia protruding at the navel.

EPI′PLOON. (From επιπλοω, to sail over, because it is mostly found floating, as it were, upon the intestines.) See *Omentum*.

EPIPLOSCHEOCE′LE. (From επιπλοον, the omentum, οσχεον, the scrotum, and κηλη, a tumour or hernia.) A rupture of the omentum into the scrotum, or a scrotal hernia containing omentum.

Epipo′lasis. (From επιπολαζω, to swim on the top.) A fluctuation of humours. A species of chemical sublimation.

Epipo′ma. (From επι, upon, and πωμα, a lid.) An instrument to cover the shoulder in a luxation.

Epiporo′ma. (From επιπωρεω, to harden.) An indurated tumour in the joints; a callous concretion, a tophus, a tophaceous callus molesting the joints.

Epipty′xis. (From επιπτυσσω, to close up.) A spasmodic closing of the lips.

Epipyre′xis. (From επι, and πυρεττω, to be feverish.) A rapid exacerbation in a fever.

Epirige′sis. (From επι, and ριγεω to become cold.) An unusual degree of cold, or repetition of rigors.

Epi′rrhoe. (From επι, upon, and ρεω, to flow.) An influx or afflux of humours to any part.

Episarci′dium. (From επι, upon, and

σαρξ, the flesh.) An anasarca, or dropsy spread between the skin and flesh.

EPISCHE'SIS. (From επισχεω, to restrain.) A suppression of excretions. It is an order in the class *locales* of Cullen's Nosology.

Epi'schium. (From επι, upon, and ισχιον, the hip-bone.) The os pubis.

Episcopa'lis. (From *episcopus*, a bishop, or mitred dignitary.) Resembling a bishop's mitre. It is applied to a valve at the orifice between the left auricle and ventricle of the heart called the mitral valve.

Epispa'smus. (From επισπαω, to draw together.) A quick inspiration of the breath.

EPISPA'STICS. (*Epispastica*, sc. *medicamenta*, from επισπαω, to draw together.) Those substances which are capable, when applied to the surface of the body, of producing a serous or puriform discharge, by exciting a previous state of inflammation. The term, though comprehending likewise issues and setons, is more commonly restricted to blisters — those applications which, exciting inflammation on the skin, occasion a thin serous fluid to be poured from the exhalants, raise the cuticle, and form the appearance of a vesicle. This effect arises from their strong stimulating power, and to this stimulant operation and the pain they excite, are to be ascribed the advantages derived from them in the treatment of disease. The evacuation they occasion is too inconsiderable to have any material effect.

It is a principle sufficiently established with regard to the living system, that where a morbid action exists, it may often be removed by inducing an action of a different kind in the same or neighbouring part. On this principle is explained the utility of blisters in local inflammation and spasmodic action, and it regulates their application in pneumonia, gastritis, hepatitis, phrenitis, angina, rheumatism, colic, and spasmodic affections of the stomach; diseases in which they are employed with the most marked advantage.

A similar principle exists with respect to pain; exciting one pain often relieves another. Hence blisters often give relief in tooth-ache, and some other painful affections.

Lastly, blisters, by their operation, communicate a stimulus to the whole system, and raise the vigour of the circulation. Hence, in part, their utility in fevers of the typhoid kind, though in such cases they are used with still more advantage to obviate or remove local inflammation

Episphæ'ria. (From επι, and σφαιρα, a sphere; so-called from the spherical shape of the brain.) The windings of the exterior surface of the brain; or the winding vessels upon it.

Epista'gmus. (From επι, and ϛαζω, to trickle down.) A catarrh.

Epistaphyli'nus. (From επι, and ϛαφυλη.) See *Uvula*.

EPISTA'XIS. (From επιϛαζω, to distil from.) Bleeding at the nose, with pain, or fulness of the head. A genus of disease arranged by Cullen in the class *pyrexiæ*, and order *hæmorrhagiæ*.

Persons of a sanguine and plethoric habit and not yet advanced to manhood, are very liable to be attacked with this complaint: females being much less subject to it than males, particularly after menstruation.

Epistaxis comes on at times without any previous warning; but at others, it is preceded by a pain and heaviness in the head, flushing in the face, heat and itching in the nostrils, a throbbing of the temporal arteries and a quickness of the pulse. In some instances a coldness of the feet, and shivering over the whole body, together with a costive belly, are observed to precede an attack of this hæmorrhage.

This complaint is to be considered as of little consequence, when occurring in young persons, being never attended with any danger; but when it arises in those who are advanced in life, flows profusely and returns frequently, it indicates too great fulness of the vessels of the head, and not unfrequently precedes apoplexy, palsy, &c. and, therefore, in such cases, is to be regarded as a dangerous disease. When this hæmorrhage arises in any putrid disorder, it is to be considered as a fatal symptom.

In general, we need not be very anxious to stop a discharge of blood from the nose, particularly where there are marks of fulness of the vessels of the head: but if it occurs under a debilitated state of the system, or becomes very profuse, means must be employed to suppress it. These are chiefly of a local nature; applying pressure to the bleeding vessels, introducing astringents into the nostrils, as solutions of alum, sulphate of zinc, sulphate of copper, &c. applying cold to the head, or to some very sensible part of the skin, as in the course of the spine, &c. At the same time the patient should be kept in the erect position. If the hæmorrhage be of an active character, the antiphlogistic regimen should be carefully observed: the patient kept cool and quiet; the saline cathartics, refrigerants, as nitrate of potash and the acids, digitalis, diaphoretics, &c. administered internally; and blood may be taken from the temples by leeches, or even from the arm, if the patient be very plethoric. Sometimes, after the failure of other means, closing the posterior as well as anterior outlets from the nose, and preventing the escape of the blood for some time mechanically, has been successful; and this might be particularly proper, where it was discharged copiously into the fauces, so as to endanger suffocation, on the patient falling asleep.

EPISTHO′TONOS. (From επιϛθεν, forwards, and τεινω, to extend.) A spasmodic affection of muscles drawing the body forwards. See *Tetanus*.

Episto′mion. (From επι, upon, and ϛομα, a mouth.) A stopper for a bottle. Also a vent-hole of a furnace, called the register.

Epistro′phalus. (From επι, upon, and ϛρεφω, to turn about.) It is applied to the first vertebra of the neck, because it turns about upon the second as upon an axis, which therefore was so called by the antients. Some, though improperly, called the second thus. It is also written *Epistrophea* and *Epistrophis*.

Epi′strophe. (From επιϛρεφω, to invert.) An inversion of any part, as when the neck is turned round. Also a return of a disorder which has ceased.

EPI′STROPHEUS. (From επιϛροφαω, to turn round, because the head is turned upon it.) *Epistrophæus*. The second cervical vertebra. See *Dentatus*.

Epi′strophis. See *Epistrophalus*.

Epi′tasis. (From επι, and τεινω, to extend.) The beginning and increase of a paroxysm or disease.

EPITHE′LIUM. The cuticle on the red part of the lips.

Epithe′ma. (From επι, upon, and τιθημι, to apply.) A term sometimes applied to a lotion, fomentation, or some external application.

Epithema′tium. The same. A plaster.

Epi′thesis. (From επι, and τιθημι, to cover, or lay upon.) The rectification of crooked limbs by means of instruments.

EPITHY′MUM. (From επι, upon, and θυμος, the herb thyme.) See *Cuscuta Epithymum*.

Epo′de. (From επι, over, and ωδη, a song.) *Epodos*. The method of curing distempers by incantation.

Epom′is. (From επι, upon, and ωμος, the shoulder.) The acromion, or upper part of the shoulder.

Epompha′lium. (From επι, upon, and ομφαλος, the navel.) An application to the navel.

EPSOM SALT. A purging salt formerly obtained by boiling down the mineral water found in the vicinity of Epsom in Surrey. It is at present prepared from sea water, which, after being boiled down, and the muriate of soda separated, deposits numerous crystals, that consist chiefly of sulphate of magnesia, and sold in the shops under the name of sal catharticus amarus, or bitter purging salt. See *Magnesiæ Sulphas*.

EPSOM WATER. *Aqua Epsomensis*. This water evaporated to dryness leaves a residuum, the quantity of which has been estimated from an ounce and a half in the gallon, to five drachms and one scruple. Of the total residuum, by far the greater part, about four or five-sixths, is sulphate of magnesia mixed with a very few muriates, such as that of lime, and probably magnesia, which render it very deliquescent, and increase the bitterness of taste, till purified by repeated crystallizations. There is nothing sulphurous or metallic ever found in this spring. The diseases in which it is employed are similar to those in which we use Sedlitz water. There are many other of the simple saline springs that might be enumerated, all of which agree with that of Epsom, in containing a notable proportion of some purging salt, (which, for the most part, is either Epsom or Glauber's salt, or often a mixture of both,) such as Acton, Kilburne, Bagnigge Wells, Dog and Duck, St. George's Fields, &c.

EPU′LIS. (From επι, and ουλα, the gums.) A small tubercle on the gums. It is said sometimes to become cancerous.

EPULO′TICS. (*Epulotica*, sc. *medicamenta*; from επουλοω, to cicatrize.) A term given by surgeons to those applications which promote the formation of skin.

EQUISE′TUM. (From *equus*, a horse, and *seta*, a bristle: so named from its resemblance to a horse's tail.)

1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*. Order, *Filices*.

2. The pharmacopœial name of the *Cauda equina*. See *Hippuris vulgaris*.

Equise′tum arve′nse. See *Hippuris vulgaris*.

E′quus a′sinus. The systematic name of the animal called an ass; the female affords a light and nutritious milk.

Era′nthemus. (From ηρ, the spring, and ανθεμος, a flower; so called because it flowers in the spring.) A sort of chamomile.

ERASIS′TRATUS, a celebrated Greek physician, said to have been born in the island of Ceos, and to have been the most distinguished pupil of Chrysippus, of the Cnidian school. He was the first, in conjunction with Herophilus, to dissect human bodies, anatomy having been before studied only in brutes; but the Ptolemies having allowed them to examine malefactors, they were enabled to make many important discoveries. Celsus notices a very improbable report, that they opened the bodies of those persons alive, to observe the internal motions: they could hardly then have maintained, that the arteries and left ventricle, do not naturally contain blood, but air only. The works of Erasistratus, which were numerous, are lost; but, from the account of Galen, he appears to have very accurately described the brain, which he considered as the common sensorium; also the heart and large vessels; and pointed out the office of the liver and kidneys; but he supposed digestion performed by trituration. He imagined inflammation and fever to arise from the blood being forced through the minute veins into the corresponding arteries. He was averse from blood-letting, or the use of active medicines, but sometimes employed mild clysters; trusting, however, principally to abstinence, and proper exercise. Being tormented with an ulcer in the foot, at an extreme old age, he is said to have terminated his existence by poison.

Erate′va ma′rmelos. The fruit of this plant, a native of several parts of India, is about the size of an orange, and covered with a hard bony shell, containing a yellow viscous pulp, of a most agreeable flavour; this is scooped out, and being mixed with sugar and orange, is brought to the tables of the grandees in India, who eat it as a great delicacy. It is also esteemed as a sovereign remedy against dysentery.

Erebi′nthus. (Ερεϐινθος.) The vetch.

ERE′CTOR CLITO′RIDIS. First muscle of the clitoris of Douglas. *Ischio-cavernosus* of Winslow, and *Ischio-clitoridien* of Dumas. A muscle of the clitoris that draws it downwards and backwards, and serves to make the body of the clitoris more tense, by squeezing the blood into it from its crus. It arises from the tuberosity of the ischium, and is inserted into the clitoris.

ERE′CTOR PE′NIS. *Ischio-cavernosus* of Winslow, and *Ischio-caverneux* of Dumas. A muscle of the penis that drives the urine or semen forwards, and, by grasping the bulb of the urethra, pushes the blood towards the corpus cavernosum and the glans, and thus distends them. It arises from the tuberosity of the ischium, and is inserted into the sides of the cavernous substance of the penis.

ERETHI′SMUS. (From ερεθιζω, to excite or irritate.) Increased sensibility and irritability. It is variously applied by modern writers. Mr. Pearson has described a state of the constitution produced by mercury acting on it as a poison. He calls it the mercurial erethismus, and mentions that it is characterized, by great depression of strength, anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small, quick, sometimes intermitting pulse, occasional vomiting, a pale contracted countenance, a sense of coldness; but the tongue is seldom furred, nor are the vital and natural functions much disturbed. In this state any sudden exertion will sometimes prove fatal.

Ergaste′rium. (From εργον, work.) A laboratory; that part of the furnace in which is contained the matter to be acted upon.

ERI′CA. (From ερεικω, to break; so named from its fragility, or because it is broken into rods to make besoms of.) The name of a genus of plants in the Linnæan system. Class, *Octandria*. Order, *Monogynia*. Heath.

Erice′rum. (From ερεικη, heath.) A medicine in which heath is an ingredient.

Eri′gerum. (From ηρ, the spring, and γερων, old; so called, because in the spring it has a white blossom like the hair of an old man.) See *Senecio vulgaris*.

ERO′SION. (From *erodo*, to gnaw off.) *Erosio*. This word is very often used in the same sense as ulceration, viz. the formation of a breach or chasm in the substance of parts, by the action of the absorbents.

EROTIA′NUS, the author of a glossary, containing an explanation of the terms in Hippocrates, lived in the reign of Nero. The work was printed at Venice, in 1566; and also annexed to Foësius's Edition of Hippocrates.

Erotoma′nia. (From ερως, love, and μανια, madness.) That melancholy, or madness, which is the effect of love.

E′rpes. (From ερπω, to creep; so named from their gradually increasing in size.) The shingles, or herpes.

ERRA′TIC. (*Erraticus*, from *erro*, to wander.) Wandering. Irregular. A term occasionally applied to pains, or any disease which is not fixed, but moves from one part to another, as gout, rheumatism, &c.

E′RRHINE. (*Errhina*, sc. *medicamenta*: ερρινα, from εν, in, and ριν, the nose.) By errhines are to be understood those medicines which, when topically applied to the internal membrane of the nose, excite sneezing, and increase the secretion, independent of any mechanical irritation. The articles belonging to this class may be referred to two orders.

1. *Sternutatary errhines*, as *nicotiana*, *helleborus*, *euphorbium*, which are selected for the torpid, the vigorous, but not plethoric; and those to whom any degree of evacuation would not be hurtful.

2. *Evacuating errhines*, as *asarum*, &c. which are calculated for the phlegmatic and infirm.

E′rror lo′ci. Boerhaave is said to have introduced this term, from the opinion that the vessels were of different sizes, for the circulation of blood, lymph, and serum, and that when the larger sized globules were forced into the lesser vessels, they became obstructed, by an *error of place*. But this opinion does not appear to be well grounded.

Eru′ca. (From *erugo*, to make smooth, so named from the smoothness of its leaves; or from *uro*, to burn, because of its biting quality.) See *Brassica*.

Eru′ca sylve′stris. The wild rocket. *Brassica erucastrum* of Linnæus. See *Brassica*.

ERUPTION. A discolouration, or spots on the skin, as the eruption of small pox, measles, nettle-rash, &c.

ERUPTIVE DISEASES. A term nearly synonimous with cutaneous diseases.

Eruthe′ma. (From ερευθω, to make red.) A fiery red tumour, or pustules on the skin.

E′RVUM. (*Quasi arvum*, a field, because it grows wild in the fields: or from *eruo*, to pluck out, because it is diligently plucked from corn.) The tare.

1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia.* Order, *Decandria.*

2. The pharmacopœial name of tare. See *Ervum Ervilia.*

Er′vum er′vilia. *Orobus.* The plant ordered by this name is the *Ervum ervilia; germinibus undato plicatis, foliis imparipinnatis*, of Linnæus. In times of scarcity, the seeds have been made into bread, which is not the most salubrious. The meal was formerly amongst the resolvent remedies by way of poultice.

E′rvum lens. The systematic name of the lentil. *Lens*, φακος of the Greeks. *Ervum lens pedunculis subbifloris; seminibus compressis, convexis*, of Linnæus. There are two varieties; the one with large, the other small seeds. They are eaten in many places as we eat peas, than which they are more flatulent, and more difficult to digest. A decoction of these seeds is used as a lotion to the ulcerations after small-pox, and, it is said, with success.

ERY′NGIUM. (From ερυγγανω, to eructate.) Eryngo, or sea-holly.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Digynia.*

2. The pharmacopœial name of the sea holly. See *Eryngium maritimum.*

Eryngium maritimum. The systematic name of the sea holly or eryngo. *Eryngium:—foliis radicalibus subrotundis, plicatis spinosis, capitulis pedunculatis, paleis tricuspidatis*, of Linnæus. The root of this plant is directed for medicinal use. It has no particular smell, but to the taste it manifests a grateful sweetness; and, on being chewed for some time, it discovers a light aromatic warmth or pungency. It was formerly celebrated for its supposed aphrodisiac powers, but it is now very rarely employed.

Ery′ngium campe′stre. The root of this plant, *Eryngium campestre; foliis radicalibus, amplexicaulibus, pinnato-lanceolatis*, of Linnæus, is used in many places for that of the sea eryngo. See *Eryngium.*

Eryngo. See *Eryngium.*

Eryngo, sea. See *Eryngium.*

Eryngo leaved lichen. See *Lichen islandicus.*

ERY′SIMUM. (From ερυω, to draw, so called from its power of drawing and producing blisters; others derive it απο του ερεικειν, because the leaves are much cut; others from εριτιμον, precious.)

1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia.* Order, *Siliquosa.*

2. The pharmacopœial name of the hedge mustard. See *Erysimum officinale.*

Ery′simum allia′ria. The systematic name of Jack in the hedge. *Alliaria.* Sauce-alone, or stinking hedge-mustard. The plant to which this name is given, in the pharmacopœias, is the *Erysimum alliaria; foliis cordatis*, of Linnæus; it is sometimes exhibited in humid asthma and dyspnœa, with success. Its virtues are powerfully diaphoretic, diuretic, and antiscorbutic.

Ery′simum barbare′a. The systematic name of the barbarea of the shops. *Barbarea.* The leaves of this plant, *Erysimum barbarea:—foliis lyratis, extimo subrotundo* of Linnæus, may be ranked among the antiscorbutics. They are seldom used in practice.

Ery′simum officina′le. The systematic name of the hedge mustard. *Erysimum.* This plant; *Erysimum siliquis spicæ adpressis, foliis runcinatis*, of Linnæus, was formerly much used for its expectorant and diuretic qualities, which are now forgotten. The seeds are warm and pungent, and very similar to those of mustard in their sensible effects.

ERYSI′PELAS. (From ερυω, to draw, and πελας, adjoining; named from the neighbouring parts being affected by the eruption.) *Ignis sacer.* The rose, or St. Anthony's fire. A genus of disease in the class *pyrexiæ*, and order *exanthemata* of Cullen. It is known by synocha of two or three days continuance, with drowsiness, and sometimes with delirium; pulse commonly full and hard; then erythema of the face, or some other part, with continuance of synocha, tending either to abscess or gangrene. There are two species of this disease, according to Cullen: 1. *Erysipelas vesiculosum*, with large blisters: 2. *Erysipelas phlyctænodes*, the shingles, or an erypelas with phlyctænæ, or small blisters.

This disease is an inflammatory affection, principally of the skin, when it makes its appearance externally, and of the mucous membrane when it is seated internally; and is more liable to attack women and children, and those of an irritable habit, than those of a plethoric and robust constitution.

It is remarkable that erysipelas sometimes returns periodically, attacking the patient once or twice in the year, or even once every month, and then by its repeated attacks it often gradually exhausts the strength, especially if he be old and of a bad habit.

When the inflammation is principally confined to the skin, and is unattended by any affection of the system, it is then called erythema; but when the system is affected it is named erysipelas.

Every part of the body is equally liable to it, but it more frequently appears on the face, legs, and feet, than any where else when seated externally; and it occurs oftener in warm climates than phlegmonous inflammation.

It is brought on by all the causes that are apt to excite inflammation, such as injuries of all kinds, the external application of stimulants, exposure to cold, and obstructed perspiration; and it may likewise be occasioned by a certain matter generated within the body, and thrown out on its surface. A particular state of the atmosphere seems sometimes to render it epidemical.

In slight cases, where it attacks the extremities, it makes its appearance with a roughness, heat, pain, and redness of the skin, which becomes pale when the finger is pressed upon it, and again returns to its former colour, when it is removed, There prevails likewise a small febrile disposition, and the patient is rather hot and thirsty. If the attack is mild, these symptoms will continue only for a few days, the surface of the part affected will become yellow, the cuticle or scarf-skin will fall off in scales, and no further inconvenience will perhaps be experienced; but if the attack has been severe, and the inflammatory symptoms have run high, then there will ensue pains in the head and back, great heat, thirst, and restlessness; the part affected will slightly swell: the pulse will become small and frequent; and about the fourth day, a number of little vesicles, containing a limpid, and, in some cases, a yellowish fluid, will arise. In some instances, the fluid is viscid, and instead of running out, as generally happens when the blister is broken, it adheres to and dries upon the skin.

In unfavourable cases, these blisters sometimes degenerate into obstinate ulcers, which now and then become gangrenous. This, however, does not happen frequently; for although it is not uncommon for the surface of the skin, and the blistered places to appear livid or even blackish, yet this usually disappears with the other symptoms of the complaint.

The period at which the vesicles shew themselves is very uncertain. The same may be said of the duration of the eruption. In mild cases, it often disappears gradually, or is carried off by spontaneous sweating. In some cases it continues without shewing any disposition to decline for twelve or fourteen days, or longer.

The trunk of the body is sometimes attacked with erysipelatous inflammation, but less frequently so than the extremities. It is not uncommon, however, for infants to be attacked in this manner a few days after birth; and in these it makes its appearance about the genitals. The inflamed skin is hard, and apparently very painful to the touch. The belly often becomes uniformly tense, and sphacelated spots sometimes are to be observed. From dissections made by Dr. Underwood, it appears, that in this form of the disease the inflammation frequently spreads to the abdominal viscera.

Another species of erysipelatous inflammation, which most usually attacks the trunk of the body, is that vulgarly known by the name of *shingles*, being a corruption of the French word *ceingle*, which implies a belt. Instead of appearing an uniform inflamed surface, it consists of a number of little pimples extending round the body a little above the umbilicus, which have vesicles formed on them in a short time. Little or no danger ever attends this species of erysipelas.

When erysipelas attacks the face, it comes on with chilliness, succeeded by heat, restlessness, thirst, and other febrile symptoms, with a drowsiness or tendency to coma or delirium, and the pulse is very frequent and full. At the end of two or three days, a fiery redness appears on some part of the face, and this extends at length to the scalp, and then gradually down the neck, leaving a tumefaction in every part the redness has occupied. The whole face at length becomes turgid, and the eyelids are so much swelled as to deprive the patient of sight. When the redness and swelling have continued for some time, blisters of different sizes, containing a thin colourless acrid liquor, arise on different parts of the face, and the skin puts on a livid appearance in the blistered places; but in those not affected with blisters, the cuticle, towards the close of the disease, falls of in scales.

No remission of the fever takes place on the appearance of the inflammation on the face; but, on the contrary, it is increased as the latter extends, and both will continue probably for the space of eight or ten days. In the course of the inflammation, the disposition to coma and delirium are sometimes so increased as to destroy the patient between the seventh and eleventh days of the disease. When the complaint is mild, and not leading to a fatal event, the inflammation and fever generally cease gradually without any evident crisis.

If the disease arises in a bad habit of body, occupies a part possessed of great sensibility, is accompanied with much inflammation, fever, and delirium, and these take place at an early period, we may suppose the patient exposed to imminent danger. Where translations of the morbid matter take place, and the inflammation falls on either the brain, lungs, or abdominal viscera, we may entertain the same unfavourable opinion. Erysipelas never terminates in suppuration, unless combined with a considerable degree of phlegmonous inflammation, which is, however, sometimes the case; but in a bad habit, it is apt to terminate in gangrene, in which case there will be also great danger. When the febrile symptoms are mild, and unaccompanied by delirium or coma, and the inflammation does not run high, we need not be apprehensive of danger.

Where the disease has occupied the face, and proves fatal, inflammation of the brain, and its consequences, are to be met with on dissection.

The treatment of erysipelas must proceed on the antiphlogistic plan, varied however in its activity according to the type of the disease. When it occurs in robust plethoric constitutions, partaking of the phlegmonous character, with severe synochal fever, it will be proper to begin by taking a moderate quantity of blood; then direct cooling saline purgatives, antimonial diaphoretics, a light vegetable diet, &c. When the disorder attacks the face, it may be better to use cupping behind the neck, and keep the head somewhat raised. But if the disease exhibits rather the typhoid type, and particularly where there is a tendency to gangrene, the patient's strength must be supported: after clearing out the primæ viæ, and endeavouring to promote the other secretions by mild evacuants, when the pulse begins to fail, a more nutritious diet, with a moderate quantity of wine, and the decoction of bark with sulphuric acid, or other tonic medicine, may be resorted to; nay, even the bark in substance, and the more powerful stimulants, as ammonia, &c. ought to be tried, if the preceding fail. Should the inflammation, quitting the skin, attack an internal part, a blister, or some rubefacient, may help to relieve the patient; and stimulants to the lower extremities will likewise be proper, where the head is severely affected. To the inflamed part of the skin applications must not be too freely made: where there is much pain and heat, cooling it occasionally with plain water, is perhaps best; and where an acrid discharge occurs, washing it away from time to time with warm milk and water. Should suppuration happen, it is important to make an early opening for the escape of the matter, to obviate the extensive sloughings otherwise apt to follow, and where gangrene occurs, the fermenting cataplasm may be applied.

ERYTHE′MA. (From ερυθρος, red.) A morbid redness of the skin, as is observed upon the cheeks of hectic patients after eating, and the skin covering bubo, phlegmon, &c. Erysipelas is so called when the inflammation is principally confined to the skin.

ERYTHRO′DANUM. (From ερυθρος, red, so called from the colour of its juice.) See *Rubia*.

ERYTHROEI′DES. (From ερυθρος, red, and ειδος, a likeness, so called from its colour.) A name given to the tunica vaginalis testis.

ERYTHRO′NIUM. (From ερυθρος, red, so called from the red colour of its juice.) A species of satyrion.

ERYTHRO′XYLUM. (From ερυθρος, red, and ξυλον, wood, so named from its colour.) Logwood.

E′RYTHRUS. (From ερυθρος, red, so named from the red colour of its juice.) The herb stumach.

E′SAPHE. (From εσαφαω, to feel.) The touch; or feeling the mouth of the womb, to know its state.

E′SCHAR. (Εσχαρα, from εσχαροω, to scab over.) *Eschara*. The portion of flesh that is destroyed by the application of a caustic.

ESCHARO′TICS. (*Escharotica*, sc. *medicamenta*, εσχαρωτικα, from εσχαροω, to scab over.) Caustics. Corrosives. A term given by surgeons to those substances which possess a power of destroying the texture of the various solid parts of the animal body to which they are directly applied. The articles of this class of substances may be arranged under two orders.

1. *Eroding escharotics*, as blue vitriol, alumen ustum, &c.

2. *Caustic escharotics*, as *lapis infernalis, argentum nitratum, oleum vitrioli, acidum nitrosum*, &c.

ESCULENT. An appellation given to such plants, or any part of them, that may be eaten for food.

E′SOX LU′CIUS. The systematic name of a fish of the class *pisces*, and order *abdominales*, from whose liver an oil spontaneously is separated, which is termed in some pharmacopœias *oleum lucii piscis*. It is used in some countries by surgeons, to destroy spots of the transparent cornea.

E′SSENCE. Several of the volatile or essential oils are so called by the perfumers.

ESSE′NTIAL OIL. See *Oil*.

E′SSERA. (Arab. A humour.) A species of cutaneous eruption, distinguished by broad, shining, smooth, red spots, mostly without fever, and differing from the nettle rash in not being elevated. It generally attacks the face and hands.

E′SULA. (From *esus*, eaten, because it is eaten by some as a medicine.) Spurge.

E′SULA MA′JOR. See *Euphorbia palustris*.

E′SULA MI′NOR. See *Euphorbia cyparissias*.

E′THER. See *Æther*.

E′THER, ACE′TIC. Acetic naphtha. An etherial fluid, drawn over from an equal admixture of alkohol and acetic acid, distilled with a gentle heat from a glass resort in a sand-bath. It has a grateful smell, is extremely light, volatile, and inflammable.

E′THER, MURIA′TIC. Marine ether. Marine ether is obtained by mixing and distilling alkohol with extremely concentrated muriate of tin. It is stimulant, antiseptic, and diuretic.

E′THER, NI′TROUS. Nitric naphtha. This is only a stronger preparation than the spiritus ætheris nitrici of the London Pharmacopœia; it is produced by the distillation of two parts of alkohol to one part and an half of fuming nitric acid.

E'THER, SULPHU'RIC. See *Æther sulphuricus.*

E'THER, VITRIO'LIC. See *Æther sulphuricus.*

ETHE'RIAL OIL. Any highly rectified essential oil may be so termed. See *Oleum Æthereum.*

E'thiops, antimónial. See *Æthiops antimonialis.*

E'thiops, míneral. See *Hydrargyri sulphuretum nigrum.*

E'thiops per se. See *Hydrargyri oxydum cinereum.*

ETHMOI'DES. See *Ethmoid bone.*

ETHMOID BONE. (*Os ethmoides;* from εθμος, a sieve, and ειδος, form; because it is perforated like a sieve.) *Os ethmoideum. Os æthmoides.* Cribriform bone. A bone of the head. This is, perhaps, one of the most curious bones of the human body. It appears almost a cube, not of solid bone, but exceedingly light, spongy, and consisting of many convoluted plates, which form a net-work, like honey-comb. It is curiously enclosed in the os frontis, betwixt the orbitary processes of that bone. One horizontal plate receives the olfactory nerves, which perforate that plate with such a number of small holes, that it resembles a sieve; whence the bone is named cribriform, or ethmoid bone. Other plates dropping perpendicularly from this one, receive the divided nerves, and give them an opportunity of expanding into the organ of smelling; and these bones, upon which the olfactory nerves are spread out, are so much convoluted as to extend the surface of this sense very greatly, and are named spongy bones. Another flat plate lies in the orbit of the eye; and being very smooth, by the rolling of the eye it is named the os planum, or smooth bone. So that the ethmoid bone supports the fore-part of the brain, receives the olfactory nerves, forms the organ of smelling, and makes a chief part of the orbit of the eye; and the spongy bones, and the os planum, are neither of them distinct bones, but parts of this ethmoid bone.

The *cribriform plate* is exceedingly delicate and thin; lies horizontally over the root of the nose; and fills up neatly the space betwixt the two orbitary plates of the frontal bone. The olfactory nerves, like two small flat lobes, lie out upon this plate, and, adhering to it, shoot down like many roots through this bone, so as to perforate it with numerous small holes, as if it had been dotted with the point of a pin, or like a nutmeg-grater. This plate is horizontal; but its processes are perpendicular, one above, and three below.

1. The first perpendicular process is what is called *crista galli;* a small perpendicular projection, somewhat like a cock's comb, but exceedingly small, standing directly upwards from the middle of the cribriform plate, and dividing that plate into two; so that one olfactory nerve lies upon each side of the crista galli; and the root of the falx, or septum, betwixt the two hemispheres of the brain, begins from this process. The foramen cæcum, or blind hole of the frontal bone, is formed partly by the root of the crista galli, which is very smooth, and sometimes, it is said, hollow, or cellular.

2. Exactly opposite this, and in the same direction with it, *i. e.* perpendicular to the ethmoid plate, stands out the *nasal plate* of the ethmoid bone. It is sometimes called azygous, or single process of the ethmoid, and forms the beginning of that septum, or partition, which divides the two nostrils. This process is thin but firm, and composed of solid bone; it is commonly inclined a little to one side, so as to make the nostrils of unequal size. The azygous process is united with the vomer, which forms the chief part of the partition; so that the septum, or partition of the nose, consists of the azygous process of the ethmoid bone above, of the vomer below, and of the cartilage in the fore or projecting part of the nose; but the cartilage rots away, so that whatever is seen of the septum in the skull, must be part either of the ethmoid bone or vomer.

3. Upon either side of the septum, there hangs down a *spongy bone,* one hanging in each nostril. They are each rolled up like a scroll of parchment; they are very spongy; are covered with a delicate and sensible membrane: and when the olfactory nerves depart from the cribriform plate of the ethmoid bone, they attach themselves to the septum, and to these upper spongy bones, and expand upon them so that the convolutions of these bones are of material use in expanding the organ of smelling, and detaining the odorous effluvia till the impression be perfect. Their convolutions are more numerous in the lower animals, in proportion as they need a more acute sense. They are named spongy or turbinated bones, from their convolutions resembling the many folds of a turban.

The spongy bones have a great many honey-comb-like cells connected with them, which belong also to the organ of smell, and which are useful perhaps by detaining the effluvia of odorous bodies, and also by reverberating the voice. Thus, in a common cold, while the voice is hurt by an affection of these cells, the sense of smelling is almost lost.

4. The *orbitary plate,* of the ethmoid bone, is a large surface; consisting of a very firm plate of bone, of a regular square form: exceedingly smooth and polished;

it forms a great part of the socket for the eye, lying on its inner side. When we see it in the detached bone, we know it to be just the flat side of the ethmoid bone; but while it is incased in the socket of the eye, we should believe it to be a small square bone: and from this, and from its smoothness, it has got the distinct name of os planum.

The cells of the ethmoid bone, which form so important a share of the organ of smell, are arranged in great numbers along the spongy bone. They are small neat cells, much like a honey-comb, and regularly arranged in two rows, parted from each other by a thin partition; so that the os planum seems to have one set of cells attached to it, while another regular set of cells belongs in like manner to the spongy bones. There are thus twelve in number opening into each other, and into the nose.

These cells are frequently the seat of venereal ulcers; and the spongy bones are the surface where polypi often sprout up. And from the general connections and forms of the bone, we can easily understand how the venereal ulcer, when deep in the nose, having got to these cells, cannot be cured, but undermines all the face; how the venereal disease, having affected the nose, soon spreads to the eye, and how even the brain itself is not safe. We see the danger of a blow upon the nose, which, by a force upon the septum, or middle partition, may depress the delicate cribriform plate, so as to oppress the brain with all the effects of a fractured skull, and without any operation which can give relief. And we also see the danger of pulling away polypi, which are firmly attached to the upper spongy bone.

ETMULLER, Michael, was born at Leipsic in 1644. He graduated there at the age of twenty-four, after going through the requisite studies, and much improving himself by travelling through different parts of Europe. Eight years after he was appointed professor of Botany in that University, as well as extraordinary professor of surgery and anatomy. He fulfilled those offices with great applause, and his death, which happened in 1683, was generally regretted by the faculty of Leipsic. He was a very voluminous writer, and his works were considered to have sufficient merit to be translated into most European languages.

E′tron. (From εδω, to eat, as containing the receptacles of the food.) The hypogastrium.

Eua′nthemum. (From ευ, well, and ανθεμος, a flower; so named from the beauty of its flowers.) The chamomile.

Eua′phium. (From ευ, well, and αφη, the touch; so called because its touch was supposed to give ease.) A medicine for the piles.

EUDIOMETER. An instrument by which the quantity of oxygen and nitrogen in atmospherical air can be ascertained. Several methods have been employed, all founded upon the principle of decomposing common air by means of a body which has a greater affinity for the oxygen. See *Eudiometry*.

EUDIOMETRY. The method of ascertaining the purity of atmospheric air.

No sooner was the composition of the atmosphere known, than it became an inquiry of importance to find out a method of ascertaining, with facility and precision, the relative quantity of oxygen gas contained in a given bulk of atmospheric air.

The instruments in which the oxygen gas of a determined quantity of air was ascertained, received the name of *Eudiometers*, because they were considered as measurers of the purity of air. They are, however, more properly called *Oximeters*.

The eudiometers proposed by different chemists, are the following:

1. *Priestley's Eudiometer*.

The first eudiometer was made in consequence of Dr. Priestley's discovery, that when nitrous gas is mixed with atmospheric air over water, the bulk of the mixture diminishes rapidly, in consequence of the combination of the gas with the oxygen of the air, and the absorption of the nitric acid thus formed by the water.

When nitrous gas is mixed with nitrogen gas, no diminution takes place; but when it is mixed with oxygen gas, in proper proportions, the absorption is complete. Hence it is evident, that in all cases of a mixture of these two gases, the diminution will be proportional to the quantity of the oxygen. Of course it will indicate the proportion of oxygen in air; and, by mixing it with different portions of air, it will indicate the different quantities of oxygen which they contain, provided the component parts of air be susceptible of variation.

Dr. Priestley's method was to mix together equal bulks of air and nitrous gas in a low jar, and then transfer the mixture into a narrow graduated glass tube about three feet long, in order to measure the diminution of bulk. He expressed this diminution by the number of hundredth parts remaining. Thus, suppose he had mixed together equal parts of nitrous gas and air, and that the sum total was 200 (or 2.00): suppose the residuum, when measured in the graduated tube, to amount to 104 (or 1.04), and of course that 96 parts of the whole had disappeared, he denoted the purity of the air thus tried by 104.

This method of analyzing air by means of nitrous gas is liable to many errors. For the water over which the experiment is made may contain more or less carbonic acid, atmospheric air, or other heterogeneous substance. The nitrous gas is not always of the same purity, and is partly absorbed by the nitrous acid which is formed; the figure of the vessel, and many other circumstances are capable of occasioning considerable differences in the results.

Fontana, Cavendish, Ladriani, Magellan, Von Humboldt, and Dr. Falconer, have made series of laborious experiments to bring the test of nitrous gas to a state of complete accuracy; but, notwithstanding the exertions of these philosophers, the methods of analyzing air by means of nitrous gas are liable to so many anomalies, that it is unnecessary to give a particular description of the different instruments invented by them.

2. *Scheele's Eudiometer.*

This is merely a graduated glass cylinder, containing a given quantity of air, exposed to a mixture of iron filings and sulphur, formed into a paste with water. The substances may be made use of in the following manner:

Make a quantity of sulphur in powder, and iron filings, into a paste with water, and place the mixture in a saucer, or plate, over water, on a stand raised above the fluid; then invert over it a graduated bell-glass, and allow this to stand for a few days. The air contained in the bell-glass will gradually diminish, as will appear from the ascent of the water.

When no further diminution takes place, the vessel containing the sulphuret must be removed, and the remaining air will be found to be nitrogen gas, which was contained in that quantity of atmospheric air.

In this process, the moistened sulphuret of iron has a great affinity to oxygen, it attracts and separates it from the atmospheric air, and the nitrogen gas is left behind; the sulphur, during the experiment, is converted into sulphuric acid, and the iron oxidized, and sulphate of iron results.

The air which is exposed to moistened iron and sulphur, gradually becomes diminished, on account of its oxygen combining with a portion of the sulphur and iron, while its nitrogen remains behind. The quantity of oxygen contained in the air examined becomes thus obvious, by the diminution of bulk, which the volume of air submitted to examination, has undergone.

A material error to which this method is liable, is that the sulphuric acid which is formed, acts partly on the iron, and produces hydrogen gas, which joins to some of the nitrogen forming ammonia; and hence it is that the absorption amounts in general to 0.27 parts, although the true quantity of oxygen is no more than from 0.21 to 0.22.

3. *De Marti's Eudiometer.*

De Marti obviated the errors to which the method of Scheele was liable. He availed himself, for that purpose, of a hydroguretted sulphuret, formed by boiling sulphur and liquid potash, or lime water, together. These substances, when newly prepared, have the property of absorbing a minute portion of nitrogen gas; but they lose this property when saturated with that gas, which is easily effected by agitating them for a few minutes in contact with a small portion of atmospheric air.

The apparatus is merely a glass tube, ten inches long, and rather less than half an inch in diameter, open at one end, and hermetically sealed at the other. The close end is divided into one hundred equal parts, having an interval of one line between each division. The use of this tube is to measure the portion of air to be employed in the experiment. The tube is filled with water; and by allowing the water to run out gradually, while the tube is inverted, and the open end kept shut with the finger, the graduated part is exactly filled with air. These hundred parts of air are introduced into a glass bottle, filled with liquid sulphuret of lime previously saturated with nitrogen gas, and capable of holding from two to four times the bulk of the air introduced. The bottle is then to be closed with a ground glass stopper, and agitated for five minutes. After this, the stopper is to be withdrawn, while the mouth of the phial is under water; and, for the greater accuracy, it may be closed and agitated again. Lastly, the air is to be again transferred to the graduated glass tube, in order to ascertain the diminution of its bulk.

4. *Humboldt's Eudiometer*

Consists in decomposing a definite quantity of atmospheric air, by means of the combustion of phosphorus, after which, the portion of gas which remains must be measured.

Take a glass cylinder, closed at the top, and whose capacity must be measured into sufficiently small portions by a graduated scale fixed on it. If the instrument be destined solely for examining atmospheric air, it will be sufficient to apply the scale from the orifice of the cylinder down to about half its length, or to sketch that scale on a slip of paper pasted on the outside of the tube, and to varnish it over with a transparent varnish.

This half of the eudiometrical tube is divided into fifty equidistant parts, which in this case indicate hundredth parts of the whole capacity of the instrument.

Into this vessel, full of atmospheric air, put a piece of dry phosphorus, (one grain to every twelve cubic inches,) close it air-tight, and heat it gradually, first the sides near the bottom, and afterwards the bottom itself. The phosphorus will take fire and burn rapidly. After every thing is cold, invert the mouth of the eudiometer-tube into a bason of water, and withdraw the cork. The water will ascend in proportion to the loss of oxygen gas the air has sustained, and thus its quantity may be ascertained.

Analogous to this is

5. *Seguin's Eudiometer,*

Which consists of a glass tube, of about one inch in diameter, and eight or ten inches high, closed at the upper extremity. It is filled with mercury, and kept inverted in this fluid in the mercurial trough. A small bit of phosphorus is introduced into it, which on account of its specific gravity being less than that of mercury, will rise up in it to the top. The phosphorus is then melted by means of a red-hot poker, or burning coal applied to the outside of the tube. When the phosphorus is liquified, small portions of air destined to be examined, and which have been previously measured in a vessel graduated to the cubic inch, or into grains, are introduced into the tube. As soon as the air which is sent up reaches the phosphorus, a combustion will take place, and the mercury will rise again. The combustion continues till the end of the operation; but, for the greater exactness, Mr. Seguin directs the residuum to be heated strongly. When cold, it is introduced into the graduated vessel to ascertain its volume. The difference of the two volumes gives the quantity of the oxygen gas contained in the air subjected to examination.

6. *Berthollet's Eudiometer.*

Instead of the rapid combustion of phosphorus, Berthollet has substituted its spontaneous combustion, which absorbs the oxygen of atmospheric air completely; and, when the quantity of air operated on is small, the process is accomplished in a short time.

Berthollet's apparatus consists of a narrow graduated glass tube, containing the air to be examined, into which is introduced a cylinder, or stick of phosphorus, supported upon a glass rod, while the tube stands inverted in water. The phosphorus should be nearly as long as the tube. Immediately after the introduction of the phosphorus, white vapours are formed which fill the tube; these vapours gradually descend, and become absorbed by the water. When no more white vapours appear, the process is at an end, for all the oxygen gas which was present in the confined quantity of air, has united with the phosphorus; the residuum is the quantity of nitrogen of the air submitted to examination.

This eudiometer, though excellent of the kind, is nevertheless not absolutely to be depended upon; for, as soon as the absorption of oxygen is completed, the nitrogen gas exercises an action upon the phosphorus, and thus its bulk becomes increased. It has been ascertained, that the volume of nitrogen gas is increased by 1-40th part; consequently the bulk of the residuum, diminished by 1-40, gives us the bulk of the nitrogen gas of the air examined; which bulk, subtracted from the original mass of air, gives us the proportion of oxygen gas contained in it. The same allowance must be made in the eudiometer of Seguin.

7. *Davy's Eudiometer.*

Until very lately, the preceding processes were the methods of determining the relative proportions of the two gases which compose our atmosphere.

Some of these methods, though very ingenious, are so extremely slow in their action, that it is difficult to ascertain the precise time at which the operation ceases. Others have frequently involved inaccuracies, not easily removed.

The eudiometer of Davy is not only free from these objections, but the result it offers is always constant; it requires little address, and is very expeditious; the apparatus is portable, simple, and convenient.

Take a small glass tube, graduated into one hundred equi-distant parts; fill this tube with the air to be examined, and plunge it into a bottle, or any other convenient vessel, containing a concentrated solution of green muriate or sulphate of iron, strongly impregnated with nitrous gas. All that is necessary to be done, is to move the tube in the solution a little backwards and forwards; under these circumstances, the oxygen gas contained in the air will be rapidly absorbed, and condensed by the nitrous gas in the solution, in the form of nitrous acid.

N. B. The state of the greatest absorption should be marked, as the mixture afterwards emits a little gas which would alter the result.

This circumstance depends upon the slow decomposition of the nitrous acid (formed during the experiment,) by the oxide of iron, and the consequent production of a small quantity of aëriform fluid (chiefly nitrous gas); which, having no affinity with the red muriate, or sulphate of iron, produced by the combination of oxygen, is gradually evolved and mingled with the residual nitrogen gas. However, the nitrous gas evolved might be abstracted by exposing the residuum to a fresh solution of green sulphate or muriate of iron.

The impregnated solution with green muriate, is more rapid in its operation than the solution with green sulphate. In cases when these salts cannot be obtained in a state of absolute purity, the common sulphate of iron of commerce may be employed. One cubic inch of moderately impregnated solution, is capable of absorbing five or six cubic inches of oxygen, in common processes; but the same quantity must never be employed for more than one experiment.

In all these different methods of analysing air, it is necessary to operate on air of a determinate density, and to take care that the residuum be neither more condensed nor dilated than the air was when first operated on. If these things are not attended to, no dependance whatever can be placed upon the result of the experiments, how carefully soever they may have been performed. It is, therefore, necessary to place the air, before and after the examination, into water of the same temperature. If this, and several other little circumstances have been attended to, for instance, a change in the height of the barometer, &c., we find that air is composed of about 0.21 of oxygen gas, and 0.79 of nitrogen gas by bulk. But as the weight of these two gases is not exactly the same, the proportion of the component parts by weight will differ a little; for as the specific gravity of oxygen is gas to that of nitrogen gas as 8 to 7 nearly, it follows that 100 parts of air are composed *by weight* of about 76 nitrogen gas, and 24 oxygen gas.

The air of this metropolis, examined by means of Davy's eudiometer, was found, in all the different seasons of the year to contain 0.21 of oxygen; and the same was the case with air taken at Islington and Highgate; in the solitary cells in Cold bath fields prison, and on the River Thames. But the quantity of water contained in a given bulk of air from these places, differed considerably.

EUGALENUS, **Severinus**, a physician of Doccum, in Friesland, known chiefly as the author of a treatise on the scurvy, in 1604, which once maintained a considerable character: but the publication of Dr. Lind, pointing out his numerous errors, has entirely superseded it.

EUGE′NIA. (So named by Micheli, in compliment to Prince Eugene of Savoy, who sent him from Germany almost all the plants described by Clusius.) The name of a genus of plants in the Linnæan system. Class, *Icosandria*. Order, *Monogynia*.

Euge′nia caryophylla′ta. The systematic name of the tree which affords the clove. *Caryophyllus aromaticus:* It grows in the East Indies, the Moluccas, &c. The clove is the unexpanded flower, or rather the calyx; it has a strong agreeable smell, and a bitterish, hot, not very pungent, taste. The oil of cloves, commonly met with in the shops, and received from the Dutch, is highly acrimonious, and sophisticated. Clove is accounted the hottest and most acrid of the aromatics; and, by acting as a powerful stimulant to the muscular fibres, may, in some cases of atonic gout, paralysis, &c. supersede most others of the aromatic class; and the foreign oil, by its great acrimony, is also well adapted for several external purposes: it is directed by several pharmacopœias, and the clove itself enters many officinal preparations.

Euge′nia ja′mbos. The systematic name of the Malabar plum-tree. The *Malabar plum*, which is the produce of the *Eugenia jambos*, smells, when ripe, like roses. On the coast of Malabar, where the trees grow plentifully, these plums are in great esteem. They are not only eaten fresh off the trees, but are preserved in sugar, in order to have them eatable all the year. Of the flowers, a conserve is prepared, which is used medicinally, as a mild adstringent.

Euge′us. (From ευ, well, and γη, the earth; so called because of its fertility.) The uterus.

Eu′lf. (From ευλαζω, to putrefy.) A worm bred in foul and putrid ulcers.

Eunu′chium. (From ευνουχος, an eunuch; so called because it was formerly said to render those who eat it impotent, like an eunuch.) The lettuce.

Eupatoriopha′lacron. (From ευπατωριον, agrimony, and φαλακρος, bald.) A species of agrimony with naked heads.

EUPATO′RIUM. (From *Eupator*, its discoverer: or *quasi hepatorium*, from ηπαρ, the liver; because it was said to be useful in diseases of the liver.)

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*. Order, *Polygamia æqualis*.

2. The pharmacopœial name of the *Eupatorium cannabinum;* which see.

Eupato′rium ara′bicum. See *Eupatorium cannabinum*.

Eupato′rium canna′binum. The systematic name of the hemp agrimony. *Eupatorium. Eupatorium Arabicum.* This very bitter and strong smelling plant, is the *Eupatorium foliis digitatis*, of Linnæus. Its juice proves violently emetic and purgative, if taken in sufficient quantity, and promotes the secretions generally. It is recommended in dropsies, jaundices, agues, &c. and is in common use in Holland, amongst the lower orders, as a purifier of the blood in old ulcers, scurvy, and anasarca.

Eupato′rium me′sues. See *Achillea ageratum*.

Eupe′psia. (From ευ, well, and πεπτω, to concoct. A good digestion.

Eupe′ptic. (*Eupeptica;* from ευ, good, and πεπτω, to digest.) Substances are so called that are easy to digest.

EUPHO′RBIA. The name of a genus of plants in the Linnæan system. Class, *Dodecandria*. Order, *Trigynia*.

Eupho′rbia antiquo′rum. The Linnæan name of a plant supposed to produce the *Euphorbium*.

Eupho′rbia canarie′nsis. In the Canary islands this species of spurge affords the gum euphorbium.

Eupho′rbia cypari′ssias. The systematic name of the cypress spurge. *Esula minor. Tithymalus cyparissius.* Cypress spurge. This, like most of the spurges, is very acrimonious, inflaming the eyes and œsophagus after touching them. It is now fallen into disuse, whatever were its virtues formerly, which, no doubt, amongst some others, was that of opening the bowels; for, amongst rustics, it was called poor man's rhubarb.

Eupho′rbia la′thyris. The systematic name of the plant which affords the lesser cataputia seeds. *Cataputia minor*, the *Euphorbia lathyris; umbella quadrifida, dichotoma, foliis oppositis integerrimis* of Linnæus. The seeds possess purgative properties; but if exhibited in an over-dose, prove drastic and poisonous: a quality peculiar to all the *euphorbiæ*.

Eupho′rbia officina′rum. The systematic name of the plant which affords the euphorbium in the greatest abundance. Euphorbium is an inodorus gum-resin, in yellow tears, which have the appearance of being worm-eaten; said to be obtained from several species of euphorbiæ, but principally from the *Euphorbia officinarum; aculatea nuda multangularis, aculeis germinatis*, of Linnæus: it is imported from Ethiopia, Libya, and Mauritania. It contains an active resin, and is very seldom employed internally, but, as an ingredient, it enters into many resolvent and discutient plasters.

Eupho′rbia palu′stris. The systematic name of the greater spurge. *Esula major.* The officinal plant ordered by this name in some pharmacopœias, is the *Euphorbia palustris: umbella multifida, bifida, involucellis ovatis, foliis lanceolatis, ramis sterilibus*, of Linnæus. The juice is exhibited in Russia as a common purge; and the plant is given, in some places, in the cure of intermittents.

Eupho′rbia para′lias. *Tithymalus paralios.* Sea spurge. Every part of this plant, *Euphorbia paralias* of Linnæus, is violently cathartic and irritating, inflaming the mouth and fauces. It is seldom employed in the practice of this country; but where it is used vinegar is recommended to correct its irritating power.

EUPHO′RBIUM. (From *Euphorbus*, the physician of king Juba, in honour of whom it was named.) See *Euphorbia officinarum.*

EUPHRA′SIA. (Corrupted from *Euphrosyne*, *ευφροσυνη*, from *ευφρων*, joyful; so called because it exhilarates the spirits.)

1. The name of a genus of plants in the Linnæan system. Class, *Didynamia.* Order, *Angiospermia.*

2. The pharmacopœial name of eye-bright. See *Euphrasia officinalis.*

Euphra′sia officina′lis. The systematic name of the eye-bright. This beautiful little plant, *Euphrasia officinali; foliis ovatis, lineatis, argute dentatis*, of Linnæus, has been greatly esteemed by the common people, as a remedy for all diseases of the eyes; yet, notwithstanding this, and the encomiums of some medical writers, is now wholly fallen into disuse. It is an ingredient in the British herb-tobacco.

EUSTA′CHIAN TUBE. *Tuba Eustachiana.* The tube so called was discovered by the great Eustachius. It begins, one in each ear, from the anterior extremity of the tympanum, and runs forwards and inwards in a bony canal, which terminates with the petrous portion of the temporal bone. It then goes on, partly cartilaginous, and partly membranous, gradually becoming larger, and at length ends behind the soft palate. Through this tube the air passes to the tympanum.

Eustáchian valve. See *Valvula Eustachii.*

EUSTACHIUS, Bartholomew, one of the most celebrated anatomists of the 16th century, was born at San Severino in Italy. He studied at Rome, and made himself such a proficient in anatomy, that he was chosen professor of that branch of medicine there, where he died in 1574. He was author of several works, many of which are lost, especially his treatise "De Controversiis Anatomicorum," which is much regretted. He made several discoveries in anatomy; having first described the renal capsules, and the thoracic duct; also the passage from the throat to the internal ear, named after him the Eustachian tube. A series of copper plates, to which he alludes in his "Opuscula," were recovered by Lancisi, and published in the beginning of the 18th century. He edited the Lexicon of Erotian with a commentary.

Euthypo′ria. (From *ευθυς*, straight, and *πορος*, a passage.) *Euthyporos.* An extension made in a straight line, to put in place a fracture, or dislocation.

EVAPORA′TION. The volatilization of a fluid, by means of heat, with access of air, in order to diminish its fluidity, to obtain any fixed salts it may hold in solution, or to diminish the quantity of a residuum. In this manner sea water is evaporated, and the salt obtained, and decoctions made into extracts.

Everri′culum. (From *everro*, to sweep away.) A sort of spoon, used to clear the bladder from gravel.

EXACERBA′TION. (From *exacerbo*, to become violent.) An increase of febrile symptoms.

Exæ′resis. (From *εξαιρεω*, to remove.) One of the divisions of surgery, adopted by the old surgeons; the term implies the removal of parts.

Exa′lma. (From *εξαλλομαι*, to leap out.) Hippocrates applies it to the starting of the vertebræ out of their places.

Examelo′ma. (From εξαμβλοω, to miscarry.) An abortion.

Examblo′sis. An abortion.

Exanastomo′sis. (From εξαναστομοω, to relax, or open.) The opening of the mouths of vessels, to discharge their contents; also the meeting of the extremities of the veins and arteries.

EXANTHE′MA. (From εξανθεω, to spring forth, to bud.) *Exanthisma.* An eruption of the skin.

EXANTHE′MATA. (The plural of *exanthema.*) The name of an order of diseases of the class *pyrexiæ* in Cullen's Nosology. It includes diseases, beginning with fever, and followed by an eruption on the skin.

Exanthi′sma. See *Exanthema.*

Exanthro′pia. (From εξ, without, and ανθρωπος, a man, *i. e.* having lost the faculties of a man.) A species of melancholy, where the patient fancies himself some kind of brute.

Exara′gma. (From εξαραττω, to break.) A fracture.

Exa′rma. (From εξαιρω, to lift up.) A tumour; a swelling.

Exarte′ma. (From εξαρταω, to suspend.) An amulet, or charm, hung round the neck.

Exarthre′ma. (From εξαρθροω, to put out of joint.) *Exarthroma. Exarthrosis.* A dislocation, or luxation.

Exarthro′ma. See *Exarthrema.*

Exarthro′sis. See *Exarthrema.*

Exarticula′tio. (From *ex,* out of, and *articulus,* a joint.) A luxation, the dislocation of a bone from its socket.

Exci′pulum. (From *excipio,* to receive.) A chemical receiver.

EXCITABI′LITY. See *Excitement.*

EXCI′TEMENT. A term introduced into medicine by Dr. Brown. Animals, differ from themselves in their dead state, or from any other inanimate matter, in this property alone; *they can be affected by external agents, as well as by certain functions peculiar to themselves in such a manner, that the phenomena peculiar to the living state can be produced.* This proposition extends to every thing that is vital in nature, and therefore applies to vegetables.

The external agents are reducible to heat, diet, and other substances taken into the stomach, blood, the fluids secreted from the body and air.

The functions of the system itself, producing the same effect, are muscular contraction, sense, or perception, and the energy of the brain in thinking, and in exciting passion and emotion. These affect the system in the same manner as the other agents; and they arise both from the other and from themselves.

If the property which distinguishes living from dead matter, or the operation of either of the two sets of powers be withdrawn, life ceases. Nothing else than the presence of these is necessary to life.

The property on which both sets of powers act Dr. Brown names *Excitability,* and the powers themselves exciting powers. The word body, means both the body simply so called, and also as endued with an intellectual part, a part appropriated to passion and emotion, or a soul: the usual appellation in medical writings is system.

The effects common to all the exciting powers, are sense, motion, mental exertion, and passion. Their effects being the same, it must be granted, that the operation of all their powers is the same.

The effects of the exciting powers acting upon the excitability, Dr. Brown denominates *excitement.*

EXCI′TING CAUSE. Occasional cause. Procatarctic cause. Remote cause. That which, when applied to the body, excites a disease. The exciting, or remote causes of diseases, are either external or internal.

EXCORIA′TION. (From *excorio,* to take off the skin.) *Excoriatio.* An abrasion of the skin.

E′XCREMENT. (From *excerno,* to separate from.) The alvine fæces.

EXCRE′SCENCE. (From *excresco,* to grow from.) *Excrescentia.* Any preternatural formation of flesh, or any part of the body, as wens, warts, &c.

EXCRE′TION. (From *excerno,* to separate from.) *Excretio.* This term is applied to the separation or secretion of those fluids from the blood of an animal, that are supposed to be useless, as the urine, perspiration, and alvine fæces.

EXFOLIA′TION. (From *exfolio,* to cast the leaf.) *Exfoliatio.* The separation of a dead piece of bone from the living.

Exfoliati′vum. (From *exfolio,* to shed the leaf.) A raspatory or instrument for scraping exfoliating portions of bone.

Exi′schios. (From εξ, out of, and ισχιον, the ischium.) A luxation of the thigh-bone.

Exitu′ra. (From *exeo,* to come from.) A running abscess.

E′xitus. (From *exeo,* to come out.) A prolapsus, or falling down of the womb or anus.

E′xochas. (From εξω, without, and εχω, to have.) *Exoche.* A tubercle on the outside of the anus.

E′xoche. See *Exochas.*

Exocy′ste. See *Exocystis.*

Exocy′stis. (From εξω, without, and κυσις, the bladder.) *Exocyste.* A prolapsus of the inner membrane of the bladder.

EXO′MPHALUS. (From εξ, out, and ομφαλος, the navel.) *Exomphalos.* An umbilical hernia. See *Hernia.*

Exoncho′ma. (From εξ, and ογκος, a tumour.) A large prominent tumour.

EXOPHTHA'LMIA. (From εξ, out, and οφθαλμος, the eye.) A swelling or protrusion of the bulb of the eye, to such a degree that the eye-lids cannot cover it. It may be caused by inflammation, when it is termed *exophthalmia inflammatoria*; or from a collection of pus in the globe of the eye, when it is termed the *exophthalmia purulenta*; or from a congestion of blood within the globe of the eye, *exophthalmia sanguinea*.

EXOSTO'SIS. (From εξ, and οστεον, a bone.) *Hyperostosis*. A morbid enlargement, or hard tumour of a bone. A genus of disease arranged by Cullen in the class *locales*, and order *tumores*. The bones most frequently affected with extososis, are those of the cranium, the lower jaw, sternum, humerus, radius, ulna, bones of the carpus, the femur, and tibia. There, is however, no bone of the body, which may not become the seat of this disease. It is not uncommon to find the bones of the cranium affected with exostosis, in their whole extent. The ossa parietalia sometimes become an inch thick.

The exostosis, however, mostly rises from the surface of the bone, in the form of a hard round tumour; and venereal exostoses, or nodes, are observed to arise chiefly on compact bones, and such of these as are only superficially covered with soft parts; as, for instance, the bones of the cranium, and the front surface of the tibia.

EXPE'CTORANTS. (*Expectorantia*, sc. *medicamenta*, from *expectoro*, to discharge from the breast.) Those medicines which increase the discharge of mucus from the lungs. The different articles referred to this class may be divided into the following orders: 1. *Nauseating expectorants*, as squill, ammoniacum, and garlic, which are to be preferred for the aged and phlegmatic. 2. *Stimulating expectorants*, as marrubium, which is adapted to the young and irritable, and those easily affected by expectorants. 3. *Antispasmodic expectorants*, as vesicatories, pediluvium, and watery vapours; these are best calculated for the plethoric and irritable, and those liable to spasmodic affections. 4. *Irritating expectorants*, as fumes of tobacco and acid vapours. The constitutions to which these are chiefly adapted, are those past the period of youth, and those in whom there are evident marks of torpor, either in the system generally, or in the lungs, in particular.

EXPIRA'TION. (From *expiro*, to breathe.) *Expiratio*. That part of respiration in which the air is thrust out from the lungs. See *Respiration*.

Expre'ssed oils. Such oils as are obtained by pressing the substance containing them, as olives, which give out olive oil, almonds, &c.

Exsucca'tio. (From *ex*, out of, and *succus*, humour.) An ecchymosis, or extravasation of humours, under the integuments.

EXTE'NSOR. (From *extendo*, to stretch out.) A term given to those muscles whose office it is to extend any part; the term is in opposition to flexor.

EXTE'NSOR BRE'VIS DIGITO'RUM PE'DIS. *Extensor brevis* of Douglas. *Calcano phalanginien commune* of Dumas. A muscle of the toes situated on the foot. It arises fleshy and tendinous from the fore and upper part of the os calcis, and soon forms a fleshy belly, divisible into four portions, which send off an equal number of tendons that pass over the upper part of the foot, under the tendons of the extensor longus digitorum pedis, to be inserted into its tendinous expansion. Its office is to extend the toes.

EXTE'NSOR CA'RPI RADIA'LIS BRE'VIOR. *Radialis externus brevior* of Albinus. *Radialis secundus* of Winslow. An extensor muscle of the wrist, situated on the fore-arm. It arises tendinous from the external condyle of the humerus, and from the ligament that connects the radius to it, and runs along the outside of the radius. It is inserted by a long tendon into the upper and back part of the metacarpal bone of the middle finger. It assists in extending and bringing the hand backward.

EXTE'NSOR CA'RPI RADIA'LIS LO'NGIOR. *Radialis externus longior* of Albinus. *Radialis externus primus* of Winslow. An extensor muscle of the carpus, situated on the fore-arm, that acts in conjunction with the former. It arises thin, broad, and fleshy, from the lower part of the external ridge of the os humeri, above its external condyle, and is inserted by a round tendon into the posterior and upper part of the metacarpal bone that sustains the fore-fingers.

EXTE'NSOR CA'RPI ULNA'RIS. *Ulnaris externus* of Albinus and Winslow. It arises from the outer condyle of the os humeri, and then receives an origin from the edge of the ulna: its tendon passes in a groove behind the styloid process of the ulna to be inserted into the inside of the basis of the metacarpal bone of the little finger.

EXTE'NSOR DIGITO'RUM COMMU'NIS. *Cum extensore proprio auricularis* of Albinus. *Extensor digitorum communis manus* of Douglas and Winslow. *Extensor digitorum communis, seu digitorum tensor* of Cowper, and *Epichondylo-susphalangettien commune* of Dumas. A muscle situated on the fore-arm, that extends all the joints of the fingers. It arises from the external protuberance of the humerus: and at the wrist it divides into three flat tendons, which pass under the annular ligament, to be inserted into all the bones of the fore, middle, and ring fingers.

EXTE'NSOR DIGITO'RUM LO'NGUS. See *Extensor longus digitorum pedis.*

EXTE'NSOR I'NDICIS. See *Indicator.*

EXTE'NSOR LO'NGUS DIGITO'RUM PE'DIS. *Extensor digitorum longus. Peroneo tibisus phalangittien commune* of Dumas. A muscle situated on the leg, that extends all the joints of the four small toes. It arises from the upper part of the tibia and fibula, and the interrosseous ligament; its tendon passes under the annular ligament, and then divides into five, four of which are inserted into the second and third phalanges of the toes, and the fifth goes to the basis of the metatarsal bone. This last, Winslow reckons a distinct muscle, and calls it *Peroneus brevis.*

EXTE'NSOR LO'NGUS PO'LLICIS PE'DIS. See *Extensor proprius pollicis pedis.*

EXTE'NSOR MA'GNUS. See *Gastrocnemius internus.*

EXTE'NSOR MA'JOR PO'LLICIS MA'NUS. See *Extensor secundi internodii.*

EXTE'NSOR MI'NOR PO'LLICIS MA'NUS. See *Extensor primi internodii.*

EXTE'NSOR O'SSIS METACA'RPI PO'LLICIS MA'NUS. *Abductor longus pollicis manus* of Albinus. *Extensor primi internodii* of Douglas. *Extensor primus pollicis* of Winslow. *Extensor primi internodii pollicis* of Cowper. *Cubito-radisus metacarpien du pouce* of Dumas. It arises fleshly from the middle and posterior part of the ulna, from the posterior part of the middle of the radius, and from the interosseous ligament, and is inserted into the os trapezium, and upper part of the metacarpal bone of the thumb.

EXTE'NSOR PO'LLICIS PRI'MUS. See *Extensor primi internodii.*

EXTE'NSOR PO'LLICIS SECU'NDUS. See *Extensor secundi internodii.*

EXTE'NSOR PRI'MI INTERNO'DII. *Extensor minor pollicis manus* of Albinus. This muscle, and the *Extensor ossis metacarpi pollicis manus,* are called *Extensor pollicis primus* by Winslow. *Extensor secundi internodii* by Douglas. *Extensor secundi internodii ossis pollicis* of Cowper. *Cubito-susphalangien du pouce* of Dumas. A muscle of the thumb situated on the hand, that extends the first bone of the thumb obliquely outwards. It arises fleshy from the posterior part of the ulna, and from the interrosseous ligament, and is inserted tendinous into the posterior part of the first bone of the thumb.

EXTE'NSOR PRO'PRIUS PO'LLICIS PE'DIS. *Extensor longus* of Douglas. *Extensor pollicis longus* of Winslow and Cowper. *Peroneo susphalangien du pouce* of Dumas. An exterior muscle of the great toe, situated on the foot. It arises by an acute, tendinous, and fleshy beginning, some way below the head, and anterior part of the fibula, along which it runs to near its lower extremity, connected to it by a number of fleshy fibres, which descend obliquely, and form a tendon, which is inserted into the posterior part of the first and last joint of the great toe.

EXTE'NSOR SECU'NDI INTERNO'DII. *Extensor major pollicis manus* of Albinus. *Extensor pollicis secundus* of Winslow. *Extensor tertii internodii* of Douglas. *Extensor internodii ossis pollicis* of Cowper. *Cubito susphalangettien du pouce* of Dumas. A muscle of the thumb, situated on the hand, that extends the last joint of the thumb obliquely backwards. It arises tendinous and fleshy from the middle part of the ulna, and interosseous ligament; it then forms a tendon, which runs through a small groove at the inner and back part of the radius, to be inserted into the last bone of the thumb. Its use is to extend the last phalanx of the thumb obliquely backwards.

EXTE'NSOR SECU'NDI INTERNO'DII I'NDICIS PRO'PRIUS. See *Indicator.*

EXTE'NSOR TA'RSI MI'NOR. See *Plantaris.*

EXTE'NSOR TA'RSI SURA'LIS. See *Gastrocnemius internus.*

EXTE'NSOR TE'RTII INTERNO'DII MI'NIMI DI'GITI. See *Abductor minimi digiti manus.*

EXTE'NSOR TE'RTII INTERNO'DII I'NDICIS. See *Prior indicis.*

EXTE'RNUS MA'LLEI. See *Laxator tympani.*

EXTIRPA'TION. (From *extirpo,* to eradicate.) *Extirpatio.* The complete removal or destruction of any part, either by cutting instruments, or the action of caustics.

EXTRA'CTION. (From *extraho,* to draw out.) *Extractio.* The taking extraneous substances out of the body. Thus bullets and splinters are said to be *extracted* from wounds; stones from the urethra, or bladder.

Surgeons also sometimes apply the term *extraction* to the removal of tumours out of cavities, as, for instance, to the taking of cartilaginous tumours out of the joints. They seldom speak of extracting any diseased original part of the body; though they do so in one example, viz. the cataract.

E'XTRACT. (*Extractum;* from *extraho,* to draw out.) The generic term extract is used pharmaceutically, in an extensive sense, and includes all those preparations from vegetables which are separated by the agency of various liquids, and afterwards obtained from such solutions, in a solid state, by evaporation of the menstruum. It also includes those substances which are held in solution by the natural juices of fresh plants, as well as those to which some menstruum is added at the time of preparation. Now, such soluble matters are various, and mostly complicated; so that chemical accuracy is not to be looked for in the application of the term. Some chemists, however, have affixed this name to one peculiar modification of vegetable matter, which has been called *extractive*, or extract, or extractive principle; and, as this forms one constituent part of common extracts, and possesses certain characters, it will be proper to mention such of them as may influence its pharmaceutical relations. The extractive principle has a strong taste, differing in different plants: it is soluble in water, and its solution speedily runs into a state of putrefaction, by which it is destroyed. Repeated evaporations and solutions render it at last insoluble, in consequence of its combination with oxygen from the atmosphere. It is soluble in alkohol, but insoluble in ether. It unites with alumine, and if boiled with neutral salts thereof, precipitates them. It precipitates with strong acids, and with the oxides from solutions of most metallic salts, especially muriate of tin. It readily unites with alkalies, and forms compounds with them, which are soluble in water. No part, however, of this subject has been hitherto sufficiently examined.

In the preparation of all the extracts, the London Pharmacopœia requires that the water be evaporated as speedily as possible, in a broad, shallow dish, by means of a water-bath, until they have acquired a consistence proper for making pills; and, towards the end of the inspissation, that they should be constantly stirred with a wooden rod. These general rules require minute and accurate attention, more particularly in the immediate evaporation of the solution, whether prepared by expression or decoction, in the manner as well as the degree of heat by which it is performed, and the promotion of it by changing the surface by constant stirring, when the liquor begins to thicken, and even by directing a strong current of air over its surface, if it can conveniently be done. It is impossible to regulate the temperature over a naked fire, or, if it be used, to prevent the extract from burning; the use of a water bath is, therefore, absolutely necessary, and not to be dispensed with, and the beauty and precision of extracts so prepared, will demonstrate their superiority.

EXTRA'CTIVE. See *Extract*.

Extra'ctum aconi'ti. Extract of aconite. "Take of aconite leaves, fresh a pound; bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without any separation of the sediment, evaporate it to a proper consistence." The dose is from one grain to five grains. For its virtues see *Aconitum*.

Extra'ctum a'loes purifica'tum. Purified extract of aloes. "Take of extract of spike aloe, powdered, half a pound; boiling water, four pints. Macerate for three days in a gentle heat, then strain the solution, and set it by, that the dregs may subside. Pour off the clear solution, and evaporate it to a proper consistence." The dose, from five to xv grs. See *Aloës.*

Extra'ctum anthe'midis. Extract of chamomile, formerly called extractum chamæmeli. "Take of chamomile flowers, dried, a pound. Water, a gallon. Boil down to four pints, and strain the solution while it is hot, then evaporate it to a proper consistence." The dose is x grs. to a scruple. For its virtues, see *Anthemis nobilis.*

Extra'ctum bellado'nnæ. Extract of belladonna. "Take of deadly night shade leaves, fresh, a pound. Bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and without any previous separation of the sediment, evaporate it to a proper consistence." The dose is from one to five grains. For its virtues, see *Atropa Belladonna*.

Extra'ctum cincho'næ. Extract of bark. "Take of lance-leaved cinchona bark, bruised, a pound; water a gallon. Boil down to six pints, and strain the liquor, while hot. In the same manner, with an equal quantity of water, four times boil down, and strain. Lastly consume all the liquors, mixed together, to a proper consistence. This extract should be kept soft, for making pills, and hard to be reduced to powder."

Extra'ctum cincho'næ resino'sum. Resinous extract of bark. "Take of lance-leaved cinchona bark, bruised, a pound; rectified spirit, four pints. Macerate for four days and strain. Distil the tincture in the heat of a water-bath, until the extract has acquired a proper consistence." This is considered by many as much more grateful to the stomach, and, at the same time, producing all the effects of bark in substance, and by the distillation of it, it is intended that the spirit which passes over shall be collected and preserved. The dose is from ten grains to half a drachm. See *Cinchona*.

Extra'ctum colocy'nthidis. Extract of colocynth. "Take of colocynth pulp, a pound; water, a gallon. Boil down to four pints, and strain the solution while it is hot, and evaporate it to a proper consistence." The dose is from five to thirty grains. For its virtues, see *Cucumis colocynthis*.

Extra'ctum coloc'ynthidis compo'situm. Compound extract of colocynth. "Take of colocynth pulp, sliced, six drachms; extract of spike aloe, powdered, an ounce and half; scammony gum-resin powdered, half an ounce; cardamom seeds powdered, a drachm; proof spirit; a pint. Macerate the colocynth pulp in the spirit, for four days, in a gentle heat: strain the solution, and add it to the aloes and scammony; then, by means of a water-bath, evaporate it to a proper consistence, constantly stirring and about the end of the inspissation, mix in the cardamom-seeds." The dose from five to thirty grains.

Extra′ctum coni′i. Extract of hemlock, formerly called succus cicutæ spissatus. "Take of fresh hemlock, a pound. Bruise it in a stone mortar, sprinkling on a little water; then press out the juice, and, without any separation of the sediment, evaporate it to a proper consistence." The dose from five grains to a scruple.

Extra′ctum elate′rii. Extract of elaterium. "Cut the ripe, wild cucumbers into slices, and pass the juice, very gently expressed, through a very fine hair sieve, into a glass vessel; then set it by for some hours, until the thicker part has subsided. Pour off, and throw away the thinner part, which swims at the top. Dry the thicker part which remains in a gentle heat." The dose, from half a grain to three grains. For its virtues, see *Momordica Elaterium.*

Extra′ctum gentia′næ. Extract of gentian. "Take of gentian root, sliced, a pound; boiling water, a gallon. Macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence." Dose from ten to thirty grains. See *Gentiana.*

Extra′ctum glycyrrhi′zæ. Extract of liquorice. "Take of liquorice root, sliced, a pound; boiling water, a gallon. Macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence." Dose, from one drachm to half an ounce. See *Glycyrrhiza.*

Extra′ctum hæmato′xyli. Extract of logwood, formerly called extractum ligni campechensis. "Take of logwood, powdered, a pound; boiling water, a gallon. Macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence." Dose from ten grains to half a drachm. For its virtues, see *Hæmatoxylon campechianum.*

Extra′ctum hu′muli. Extract of hops, "Take of hops, four ounces; boiling water, a gallon. Boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence." This extract is said to produce a tonic and sedative power combined. The dose is from five grains to one scruple. See *Humulus Lupulus.*

Extra′ctum hyoscy′ami. Extract of henbane. "Take of fresh henbane leaves, a pound. Bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without separating the fæculencies, evaporate it to a proper consistence." Dose from five to thirty grains. For its virtues, see *Hyoscyamus.*

Extra′ctum jala′pæ. Extract of jalap. "Take of jalap-root powdered, a pound; rectified spirit, four pints; water, ten pints. Macerate the jalap root in the spirit for four days, and pour off the tincture; boil the remaining powder in the water, until it be reduced to two pints; then strain the tincture and decoction separately, and let the former be distilled and the latter evaporated, until each begins to grow thick. Lastly, mix the extract with the resin, and reduce it to a proper consistence. Let this extract be kept in a soft state, fit for forming pills, and in a hard one, so that it may be reduced to powder." The dose, from ten to twenty grains. For its virtues, see *Convolvulus jalapa.*

Extra′ctum o′pii. Extract of opium, formerly called extractum thebaicum. Opium colatum. "Take of opium, sliced, half a pound; water, three pints. Pour a small quantity of the water upon the opium, and macerate it for twelve hours, that it may become soft; then, adding the remaining water gradually, rub them together until the mixture be complete. Set it by, that the fæculencies may subside; then strain the liquor, and evaporate it to a proper consistence." Dose, from half a grain to five grains.

Extra′ctum papa′veris. Extract of white poppy. "Take of white poppy capsules bruised, and freed from the seeds, a pound; boiling water, a gallon. Macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence." Six grains are about equivalent to one of opium. For its virtues, see *Papaver album.*

Extra′ctum rhe′i. Extract of rhubarb. "Take of rhubarb root, powdered, a pound; proof spirit, a pint; water, seven pints. Macerate for four days in a gentle heat, then strain and set it by, that the fæculencies may subside. Pour off the clear liquor, and evaporate to a proper consistence." This extract possesses the purgative properties of the root, and the fibrous and earthy parts are separated; it is, therefore, a useful basis for pills, as well as given separately. Dose, from ten to thirty grains. See *Rheum.*

Extra′ctum sarsapari′llæ. Extract of sarsaparilla. "Take of sarsaparilla root, sliced, a pound; boiling water, a gallon. Macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence." In practice this is much used, to render the common decoction of the same root stronger and more efficacious. Dose from ten grains to a drachm. For its virtues, see *Smilax sarsaparilla.*

Extra′ctum satu′rni. See *Plumbi subacetatis liquor.*

Extra′ctum tara′xaci. "Take of dandelion root, fresh and bruised, a pound; boiling water, a gallon. Macerate for twenty-four hours; boil down to four pints, and strain the hot liquor; then evaporate it to a proper consistence." Dose, from ten grains to a drachm. For its virtues, see *Leontodon Taraxacum.*

EXTRAVASATION. (From *extra*, without, and *vas*, a vessel.) *Extravasatio.* A term applied by surgeons to fluids, which are out of their proper vessels, or receptacles. Thus, when blood is effused on the surface, or in the ventricles of the brain, it is said that there is an extravasation. When blood is poured from the vessels into the cavity of the peritoneum, in wounds of the abdomen, surgeons call this accident *extravasation.* The urine is also said to be *extravasated*, when, in consequence of a wound, or of sloughing, or ulceration, it makes its way into the cellular substance or among the abdominal viscera. When the bile spreads among the convolutions of the bowels, in wounds of the gall-bladder it is also a species of extravasation.

EYE. *Oculus.* The parts which constitute the eye are divide into external and internal. The external parts are:

1. The *eyebrows*, or *supercilia*, which form arches of hair above the orbit, at the lower part of the forehead. Their use is to prevent the sweat falling into the eyes, and for moderating the light above.

2. The eyelashes, or *cilia*, are the short hairs that grow on the margin of the eyelids; they keep external bodies out of the eyes, and moderate the influx of light.

3. The eyelids, or *palpebræ*, of which, one is superior or upper, and the other inferior, or under; where they join outwardly, it is called the *external canthus*; inwardly, towards the nose, the *internal canthus*; they cover and defend the eyes.

The margin of the eyelids, which is cartilaginous, is called *tarsus.*

In the *tarsus*, and internal surface of the eyelids, small glands are situated, called *glandulæ Meibomianæ*, because Meibomius discovered them; they secrete an oily or mucilaginous fluid, which prevents the attrition of the eyes and eyelids, and facilitates their motions.

4. The lachrymal glands, or *glandulæ lachrymales*, which are placed near the external canthus, or corner of the eyes, in a little fovea of the os frontis.

From these glands six or more canals issue, which are called lachrymal ducts, or *ductus lachrymales*, and they open on the internal surface of the upper eyelid.

5. The lachrymal caruncle, or *caruncula lachrymalis*, which is situated in the internal angle, or canthus of the eyelids.

6. *Puncta lacrymalia*, are two callous orifices or openings, which appear at the internal angle of the tarsus of the eyelids; the one in the superior, the other in the inferior eyelid.

7. The lachrymal ducts or *canales lachrymales*, are two small canals, which proceed from the lachrymal points into the lachrymal sac.

8. The lachrymal sac, or *saccus lachrymalis*, is a membranous sac, which is situated in the internal canthus of the eye.

9. The nasal duct, or *ductus nasalis*, is a membranous canal, which goes from the inferior part of the lachrymal sac through the bony canal below, and a little behind, into the cavity of the nose, and opens under the inferior spongy bone into the nostrils.

10. The conjunctive membrane, or *membrana conjunctiva*, which, from its white colour, is called also *albuginea*, or white of the eye, is a membrane which lines the internal superficies of the eyelids, and covers the whole fore-part of the globe of the eye; it is very vascular, as may be seen in inflammations.

The bulb, or globe of the eye, is composed of eight membranes, or coverings, two chambers, or *cameræ*, and three humours, improperly so called.

The membranes of the globe of the eye, are, *four* in the hinder or posterior part of the bulb, or globe, viz. *sclerotica*, *choroidea*, *retina*, and *hyaloidea*, or *arachnoidea*; *four* in the fore or anterior part of the bulb, viz. *cornea transparens*, *iris*, *uvea*, and *capsule of the crystalline lens.*

The *membrana sclerotica*, or the sclerotic or horny membrane, which is the outermost, begins from the optic nerve, forms the spherical or globular cavity, and terminates in the circular margin of the transparent cornea.

The *membrana choroidea*, or *choroides*, is the middle tunic of the bulb, of a black colour, beginning from the optic nerve, and covering the internal superficies of the sclerotica, to the margin of the transparent cornea. In this place it secedes from the cornea, and deflects transversely and inwardly, and in the middle forms a round foramen. This circular continuation of the choroidea in the anterior surface is called *iris*, in the posterior superficies, *uvea.*

The round opening in the centre is called the *pupil*, or *pupilla*. This foramen, or round opening, can be dilated, or contracted, by the moving powers of almost invisible muscular fibres.

The *membrana retina*, is the innermost tunic of a white colour, and similar to mucus, being an expansion of the optic nerve, chiefly composed of its medullary part. It covers the inward superficies of the choroides, to the margin of the crystalline lens, and there terminates.

The *chambers*, or *cameræ* of the eyes are:

1. *Camera anterior*, or fore-chamber; an open space, which is formed anteriorly, by the hollow surface of the *cornea transparens*, and posteriorly, by the surface of the *iris.*

2. *Camera posterior,* that small space which is bounded anteriorly by the *tunica uvea,* and *pupilla,* or pupil; posteriorly by the anterior surface of the crystalline lens.

Both these chambers are filled with aqueous humour. The humours of the eye, as they are called, are in number three:

1. The *aqueous humour,* which fills both chambers.

2. The *crystalline lens,* or humour, is a pellucid body, about the size of a lentil, which is included in an exceedingly fine membrane, or *capsula,* and lodged in a concave fovea of the vitreous humour.

3. The *vitreous humour,* is a pellucid, beautifully transparent substance, which fills the whole bulb of the eye behind the crystalline lens. Its external surface is surrounded with a most pellucid membrane, which is called *membrana hyaloidea,* or *arachnoidea.* In the anterior part is a fovea, or bed, for the crystalline lens.

The connection of the bulb is made anteriorly, by means of the conjunctive membrane, with the inner surface of the eyelids, or *palpebræ;* posteriorly, by the adhesion of six muscles of the bulb and the optic nerve, with the orbit.

The optic nerve, or *nervus opticus,* perforates the sclerotica and choroides, and then constitutes the retina, by spreading itself on the whole posterior part of the internal globe of the eye.

The muscles by which the eye is moved in the orbit, are six; much adeps surrounds them, and fills up the cavities in which the eyes are seated. The arteries are the internal orbital, the central, and the ciliary arteries. The veins empty themselves into the external jugulars. The nerves are the optic, and branches from the third, fourth, fifth, and sixth pair.

The use of the eye is to form the organ of vision.

Externally, the globe of the eye and the transparent cornea, are moistened with a most limpid fluid, called *lachrymæ,* or tears; the same pellucid subtile fluid exactly fills all the pores of the transparent cornea; for, deprived of this fluid, and being exposed to the air, that coat of the eye becomes dry, shrivelled, and cloudy, impeding the rays of light.

Eye-bright. See *Euphrasia.*

EYE-BROW. *Supercilium.* A layer of short hair, which lies thick upon the integuments covering the superior prominent part of the orbit.

EYE-LID. *Palpebra.* The semi-lunar moveable production of the skin which covers the eye when shut. It is distinguished into upper and under eye-lid.

F.

F. or ft. In a prescription these letters are abbreviations of *fiat,* or *fiant,* let it, or them be made; thus *f. bolus,* let the substance or substances prescribed be made into a bolus.

FA´BA. See *Bean.*

FA´BA CRA´SSA. See *Sedum telephium.*

FA´BA ÆGYPTI´ACA. See *Nymphæa Nelumbo.*

FA´BA FEBRI´FUGA. See *Ignatia amara.*

FA´BA I´NDICA. See *Ignatia amara.*

FA´BA MA´JOR. The Turkey or garden bean. See *Bean.*

FA´BA MI´NOR. *Equina frasa.* The horse-bean. It differs no otherwise from the garden bean than in being less.

FA´BA PECHU´RIM. *Faba pichurim. Faba pechuris.* An oblong oval, brown, and ponderous seed, supposed to be the produce of a *Laurus,* brought from the Brazils. Their smell is like that of musk, between it and the scent of sassafras. They are exhibited as carminatives in flatulent colics, diarrhœas, and dysenteries.

FA´BA PURGA´TRIX. See *Ricinus.*

FA´BA SA´NCTI IGNA´TII. See *Ignatia amara.*

FA´BA SUI´LLA. See *Hyoscyamus.*

FABA´RIA. (From *faba,* a bean, which it resembles.) Orphine. See *Sedum telephium.*

FABRICIUS, HIERONYMUS, born at *Aquapendente* in Italy, 1537. He studied at Padua under Fallopius, whom he succeeded as professor of anatomy and surgery there; which office he held for nearly half a century with great credit, and died at the advanced age of eighty-two universally regretted. The republic of Venice also conferred many honours upon him. He is thought to have been the first to notice the valves of the veins, which he demonstrated in 1574. But his surgical works obtained him most reputation; indeed he has been called the Father of modern surgery. His first publication in 1592 contained five Dissertations on Tumours, Wounds, Ulcers, Fractures, and Dislocations. He afterwards added another part, treating of all the Diseases, which are curable by manual Operation. This work passed through seventeen editions in different languages.

FABRICIUS, James, was born at Rostock in 1577. After travelling through different parts of Europe, he graduated at Jena, and soon gained extensive practice. He was professor of medicine and the mathematics at Rostock during forty years, and first physician to the Duke of Mecklenburgh; afterwards went to Copenhagen, and was made physician to the Kings of Norway and Denmark, and died there in 1652. He has left several Tracts on Medical Subjects.

FABRICIUS, Philip, Conrad, professor of medicine at Helmstadt, was author of several useful works in anatomy and surgery. His first treatise, "Idea Anatomes Practicæ," 1741, contained some new directions in the Art of Injection, and described several branches of the Portio Dura, &c. In another work he has some good observations on the Abuse of Trepanning.

FABRICIUS, William, better known by the name of *Hildanus*, from Hilden, in Switzerland, where he was born in 1560. He repaired to Lausanne, to complete his knowledge of surgery, at the age of twenty-six; and distinguished himself there by his assiduity, and the successful treatment of many difficult cases. He studied medicine also, and went to practise both arts at Payenne in 1605; but ten years after was invited to Berne by the senate, who granted him a pension. In the latter part of his life, severe illness prevented his professional exertions, which had procured him general esteem, and high reputation. His death occurred in 1634. His works were written in German, but have been mostly translated into Latin. He published five "Centuries of Observations," which present many curious facts, as also several instruments invented by him.

FACE. The lower and anterior part of the cranium, or skull.

FA'CIAL. Belonging to the face; as facial nerve, &c.

FA'CIAL NERVE. *Nervus facialis. Portio dura* of the auditory nerve. These nerves are two in number, and are properly the eighth pair: but are commonly called the seventh, being reckoned with the auditory, which is the portio mollis of the seventh pair. They arise from the fourth ventricle of the brain, pass through the petrous portion of the temporal bone to the face, where they form the pes anserinus, which supplies the integuments of the face and forehead.

FA'CIES HIPPOCRA'TICA. That particular disposition of the features which immediately precedes the stroke of death is so called, because it has been so admirably described by Hippocrates.

Fa'cies ru'bra. See *Gutta rosacea.*

FACTI'TIOUS. A term applied to any thing which is made by art, in opposition to that which is native, or found already made in nature.

FA'CULTY. *Facultas.* The power or ability by which any action is performed.

FÆ'CES. The plural of *fæx.* The alvine excretions.

FÆ'CULA. (Diminutive of *fæx.*) A substance obtained by bruising or grinding certain vegetables in water. It is that part which, after a little, falls to the bottom. The fæcula of plants differs principally from gum or mucus in being insoluble in cold water, in which it falls with wonderful quickness. There are few plants which do not contain fæcula; but the seeds of gramineous and leguminous vegetables, and all tuberose roots contain it most plentifully.

FÆX. The alvine excretions are called *fæces.*

FAGA'RA. (From *fagus*, the beech, which it resembles.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria.* Order, *Monogynia.*

Faga'ra ma'jor. See *Fagara plerota.*

Faga'ra octa'ndra. The systematic name of the plant which affords *Tacamahaca*, which is a resinous substance that exudes both spontaneously, and when incisions are made into the stem of this tree: *Fagara foliolis tomentosis*, of Linnæus, and not as was formerly supposed from the *Populus balsamifera Linnæi.* Two kinds of a tacamahaca are met with in the shops. The best, called, from its being collected in a kind of gourd shell, tacamahaca in shells, is somewhat unctuous and soft, of a pale yellowish or greenish colour, a bitterish aromatic taste, and a fragrant delightful smell, approaching to that of lavender and ambergris. The more common sort is in semi-transparent grains, of a whitish, yellowish, brownish, or greenish colour, and of a less grateful smell than the former. Tacamahaca was formerly in high estimation as an ingredient in warm stimulating plasters; and although seldom used internally, it may be given with advantage as a corroborant and astringent balsamic.

Faga'ra plero'ta. *Fagara major. Castana Luzonis. Cubebis. Fagara plerota* of Linnæus. A plant found in the Philippine islands. The berries are aromatic, and, according to Avicenna, heating, drying, good for cold, weak stomachs, and astringent to the bowels.

Fagopy'rum. (From φαγος, the beech, and πυρος, wheat; because its seeds were supposed to resemble the mast, *i. e.* fruit of beech.) See *Polygonum fagopyrum.*

Fagotri'ticum. See *Polygonum fagopyrum.*

FA'GUS. (From φαγω, to eat; its nut being one of the first fruits used by man.)

1. The name of a genus of plants in the

Linnæan system. Class, *Monœcia.* Order, *Polyandria.*

2. The pharmacopœial name of the beech. See *Fagus sylvatica.*

Fa'gus casta'nea. The systematic name of the chesnut-tree. *Castanea. Lopima. Mota. Glans Jovis Theophrasti.* Jupiter's acorn, and Sardinian acorn. The common chesnut. The fruit of this plant, *Fagus castanea: foliis lanceolatis, acuminato-serratis, subtus nudis,* of Linnæus, are much esteemed as an article of luxury, after dinner. Toasting renders them more easy of digestion; but, notwithstanding, they must be considered as improper for weak stomachs. They are moderately nourishing, as containing sugar, and much farinaceous substance.

Fa'gus sylva'tica. The systematic name of the beech tree. *Fagus.* Also called *Oxya, Balanda, Valanida.* The beech-tree. The fruit and interior bark of this tree, *Fagus sylvatica; foliis ovatis, obsolete serratis,* of Linnæus, are occasionally used medicinally, the former in obstinate head-ache, and the latter in the cure of hectic fever. The oil expressed from beech-nuts is supposed to destroy worms; a child may take two drachms of it night and morning; an adult, an ounce. The poor people in Silesia use this oil instead of butter.

Fainting. See *Syncope.*

Fairburn water. A sulphureous water in the county of Ross, in the north of England.

FA'LCIFORM PRO'CESS. (*Falciformis;* from *falx,* a scythe, and *forma,* resemblance.) The falx. A process of the dura mater, that arises from the cristi galli, separates the hemispheres of the brain, and terminates in the tentorium.

Falde'lla. Contorted lint, used for compresses.

Falling sickness. See *Epilepsia.*

Fallopian tube. See *Tuba Fallopiana.*

Fallopian ligament. See *Poupart's ligament.*

FALLOPIUS, Gabriel, a physician of Modena, was born about the year 1523. He showed early great zeal, in anatomy, botany, chemistry, and other branches of knowledge; and after studying in Italy, travelled to other countries for his improvement. In 1548, he was appointed professor of anatomy at Pisa, and three years after at Padua; where he also taught botany, but with less celebrity. His death happened in 1563. He distinguished himself, not only as an anatomist, but also in medicine and surgery. Douglas has characterized him, as highly systematic in teaching, successful in treating diseases, and expeditious in operating. Some of the discoveries, to which he laid claim, appear to have been anticipated; as for instance, the tubes, proceeding from the uterus, though generally called after him *Fallopian.* However, he has the merit of recovering many of the observtions of the antients, which had fallen into oblivion. His "Observationes Anatomicæ," published in 1561, was one of the best works of the 16th century; in this some of the errors, which had escaped his master, Vesalius, are modestly pointed out. Many other publications, ascribed to him, were printed after his death; some of which are evidently spurious.

FALX. See *Falciform process.*

Fa'mes cani'na. See *Bulimia.*

Famigerati'ssimum empla'strum. (From *famigeratus,* renowned; from *fama,* fame, and *gero,* to bear; so named from its excellence.) A plaster used in intermittent fevers, made of aromatic, irritating substances, and applied to the wrists.

FA'RFARA. (From *farfarus,* the white poplar; so called because its leaves resemble those of the white poplar.) See *Tussilago.*

FARI'NA. (From *far,* corn, of which it is made.) Meal, or flour. A term given to the pulverulent and glutinous part of wheat, and other seeds, which is obtained by grinding and sifting. It is highly nutritious, and consists of gluten, starch, and mucilage. See *Triticum.*

FARINA'CEA. (From *farina,* flour.) This term includes all those substances, employed as aliment, called cerealia, legumina, and nuces oleosæ.

FARINA'CEOUS. A term given to all articles of food which contain *farina.* See *Farina.*

Farina'rium. See *Alica.*

Fa'rreus. (From *far,* corn.) Scurfy. An epithet of urine, where it deposits a branny sediment.

FA'SCIA. (From *fascis,* a bundle; because, by means of a band, materials are collected into a bundle.) *Ligatio. Ligatura. Alligatura.* A bandage, fillet, or roller.

2. The aponeurotic expansions of muscles, which bind parts together, are termed *fasciæ.*

FA'SCIA LA'TA. A thick and strong tendinous expansion, sent off from the back, and from the tendons of the glutei and adjacent muscles, to surround the muscles of the thigh. It is the thickest on the outside of the thigh and leg, but towards the inside of both becomes gradually thinner. A little below the trochanter major, it is firmly fixed to the linea aspera; and, farther down, to that part of the head of the tibia that is next the fibula, where it sends off the tendinous expansion along the outside of the leg. It serves to strengthen the action of the muscles, by keeping them firm in their proper places when in action, particularly the tendons that pass over the joints where this membrane is thickest.

Fascia'lis. (*Fascialis,* sc. *musculus.*) See *Tensor vaginæ femoris.*

Fascia′tio. (From *fascia*, a fillet.) The binding up any diseased or wounded part with bandages.

FASCI′CULUS. (From *fascis*, a bundle.) A handful.

FAT. *Adeps.* A concrete oily matter contained in the cellular membrane of animals, of a white, or yellowish colour, with little or no smell, nor taste. It differs in different animals in solidity, colour, taste, &c. and likewise in the same animal at different ages. In infancy it is white, insipid, and not very solid; in the adult it is firm and yellowish, and in animals of an advanced age, its colour is deeper, its consistence various, and its taste in general stronger. Fat meat is nourishing to those that have strong digestive powers. It is used externally, as a softening remedy, and enters into the composition of ointments and plasters.

Fatu′itas. (From *futuus*, silly.) Foolishness. A synonym of *Amentia*.

FAU′CES. (*Faux*, pl. *fauces.*) *Isthmion. Amphibranchia.* A cavity behind the tongue, palatine arch, uvula, and tonsils: from which the pharynx and larynx proceed.

Fau′fel. Terra japonica, or catechu.

Fava′go austra′lis. (From *favus*, a honey-comb, from its resemblance to a honey-comb.) A species of bastard sponge.

Fa′vus. A honey-comb. A species of achor, or foul ulcer.

FE′BRES. An order in the class *pyrexiæ* of Cullen, characterized by the presence of pyrexia, without primary local affection.

FEBRI′CULA. (Dim. of *febris*, a fever.) A term employed to express a slight degree of symptomatic fever.

Febri′fuga. (From *febrem fugare*, to drive away a fever.) The plant fever-few; lesser centaury.

FE′BRIFUGE. (*Febrifuga*, from *febris*, a fever, and *fugo*, to drive away.) A medicine that possesses the property of abating the violence of any fever.

Febri′fugum cræ′nii. Regulus of antimony.

Febri′fugum o′leum. Febrifuge oil. The flowers of antimony, made with sal-ammoniac and antimony sublimed together, and exposed to the air, when they deliquesce.

Febri′fugus pul′vis. Febrifuge powder. The Germans give this name to the pulvis stypticus Helvetii. In England, a mixture of oculi cancrorum and emetic tartar, in the proportion of half a drachm and two grains, has obtained the same name; in fevers it is given in doses of gr. iii. to iv.

Febri′fugus sal. Regenerated marine salt.

Febri′fugus spi′ritus domini Clut′ton. Mr. Clutton's febrifuge spirit. An imperfect ether, which is sometimes given diluted in water, as a common drink in fevers.

FE′BRIS. (*Febris, -is*, f. from *ferveo*, to burn.) A fever. A disease characterized by an increase of heat, an accelerated pulse, a foul tongue and an impaired state of several functions of the body.

Fe′bris a′lba. See *Chlorosis*.

Fe′bris amphimeri′na. A quotidian, or remittent fever.

Fe′bris angino′sa. The scarlatina anginosa.

Fe′bris aphtho′sa. An aphthous fever.

Fe′bris a′rdens. A burning inflammatory fever.

Fe′bris asso′des. A tertian fever, with extreme restlessness.

Fe′bris autumna′lis. An autumnal or bilious fever.

Fe′bris bullo′sa. The pemphigus, or vesicular fever.

Fe′bris cacato′ria. An intermittent, with diarrhœa.

Fe′bris ca′rcerum. The prison fever.

Fe′bris catarrha′lis. The catarrhal fever.

Fe′bris chole′rica. A fever with bilious diarrhœa.

FE′BRIS CONTI′NUA. A continued fever. A division of the order *febres*, in the class *pyrexiæ* of Cullen. Continued fevers have no intermission, but exacerbations come on usually twice in one day. The genera of continued fever are: 1. *Synocha*, or inflammatory fever, known by increased heat; pulse frequent, strong, and hard; urine high coloured; senses not much impaired. See *Synocha*. 2. *Typhus*, or putrid-tending fever, which is contagious, and is characterized by moderate heat; quick, weak, and small pulse; senses much impaired, and great prostration of strength. This genus has two species; *Typhus petechialis*, attended with petechiæ; and *Typhus icterodes*, or yellow fever; and of the former there are two varieties; *Typhus mitior*, or nervous fever; and *Typhus gravior*, or putrid fever. See *Febris nervosa*, and *Typhus*. 3. *Synochus*, or mixed fever. See *Synochus*.

Fe′bris elo′des. A fever with continual and profuse sweating.

Fe′bris epi′ala. A fever with a continual sense of cold.

Fe′bris erysipelato′sa. See *Erysipelas*.

Fe′bris exanthema′tica. Fever with eruption.

Fe′bris fla′va. The yellow fever.

FE′BRIS HE′CTICA. A genus of disease in the class *pyrexiæ*, and order *febris* of Cullen. It is known by exacerbations at noon, but greater in the evening, with slight remissions in the morning, after nocturnal sweats; the urine depositing a furfuraceo-lateritious sediment; appetite good; thirst moderate. Hectic fever is symptomatic of chlorosis, scrophula, phthisis, diseased viscera, &c.

Fe′bris hunga′rica. A species of tertian fever.

Fe'bris hydro'des. A fever with profuse sweats.

Fe'bris inflammato'ria. See *Synocha.*

Fe'bris castre'nsis. A camp fever, generally typhus.

FE'BRIS INTERMI'TTENS. An intermittent fever, or ague. A division of the order *febres* of Cullen, in the class *pyrexiæ.* Intermittent fevers are known by cold, hot, and sweating stages, in succession, attending each paroxysm, and followed by an intermission or remission. There are three genera of intermitting fevers and several varieties.

1. *Intermittens quotidiana.* A quotidian ague. The paroxysms return in the morning, at an interval of about twenty-four hours.

2. *Intermittens tertiana.* A tertian ague. The paroxysms commonly come on at midday, at an interval of about forty-eight hours.

3. *Intermittens quartana.* A quartan ague. The paroxysms come on in the afternoon, with an interval of about seventy-two hours. The tertian ague is most apt to prevail in the spring, and the quartan in autumn.

Of the quotidian, tertian, and quartan intermittents, there are several varieties and forms; as the double tertian, having a paroxysm every day, with the alternate paroxysms, similar to one another. The double tertian, with two paroxysms every other day. The triple tertian, with two paroxysms on one day, and another on the next. The double quartan, with two paroxysms on the first day, none on the second and third, and two again on the fourth day. The double quartan, with a paroxysm on the first day, another on the second, but none on the third. The triple quartan, with three paroxysms every fourth day. The triple quartan, with a paroxysm every day, every fourth paroxysm being similar.

When these fevers arise in the spring of the year, they are called vernal; and when in the autumn, they are known by the name of autumnal. Intermittents often prove obstinate, and are of long duration, in warm climates; and they not unfrequently resist every mode of cure, so as to become very distressing to the patient: and by the extreme debility which they are thereby induce, often give rise to other chronic complaints.

It seems to be pretty generally acknowledged, that marsh miasmata, or the effluvia, arising from stagnant water, or marshy ground, when acted upon by heat, are the most frequent exciting cause of this fever. In marshes, the putrefaction of both vegetable and animal matter is always going forward, it is to be presumed; and hence it has been generally conjectured, that vegetable and animal putrefaction imparted a peculiar quality to the effluvia arising from thence. We are not yet acquainted with all the circumstances, which are requisite to render marsh miasma productive of the intermittents; but it may be presumed that a moist atmosphere has a considerable influence in promoting its action. A watery poor diet, great fatigue, long watching, grief, much anxiety, exposure to cold, lying in damp rooms or beds, wearing damp linen, the suppression of some long-accustomed evacuation, or the recession of eruptions, have been ranked among the exciting causes of intermittents; but it is more reasonable to suppose that these circumstances act only by inducing that state of the body, which predisposes to these complaints. By some, it has been imagined that an intermittent fever may be communicated by contagion; but this supposition is by no means consistent with general observation.

One peculiarity of this fever is, its great susceptibility of a renewal from very slight causes, as from the prevalence of an easterly wind, even without the repetition of the original exciting cause. It would appear that a predisposition is left in the habit, which favours the recurrence of the complaint. In this circumstance, intermittents differ from most other fevers, as it is well known, that after a continued fever has once occurred, and been removed, the person so affected is by no means so liable to a fresh attack of the disorder, as one in whom it had never taken place.

We have not yet attained a certain knowledge of the proximate cause of an intermittent fever, but a deranged state of the stomach and primæ viæ is that which is most generally ascribed.

Each paroxysm of an intermittent fever is divided into three different stages, which are called the *cold*, the *hot*, and the *sweating stages* or *fits.*

The *cold* stage commences with languor, a sense of debility and sluggishness in motion, frequent yawning and stretching, and an aversion to food. The face and extremities become pale, the features shrink, the bulk of every external part is diminished, and the skin over the whole body appears constricted, as if cold had been applied to it. At length the patient feels very cold, and universal rigors come on with pains in the head, back, loins, and joints, nausea and vomiting of bilious matter; the respiration is small, frequent and anxious; the urine is almost colourless; sensibility is greatly impaired; the thoughts are somewhat confused; and the pulse is small, frequent and often irregular. In a few instances, drowsiness and stupor have prevailed in so high a degree as to resemble coma or apoplexy; but this is by no means usual.

These symptoms abating after a short time, the second stage commences with an increase of heat over the whole body, redness of the face, dryness of the skin, thirst, pain in the head, throbbing in the temples, anxiety and restlessness; the respiration is fuller and more free, but still frequent; the tongue is furred, and the pulse has become regular, hard and full. If the attack has been very severe, then perhaps delirium will arise.

When these symptoms have continued for some time, a moisture breaks out on the forehead, and by degrees becomes a sweat, and this, at length, extends over the whole body. As this sweat continues to flow, the heat of the body abates, the thirst ceases, and most of the functions are restored to their ordinary state. This constitutes the third stage.

It must, however, be observed, that in different cases these phenomena may prevail in different degrees, and their mode of succession vary; that the series of them may be more or less complete; and that the several stages, in the time they occupy, may be in different proportions to one another.

Such a depression of strength has been known to take place on the attack of an intermittent, as to cut off the patient at once; but an occurrence of this kind is very uncommon.

Patients are seldom destroyed in intermittents from general inflammation, or from a fulness of the vessels either of the brain or of the thoracic viscera, as happens sometimes in a continued fever; but when they continue for any length of time, they are apt to induce other complaints, such as a loss of appetite, flatulency, scirrhus of the liver, dropsical swellings, and general debility, which in the end now and then prove fatal. In warm climates, particularly, intermittents are very apt to terminate in this manner, if not speedily removed; and in some cases, they degenerate into continued fevers. When the paroxysms are of short duration, and leave the intervals quite free, we may expect a speedy recovery; but when they are long, violent, and attended with much anxiety and delirium, the event may be doubtful. Relapses are very common to this fever at the distance of five or six months, or even a year; autumnal intermittents are more difficult to remove than vernal ones, and quartans more so than the other types

Dissections of those who have died of an interment, show a morbid state of many of the viscera of the thorax and abdomen; but the liver, and organs concerned in the formation of bile, as likewise the mesentery, are those which are usually most affected.

The treatment of an intermittent fever resolves itself into those means, which may be employed during a paroxysm, to arrest its progress, or to mitigate its violence; and those, which may prevent any return, and effect a permanent cure: this forms of course the more important part of the plan; but it is sometimes necessary to palliate urgent symptoms; and it is always desirable to suspend a paroxysm, if possible, not only to prevent mischief, but also that there may be more time for the use of the most effectual remedies. When therefore a fit is commencing, or shortly expected, we may try to obviate it by some of those means, which excite movements of an opposite description in the system: an emetic will generally answer the purpose, determining the blood powerfully to the surface of the body; or a full dose of opium, assisted by the pediluvium, &c.; ether also, and various stimulant remedies will often succeed, but these may perhaps aggravate, should they not prevent the fit; the cold bath, violent exercise, strong impressions on the mind, &c. have likewise been occasionally employed with effect. Should the paroxysm have already come on, and the cold stage be very severe, the warm bath, and cordial diaphoretics in repeated moderate doses may assist in bringing warmth to the surface: when on the contrary great heat prevails, the antiphlogistic plan is to be pursued; and it may be sometimes advisable, when an organ of importance is much pressed upon, to take some blood locally, or even from the general system, if the patient is plethoric and robust: and where profuse perspirations occur, acidulated drink may be exhibited, with a little wine to support the strength, keeping the surface cool at the same time. In the intermissions, in conjunction with a generous diet, moderate exercise, and other means calculated to improve the vigour of the system, tonics are the remedies especially relied upon. At the head of these we must certainly place the cinchona, which taken largely in substance, will seldom fail to cure the disease, where it is not complicated with visceral affection: in a quotidian an ounce at least should be given between the fits, in a tertian half as much more, and in a quartan two ounces. It will be generally better to clear out the primæ viæ before this remedy is begun with; and various additions may often be required, to make it agree better with the stomach and bowels, particularly aromatics and other stimulants, aperients or small doses of opium, according to circumstances. We must not be content with the omission of a single paroxysm, but continue it till the health appears fully established. In failure of the cinchona other vegetable tonics may be tried, as the salix, gentian, calumba, and other bitters; or the astringents, as tormentil, galls, &c.; or these variously combined with each other, or with aromatics. The mineral acids are often powerfully tonic, and the sulphuric has been of late stated to have proved very successful in the removal of this disease. Some metallic preparations are also highly efficacious, particularly the liquor arsenicalis, which however is too hazardous a remedy to be employed indiscriminately; it must be given in small doses two or three times a day, and its effects assiduously watched. The sulphate of zinc, and chalybeates may be used more freely alone, or preferably joined with bitters. Where visceral disease attends, we can hardly succeed in curing the ague, till this be removed: a state of congestion, or inflammatory tendency, may require local bleeding, blistering, purging, &c.; and when there is a more fixed obstruction, particularly in the liver, the cautious use of mercury will be most likely to avail.

Fe′bris la′ctea. Milk fever.

Fe′bris le′nta. A slow fever.

Fe′bris lenticula′ris. A species of petechial fever.

Fe′bris mali′gna. The malignant fever.

Fe′bris milia′ris. The miliary fever.

Fe′bris morbillo′sa. The measles.

FE′BRIS NERVO′SA. *Febris lenta nervosa.* The nervous fever. A variety of typhus, the *typhus mitior* of Cullen, but by many considered as a distinct disease. It mostly begins with loss of appetite, increased heat and vertigo; to which succeed nausea, vomiting, great langour, and pain in the head, which is variously described, by some like cold water pouring over the top, by others a sense of weight. The pulse, before little increased, now becomes quick, febrile, and tremulous; the tongue is covered with a white crust, and there is great anxiety about the præcordia. Towards the seventh or eighth day, the vertigo is increased, and tinnitus aurium, cophosis, delirium, and a dry and tremulous tongue, take place. The disease mostly terminates about the fourteenth or twentieth day. See *Typhus.*

Fe′bris nosocomio′rum. The fever of hospitals.

Fe′bris palu′stris. The marsh fever.

Fe′bris pe′stilens. The plague.

Fe′bris petechia′lis. Fever with purple spots.

Fe′bris pu′trida. See *Typhus.*

Fe′bris scarlati′na. Scarlet fever.

Fe′bris sudato′ria. Sweating fever.

Fe′bris sy′nocha. See *Synocha.*

Fe′bris typho′des. See *Typhus.*

Fe′bris variolo′sa. A variolous or small-pox fever.

Fe′bris urtica′ria. Fever with nettle-rash.

Fe′bris vesiculo′sa. See *Erysipelas.*

Fe′cula. See *Fæcula.*

Fel. See *Bile.*

Fel natu′ræ. See *Aloe.*

Fel-wort. So called from its bitter taste like bile. See *Gentiana.*

Felli′culus. The gall bladder.

Felli′flua pa′ssio. A name given to cholera.

Felon. See *Paronychia.*

Fe′men. (*Quasi ferimen,* from *fero,* to bear; so called because it is the chief support of the body.) The thigh.

Femora′lis arte′ria. A continuation of the external iliac along the thigh, from Poupart's ligament to the ham.

Fe′moris os. See *Femur.*

FE′MUR. (*Femur,-moris,* n.) *Os femoris.* The thigh-bone. A long cylindrical bone, situated between the pelvis and tibia. Its upper extremity affords three considerable processes; these are, the head, the trochanter major, and trochanter minor. The head, which forms about two-thirds of a sphere, is turned inwards, and is received into the acetabulum of the os innominatum, with which it is articulated by enarthrosis. It is covered by a cartilage, which is thick in its middle part, and thin at its edges, but which is wanting in its lower internal part, where a round spongy fossa is observable, to which the strong ligament, usually, though improperly called the *round* one, is attached. This ligament is about an inch in length, flattish, and of a triangular shape, having its narrow extremity attached to the fossa just described, while its broader end is fixed obliquely to the rough surface near the inner and anterior edge of the acetabulum of the os innominatum, so that it appears shorter internally and anteriorly than it does externally and posteriorly.

The head of the os femoris is supported obliquely, with respect to the rest of the bone, by a smaller part, called the *cervix,* or *neck,* which, in the generality of subjects, is about an inch in length. At its basis we observe two oblique ridges, which extend from the trochanter major to the trochanter minor. Of these ridges, the posterior one is the most prominent. Around this neck is attached the capsular ligament of the joint, which likewise adheres to the edge of the cotyloid cavity, and is strengthened anteriorly by many strong ligamentous fibres, which begin from the lower and anterior part of the ilium, and spreading broader as they descend, adhere to the capsular ligament, and are attached to the anterior oblique ridge at the bottom of the neck of the femur. Posteriorly and externally, from the basis of the neck of the bone, a large unequal protuberance stands out, which is the *trochanter major.* The upper edge of this process is sharp and pointed posteriorly, but is more obtuse anteriorly. A part of it is rough and unequal, for the insertion of the muscles; the rest is smooth, and covered with a thin cartilaginous crust, between which and the tendon of the glutæus maximus that slides over it, a large bursa mucosa is interposed. Anteriorly, at the root of this process, and immediately below the bottom of the neck, is a small process called *trochanter minor.* Its basis is nearly triangular, having its two upper angles turned towards the head of the femur and the great trochanter, while its lower angle is placed towards the body of the bone. Its summit is rough and rounded. These two processes have gotten the name of *trochanters,* from the muscles that are inserted into them being the principal instruments of the rotatory motion of the thigh. Immediately below these two processes the body of the bone may be said to begin. It is smooth and convex before, but is made hollow behind by the action of the muscles. In the middle of this posterior concave surface is observed a rough ridge, called *linea aspera,* which seems to originate from the trochanters, and extending downwards, divides at length into two branches, which terminate in the tuberosities near the condyles. At the upper part of it, blood-vessels pass to the internal substance of the bone, by a hole that runs obliquely upwards.

The lower extremity of the os femoris is larger than the upper one, and somewhat flattened, so as to form two surfaces, of which the anterior one is broad and convex, and the posterior one narrower and slightly concave. This end of the bone terminates in two large protuberances, called *condyles,* which are united before so as to form a pulley, but are separated behind by a considerable cavity, in which the crural vessels and nerves are placed secure from the compression to which they would otherwise be exposed in the action of bending the leg. Of these two condyles, the external one is the largest; and when the bone is separated from the rest of the skeleton, and placed perpendicularly, the internal condyle projects less forwards, and descends nearly three-tenths of an inch lower than the external one; but in its natural situation, the bone is placed obliquely, so that both condyles are then nearly on a level with each other. At the side of each condyle, externally, there is a tuberosity, the situation of which is similar to that of the condyles of the os humeri. The two branches of the linea aspera terminate in these tuberosities, which are rough, and serve for attachment of ligaments and muscles.

Fénnel. See *Anethum fœniculum.*

Fénnel, hog's. See *Peucedanum.*

FENE'STRA OVA'LIS. An oblong or elliptical foramen, between the cavity of the tympanum and the vestibulum of the ear. It is shut by the stapes.

FENE'STRA ROTU'NDA. A round foramen, leading from the tympanum to the cochlea of the ear. It is covered by a membrane in the fresh subject.

Fénugreek. See *Trigonella fœnum græcum.*

FE'RINE. (*Ferinus,* sc. *morbus,* savage or brutal.) A term occasionally applied to any malignant or noxious disease.

FERMENTA'TION. *Fermentatio.* A spontaneous commotion in a vegetable substance, by which its properties are totally changed. There are several circumstances required in order that fermentation may proceed: such are, 1. A certain degree of fluidity: thus, dry substances do not ferment at all. 2. A certain degree of heat. 3. The contact of air. Chemists, after Boerhaave, have distinguished three kinds of fermentation: the *spirituous,* which affords ardent spirit; the *acetous,* which affords vinegar, or acetic acid; and the *putrid* fermentation, or putrefaction, which produces volatile alkali. The conditions necessary for spirituous fermentation are, 1. A saccharine mucilage. 2. A degree of fluidity slightly viscid. 3. A degree of heat between 55 and 65 of Fahrenheit. 4. A large mass, in which a rapid commotion may be excited. When these four conditions are united, the spirituous fermentation takes place, and is known by the following characteristic phenomena: 1. An intestine motion takes place. 2. The bulk of the mixture then becomes augmented. 3. The transparency of the fluid is diminished by opake filaments. 4. Heat is generated. 5. The solid parts mixed with the liquor rise and float in consequence of the disengagement of elastic fluid. 6. A large quantity of carbonic acid gas is disengaged in bubbles. All these phenomena gradually cease in proportion as the liquor loses its sweet and mild taste, and it becomes brisk, penetrating, and capable of producing intoxication. In this manner wine, beer, cider, &c. are made. All bodies which have undergone the spirituous fermentation are capable of passing on to the acid fermentation; but although it is probable that the acid fermentation never takes place before the body has gone through the spirituous fermentation, yet the duration of the first is frequently so short and imperceptible, that it cannot be ascertained. Besides the bodies which are proper for spirituous fermentation, this class includes all sorts of fæcula boiled in water. The conditions required for the acid fermentation are, 1. A heat from 70 to 85 degrees of Fahrenheit. 2. A certain degree of liquidity. 3. The presence of atmospheric air. 4. A moderate quantity of fermentable matter. The phenomena which accompany this fermentation, are an intestine motion, and a considerable absorption of air. The transparent liquor becomes turbid, but regains its limpidity when fermentation is over. The fermented liquor now consists, in a great measure, of a peculiar acid, called the acetic acid, or vinegar. Not a vestige of spirit remains, it being entirely decomposed; but the greater the quantity of spirit in the liquor, previous to the fermentation, the greater will be the quantity of true vinegar obtained. See also *Putrefaction.*

FERME'NTUM. (*Quasi fervimentum,* from *ferveo,* to work.) Yest.

Fern, male. See *Polypodium filix mas.*

Fern, female. See *Pteris aquilina.*

FERNEL, JOHN, was born at Claremont, near the end of the 15th century. He went at the age of 19 to prosecute his studies at Paris, and distinguished himself so much, that, after taking the degree of master of arts, he was chosen professor of dialectics in his college. His application then became intense, till a quartan ague obliged him to seek his native air: and on his return to Paris, he determined on the medical profession, and taught philosophy for his support, till in 1530, he took his doctor's degree. Soon after he married, and speedily got into extensive practice; and at length was made physician to the Dauphin, who afterwards became Henry II. He was obliged to accompany that monarch in his campaigns, yet he still, though at the age of sixty, seldom passed a day without writing. But in 1558, having lost his wife of a fever, he did not long survive her. His works are numerous on philosophical, as well as medical subjects: of the latter the most esteemed were his "Medicina," dedicated to Henry II., and a posthumous treatise on fevers.

Ferrame'ntum. An instrument made of iron.

Fe'rri alkali'ni li'quor. Solution of alkaline iron. "Take of iron, two drachms and a half; nitric acid, two fluid-ounces: distilled water, six fluid-ounces; solution of subcarbonate of potash, six fluid-ounces. Having mixed the acid and water, pour them upon the iron, and when the effervescence has ceased, pour off the clear acid solution; add this gradually, and at intervals, to the solution of subcarbonate of potash, occasionally shaking it, until it has assumed a deep brown-red colour, and no further effervescence takes place. Lastly, set it by for six hours, and pour off the clear solution." This preparation was first described by Stahl, and called tinctura martis alkalina, and is now introduced in the Lond. Pharm. as affording a combination of iron distinct from any other, and often applicable to practice. The dose is from half a drachm to a drachm.

Fe'rri carbo'nas. See *Ferri subcarbonas.*

Fe'rri limatu'ra purifica'ta. Purified iron filings. These possess tonic, astringent, and deobstruent virtues, and are calculated to relieve chlorosis and other diseases in which steel is indicated, where acidity in the primæ viæ abounds.

Fe'rri rubi'go. See *Ferri subcarbonas.*

Fe'rri subcarbo'nas. *Ferri carbonas. Ferrum præcipitatum,* formerly called *chalybis rubigo præparata* and *ferri rubigo.* Subcarbonate of iron. "Take of sulphate of iron, eight ounces; subcarbonate of soda, six ounces; boiling water, a gallon. Dissolve the sulphate of iron and subcarbonate of soda separately, each in four pints of water; then mix the solutions together and set it by, that the precipitated powder may subside; then having poured off the supernatant liquor, wash the subcarbonate of iron with hot water, and dry it upon bibulous paper in a gentle heat." It possesses mild corroborant and stimulating properties, and is exhibited with success in leucorrhæa, ataxia, asthenia, chlorosis, dyspepsia, rachitis, &c. Dose from two to ten grains.

Fe'rri su'lphas. Sulphate of iron; formerly called *sal martis, vitriolum martis, vitriolum ferri,* and lately *ferrum vitriolatum.* Green vitriol. "Take of iron, sulphuric acid, of each by weight, eight ounces; water, four pints. Mix together the sulphuric acid and water in a glass vessel, and add thereto the iron; then after the effervescence has ceased, filter the solution through paper, and evaporate it until crystals form as it cools. Having poured away the water, dry these upon bibulous paper." This is an excellent preparation of iron, and is exhibited, in many diseases, as a styptic, tonic, astringent, and anthelmintic. Dose from one grain to five grains.

FE'RRUM. (*Ferrum, -i,* neut. the etymology uncertain.) See *Iron.*

Fe'rrum ammonia'tum. Ammoniated iron; formerly known by the names of *flores martiales; flores salis ammoniaci martiales; ens martis; ens veneris Boylei; sal martis muriaticum sublimatum,* and lately by the title of *ferrum ammoniacale.* "Take of subcarbonate of iron, muriate of ammonia, of each a pound. Mix them intimately, and sublime by immediate exposure to a strong fire; lastly, reduce the sublimed ammoniated iron to powder." This preparation is astringent and deobstruent, in doses from 3 to 15 grs. or more in the form of bolus or pills, prepared with some gum. It is exhibited in most cases of debility, in chlorosis, asthenia, menorrhagia, intermittent fevers, &c. This or some other strong preparation of iron, as the Tinct. ferri muriatis, Mr. Cline is wont to recommend in scirrhous affections of the breast. See *Tinctura ferri ammoniati.*

Fe'rrum tartariza'tum. Tartarized iron. A tartrate of potash and iron; formerly called *tartarus chalybeatus; mars solubilis; ferrum potabile.* "Take of iron, a pound; supertartrate of potash, powdered, two pounds; water, a pint. Rub them together; and expose them to the air in a broad glass vessel for eight days, then dry the residue in a sand bath, and reduce it to a very fine powder. Add to this powder a pint more water, and expose it for eight days longer, then dry it, and reduce it to a very fine powder." Its virtues are astringent and tonic, and it forms in solution an excellent tonic fomentation to contusions, lacerations, distortions, &c. Dose from ten grains to half a drachm.

Fe'rsæ. The measles.

FE'RULA. The name of a genus of plants in the Linnæan system. Class *Pentandria.* Order, *Digynia.*

Fe'rula Africa'na galbani'fera. The galbanum plant.

Fe'rula assafœ'tida. The systematic name of the assafœtida plant. *Assafœtida.*

Hingiseh of the Persians. *Altiht* of the Arabians. By some thought to be the *σιλφιον*, vel, *οπος σιλφιου* of Dioscorides, Theophrastus, and Hippocrates. *Laser et laserpitium* of the Latins. Assafœtida gum resin. The plant which affords this gum resin, is the *Ferula assafœtida foliis alternatim sinuatis, obtusis,* of Linnæus. It grows plentifully on the mountains in the provinces of Chorassan and Laar, in Persia.

The process of obtaining it is as follows: the earth is cleared away from the top of the roots of the oldest plants; the leaves and stalks are then twisted away, and made into a covering, to screen the root from the sun; in this state the root is left for forty days, when the covering is removed, and the top of the root cut off transversely; it is then screened again from the sun for forty-eight hours, when the juice it exudes is scraped off, and exposed to the sun to harden. A second transverse section of the root is made, and the exudation suffered to continue for forty-eight hours, and then scraped off. In this manner it is eight times repeatedly collected in a period of six weeks. The juice thus obtained has a bitter, acrid, pungent taste, and is well known by its peculiar nauseous smell, the strength of which is the surest test of its goodness. This odour is extremely volatile, and of course the drug loses much of its efficacy by keeping. It is brought to us in large irregular masses, composed of various little shining lumps, or grains, which are partly of a whitish colour, partly reddish, and partly of a violet hue. Those masses are accounted the best which are clear, of a pale reddish colour, and variegated with a great number of elegant white tears. This concrete juice consists of two-thirds of gum and one-third of resin, and volatile oil, in which its taste and smell reside. It yields all its virtues to alkohol. Triturated with water, it forms a milk-like mixture, the resin being diffused by the medium of the gum. Distilled with water, it affords a small quantity of essential oil. It is the most powerful of all the fœtid gums, and is a most valuable remedy. It is most commonly employed in hysteria, hypocondriasis, some symptoms of dyspepsia, flatulent colics, and in most of those diseases termed nervous, but its chief use is derived from its antispasmodic effects; and it is thought to be the most powerful remedy we possess, for those peculiar convulsive and spasmodic affections, which often recur in the first of these diseases, both taken into the stomach and in the way of enema. It is also recommended as an emmenagogue, anthelmintic, antiasthmatic, and anodyne. Dr. Cullen prefers it as an expectorant to gum ammoniacum. Where we wish it to act immediately as an antispasmodic, it should be used in a fluid form, as that of tincture, from half a drachm to two drachms. When given in the form of a pill, or triturated with water, its usual dose is from 5 to 20 grs. When in the form of enema, one or two drachms are to be diffused in eight ounces of warm milk or water. It is sometimes applied externally as a plaster and stimulating remedy, in hysteria, &c.

Fe'rula mi'nor. All-heal of Æsculapius; this plant is said to be detergent.

Ferula'cca. The ferula galbanifera.

Fever. See *Febris.*

Feverfew. See *Matricaria.*

Fi'ber. (From *fiber*, extreme, because it resides in the extremities of lakes and rivers.) The beaver. *Castor fiber*, of Linnæus; it has two excretory follicles near the anus, filled with an unctuous substance called castor. See *Castor.*

FIBRE. *Fibra.* An anatomical term for a very simple filament supposed to be composed of earthy particles, connected together by an intermediate gluten. It is owing to the different arrangements of the fibres that the cellular structure, membranes, muscles, vessels, nerves, and, in short, every part of the body, except the fluids, are formed.

Fibre muscular. See *Muscular fibre.*

Fi'brine. The coagulable lymph is so termed by the French.

FI'BULA. (*Quasi figilula*; from *figo*, to fasten; so named because it joins together the tibia and the muscles.) A long bone of the leg, situated on the outer side of the tibia, and which forms, at its lower end, the outer ankle. Its upper extremity is formed into an irregular head, on the inside of which is a slightly concave articulating surface, which, in the recent subjects, is covered with cartilage, and receives the circular flat surface under the edge of the external cavity of the tibia. This articulation is surrounded by a capsular ligament, which is farther strengthened by other strong ligamentous fibres, so as to allow only a small motion backwards and forwards.—Externally, the head of the fibula is rough and protuberant, serving for the attachment of ligaments, and for the insertion of the biceps cruris muscle.—Immediately below it, on its inner side, is a tubercle, from which a part of the gastrocnemius internus has its origin. Immediately below this head the body of the bone begins. It is of a triangular shape, and appears as if it were slightly twisted at each end, in a different direction. It is likewise a little curved inwards and forwards. This curvature is in part owing to the action of muscles: and in part perhaps to the carelessness of nurses.—Of the three angles of the bone, that which is turned towards the tibia is the most prominent, and serves for the attachment of the interosseous ligament, which, in its structure and uses, resembles that of the fore-arm, and, like that, is a little interrupted above and below. The three surfaces of the bone are variously impressed by different muscles. About the middle of the posterior surface is observed a passage for the medullary vessels, slanting downwards. The lower end of the fibula is formed into a spongy, oblong head, externally rough and convex, internally smooth and covered with a thin cartilage, where it is received by the external triangular depression at the lower end of the tibia. This articulation, which resembles that of its upper extremity, is furnished with a capsular ligament, and farther strengthened by ligamentous fibres, which are stronger and more considerable than those before described. They extend from the tibia to the fibula, in an oblique direction, and are more easily discernible before than behind. Below this the fibula is lengthened out, so as to form a considerable process, called *malleolus externus*, or the outer ankle. It is smooth, and covered with cartilage on the inside, where it is contiguous to the astragalus, or first bone of the foot. At the lower and inner part of this process there is a spongy cavity, filled with fat; and a little beyond this, posteriorly, is a cartilaginous groove, for the tendons of the peroneus longus and peroneus brevis, which are here bound down by the ligamentous fibres that are extended over them.

The principal uses of this bone seem to be, to afford origin and insertion to muscles, and to contribute to the articulation of the leg with the foot.

Fica'ria. (From *ficus*, a fig, so called from its likeness.) The herb figwort, or pile-wort, the *ranunculus ficaria* of Linnæus.

Fica'tio. (From *ficus*, a fig.) Tubercles near the anus and pudenda.

Ficoide'a. *Ficoides.* Resembling a fig. A name of the houseleek, which is emollient.

FI'CUS. 1. A fleshy excresence about the anus, in figure resembling a fig.

2. The name of a genus of plants in the Linnæan system. Class, *Polygamia*. Order, *Dioecia*. The fig-tree.

Fi'cus ca'rica. The systematic name of the fig-tree. *Carica. Ficus. Ficus vulgaris. Ficus communis.* Συκη of the Greeks. The fig. The plant which affords this fruit is the *Ficus Carica* of Linnæus. French figs are, when completely ripe, soft, succulent, and easily digested, unless eaten in immoderate quantities, when they are apt to occasion flatulency, pain of the bowels, and diarrhœa. The dried fruit, which is sold in our shops, is pleasanter to the taste, and more wholesome and nutritive. They are directed in the *decoctum hordei compositum*, and in the *electuarium lenitivum*. Applied externally, they promote the suppuration of tumours; hence they have a place in maturating cataplasms; and are very convenient to apply to the gums, and, when boiled with milk, to the throat.

Fi'cus i'ndica. See *Lacca*.

Fidicina'les. (*Fidicinalis, sc. musculus.*) See *Lumbricales*.

FIENUS, Thomas, was son of a physician of Antwerp, and born in 1567. After studying at Leyden and Bologna, he was invited, at the age of 26, to be one of the medical professors at Louvaine, where he took his degrees. With the exception of one year, during which he attended the Duke of Bavaria, he remained in that office till his death in 1631. Besides his great abilities in medicine and surgery, he was distinguished for his knowledge of natural history, the learned languages, and the mathematics. He has left several works: the chief of which is termed "Libri Chirurgici XII." treating of the principal operations; it passed through many editions. His Father, *John*, was author of a well received treatise, "De Flatibus."

Figs. See *Ficus carica*.

Figwort. See *Ranunculus ficaria*.

Fila'go. Cud or cotton-weed; an astringent.

FI'LAMENT. (*Filamentum*; from *filum*, a thread.) A term applied in anatomy to a small thread-like portion adhering to any part, and frequently synonymous with fibre. See *Fibre*.

File'llum. (From *filum*, a thread, because it resembles a string.) The frænum of the penis.

File'tum. (From *filum*, a thread; named from its string-like appearance.) The frænum of the tongue.

Fili'cula. (Dim. of *filix*, fern; a small sort of fern; or from *filum*, a thread, which it resembles.) Common maiden-hair. See *Adianthum capillus Veneris*.

FILIPE'NDULA. (From *filum*, a thread, and *pendeo*, to hang; so named because the numerous bulbs of its roots hang, as it were, by small threads.) See *Spiræa filipendula*.

Filipe'ndula aqua'tica. Water-dropwort.

Fi'lius a'nte pa'trem. Any plant whose flower comes out before the leaf, as coltsfoot.

FI'LIX. (From *filum*, a thread; so called from its being cut, as it were, in slender portions, like threads.) Fern. See *Polypodium filix mas*.

Fi'lix aculea'ta. See *Polypodium aculeatum*.

Fi'lix fœ'mina. See *Pteris aquilina*.

Fi'lix flo'rida. See *Osmunda regalis*.

Fi'lix mas. See *Polypodium filix mas*.

FILTRA'TION. (*Filtratio*; from *filtrum*, a strainer.) A method of rendering fluids clear, by passing them through a porous solid, as the filtering stone, compact close linen, woollen cloths, or porous paper, which is generally used for this purpose, as a lining to a funnel, or other such vessel. Filtration is also performed on a principle somewhat different, as by immersing one end of a porous substance, as a piece of list, skein of cotton, or slip of thick paper, or other such substance, moistened in its whole length in the fluid, and allowing the other end of it to hang down, over the outside of the vessel. The fluid in this depending part drains out by its own gravity, and is supplied by capillary attraction from the portion next within the vessel, which is supplied in the same manner from the surface of the fluid, till the whole passes over, unless too deep, the list, &c. appearing to act as syphons.

FI′LTRUM. A filter, straining or filtering instrument.

Fi′lum arsenica′le. Corrosive sublimate.

FI′MBRIÆ. (*Fimbria*, a fringe. *Quasi finibria*; from *finis*, the extremity.) The extremities of the Fallopian tubes. See *Uterus.*

Finckle. See *Anethum fœniculum.*

Fine leaved water hemlock. See *Phellandrium aquaticum.*

Finochio. The Italian name of the sweet azorian fennel.

Fir-tree. See *Pinus.*

Fir, balsam of Gilead. See *Pinus balsamea.*

Fir, Canada. See *Pinus balsamea.*

Fir, Norway spruce. See *Pinus abies.*

Fir, Scotch. See *Pinus sylvestris.*

Fir, silver. See *Pinus picea.*

FIRE. *Ignis.* A very simple and active element, the principal agent in nature to balance the power and natural effect of attraction. The most useful acceptation of the word fire comprehends *heat* and *light.* There have been several theories proposed respecting fire, but no one as yet is fully established. See *Caloric* and *Light.*

Firmi′sium minera′lium. Antimony.

FISCHER, John Andrew, son of an apothecary at Erfurt, was born in 1667. He graduated there, and was appointed in succession to several professorships; but that of pathology and the practice of medicine he did not receive till the age of 48. He acquired considerable reputation in his profession; and he had been ten years physician to the court of Mayence; when he died in 1729. Among several minor works he was author of some of greater importance; as the "Consilia Medica," in three volumes, the "Responsa Practica," and a Synopsis of Medicine, facetiously termed "Ilias in Nuce."

Fish-glue. See *Ichthyocolla.*

FISSU′RA MA′GNA SY′LVII. The anterior and middle lobes of the cerebrum on each side are parted by a deep narrow sulcus, which ascends obliquely backwards from the temporal ala of the os sphenoides, to near the middle of the os parietale, and this sulcus is thus called.

FISSURE. *Fissura.* That species of fracture in which the bone is slit, but not completely divided.

Fistic-nut. See *Pistachia vera.*

FI′STULA. (*Quasi fusula*: from *fundo*, to pour out; or from its similarity to a pipe, or reed.) *Eligii morbus.* A term in surgery, applied to a long and sinuous ulcer that has a narrow opening, and which sometimes leads to a larger cavity; and has no disposition to heal. No technical term has been more misapplied: and no misinterpretation of a word has had worse influence in practice than this. Many simple healthy abscesses, with small openings, have too often been called *fistulous*; and, the treatment pursued has in reality at last rendered them so, and been the only reason of their not having healed.

Fistula′ria. (From *fistula*, a pipe: so called because its stalk is hollow.) A name for stavesacre.

Five-leaved grass. See *Potentilla reptans.*

Fixed air. See *Carbonic acid.*

FIXED BODIES. Chemists give this name to those substances which cannot be caused to pass by a strong rarefaction from the solid or liquid state to that of an elastic fluid.

Flag, sweet. See *Acorus calamus.*

Flag, yellow water. See *Iris pseudacorus.*

Fla′mmula. (Dim. of *flamma*, a fire, named from the burning pungency of its taste.) See *Ranunculus flammula.*

Fla′mmula jo′vis. See *Clematis recta.*

FLATULENT. Windy.

Flax-leaved daphne. See *Daphne Gnidium.*

Flax, purging. See *Linum catharticum.*

Flax, spurge. See *Daphne gnidium.*

Flea-wort. See *Plantago Psyllium.*

Fle′men. (From *flecto*, to incline downwards.) *Flegmen.* A tumour about the ankles.

Flere′sin. Gout.

FLE′XOR. The name of several muscles whose office it is to bend parts into which they are inserted.

Fle′xor accesso′rius digito′rum pe′dis. See *Flexor longus digitorum pedis.*

FLE′XOR BRE′VIS DIGITO′RUM PE′DIS, PERFORA′TUS, SUBLI′MIS. *Flexor brevis digitorum pedis perforatus* of Albinus. *Flexor brevis* of Douglas. *Flexor digitorum brevis, sive perforatus pedis* of Winslow. *Perforatus, seu flexor secundi internodii digitorum pedis* of Cowper, and *calcano sus-phalangettien commun* of Dumas. A flexor muscle of the toes, situated on the foot. It arises by a narrow, tendinous, and fleshy beginning, from the inferior protuberance of the os calcis. It likewise derives many of its fleshy fibres from the adjacent aponeurosis, and soon forms a thick belly, which divides into four portions. Each of these portions terminates in a flat tendon, the fibres of which decussate, to afford a passage to a tendon of the long flexor, and afterwards re-uniting, are inserted into the second phalanx of each or the four lesser toes. This muscle serves to bend the second joint of the toes.

FLE'XOR BRE'VIS MINI'MI DI'GITI PE'DIS. *Parathenar minor* of Winslow. This little muscle is situated along the inferior surface and outer edge of the metatarsal bone of the little toe. It arises tendinous from the basis of that bone, and from the ligaments that connect it to the os cuboides. It soon becomes fleshy, and adheres almost the whole length of the metatarsal bone, at the anterior extremity of which it forms a small tendon, that is inserted into the root of the first joint of the little toe. Its use is to bend the little toe.

FLE'XOR BRE'VIS PO'LLI'CIS MA'NUS. *Flexor secundi internodii* of Douglas. *Thenar* of Winslow. *Flexor primi et secundi ossis pollicis* of Cowper, and *Carpophalangien du pouce* of Dumas. This muscle is divided into two portions by the tendon of the flexor longus pollicis. The outermost portion arises tendinous from the anterior part of the os trapezoides and internal annular ligament. The second, or innermost, and thickest portion, arises from the same bone, and likewise from the os magnum, and os cuneiforme. Both these portions are inserted tendinous into the sesamoid bones of the thumb. The use of this muscle is to bend the second joint of the thumb.

FLE'XOR BRE'VIS PO'LLICIS PE'DIS. *Flexor brevis* of Douglas. *Flexor brevis pollicis* of Cowper, and *Tarsophalangien du pouce* of Dumas. A muscle of the great toe, that bends the first joint of that part. It is situated upon the metatarsal bone of the great toe, arises, tendinous from the under and anterior part of the os calcis, and from the under part of the os cuneiforme externum. It soon becomes fleshy and divisible into two portions which do not separate from each other till they have reached the anterior extremity of the metatarsal bone of the great toe, where they become tendinous, and then the innermost portion unites with the tendon of the abductor, and the outermost with that of the adductor pollicis. They adhere to the external os sesamoideum, and are finally inserted into the root of the first joint of the great toe. These two portions, by their separation, form a groove, in which passes the tendon of the flexor longus pollicis.

FLE'XOR CA'RPI RADIA'LIS. *Radialis internus* of Albinus and Winslow, and *Epitrochlo-metacarpien* of Dumas. This is a long thin muscle, situated obliquely at the inner and anterior part of the fore-arm, between the palmaris longus and the pronator teres. It arises tendinous from the inner condyle of the os humeri, and, by many fleshy fibres, from the adjacent tendinous fascia. It descends along the inferior edge of the pronator teres, and terminates in a long, flat, and thin tendon, which afterwards becomes narrower and thicker, and, after passing under the internal annular ligament, in a groove distinct from the other tendons of the wrist, it spreads wider again, and is inserted into the fore and upper part of the metacarpal bone that sustains the fore finger. It serves to bend the hand, and its oblique direction may likewise enable it to assist in its pronation.

FLE'XOR CA'RPI ULNA'RIS. *Ulnaris internus* of Winslow and Albinus. *Epitrochli-cubito carpien* of Dumas. A muscle situated on the cubit or fore-arm, that assists the former in bending the arm. It arises tendinous from the inner condyle of the os humeri, and, by a small fleshy origin, from the anterior edge of the olecranon. Between these two portions, we find the ulnar nerve passing to the fore-arm. Some of its fibres arise likewise from the tendinous fascia that covers the muscles of the fore-arm. In its descent, it soon becomes tendinous, but its fleshy fibres do not entirely disappear till it has reached the lower extremity of the ulna, where its tendon spreads a little, and, after sending off a few fibres to the external and internal and annular ligaments, is inserted into the os pisiforme.

FLE'XOR LO'NGUS DIGITO'RUM PE'DIS PROFU'NDUS PE'RFORANS. *Perforans seu flexor profundus* of Douglas, *Flexor digitorum longus, sive perforans pedis*, and *perforans seu flexor tertii internodii digitorum pedis* of Cowper, and *Tibio phalangetien* of Dumas. A flexor muscle of the toes, situated along the posterior part and inner side of the leg. It arises fleshy from the back part of the tibia, and, after running down to the internal ankle, its tendon passes under a kind of annular ligament, and then through a sinuosity at the inside of the os calcis. Soon after this it receives a small tendon from the flexor longus pollicis pedis, and about the middle of the foot it divides into four tendons, which pass through the slits of the flexor brevis digitorum pedis, and are inserted into the upper part of the last bone of all the lesser toes. About the middle of the foot, this muscle unites with a fleshy portion, which, from the name of its first describer, has been usually called *massa carnea Jacobi Sylvii*: it is also termed *Flexor accessorius digitorum pedis*. This appendage arises by a thin fleshy origin, from most part of the sinuosity of the os calcis, and likewise by a thin tendinous beginning from the anterior part of the external tubercle of that bone; it soon becomes all fleshy, and unites to the long flexor just before it divides into its four tendons. The use of this muscle is to bend the last joint of the toes.

FLE′XOR LO′NGUS PO′LLICIS MA′NUS. *Flexor longus pollicis* of Albinus. *Flexor tertii internodii* of Douglas. *Flexor tertii internodii sive longissimus pollicis* of Cowper, and *radio-phalangetien du pouce* of Dumas. This muscle is placed at the side of the flexor longus digitorum pedis, profundus, perforans, and is covered by the extensores carpi radiales. It arises fleshy from the anterior surface of the radius, immediately below the insertion of the biceps, and is continued down along the oblique ridge, which serves for the insertion of the supinator brevis, as far as the pronator quadratus. Some of its fibres spring likewise from the neighbouring edge of the interosseous ligament. Its tendon passes under the internal annular ligament of the wrist, and after running along the inner surface of the first bone of the thumb, between the two portions of the flexor brevis pollicis, goes to be inserted into the last joint of the thumb, being bound down in its way by the ligamentous expansion that is spread over the second bone. In some subjects we find a tendinous portion arising from the inner condyle of the os humeri, and forming a fleshy slip that commonly terminates near the upper part of the origin of this muscle from the radius. The use of this muscle is to bend the last joint of the thumb.

FLE′XOR LO′NGUS PO′LLICIS PE′DIS. This muscle is situated along the posterior part of the leg. It arises tendinous and fleshy a little below the head of the fibula, and its fibres continue to adhere to that bone almost to its extremity. A little above the heel it terminates in a round tendon, which, after passing in a groove formed at the posterior edge of the astragalus, and internal and lateral part of the os calcis, in which it is secured by an annular ligament, goes to be inserted into the last bone of the great toe, which it serves to bend.

FLE′XOR O′SSIS METACA′RPI PO′LLICIS. *Seu opponens pollicis* of Innes. *Opponens pollicis manus* of Albinus. *Flexor primi internodii* of Douglas. *Antithenar sive semi-interosseus pollicis* of Winslow, and *carpo phalangien du pouce* of Dumas. This muscle is situated under the abductor brevis pollicis, which it resembles in its shape. It arises tendinous and fleshy from the os scaphoides, and from the anterior and inner part of the internal annular ligament. It is inserted tendinous and fleshy into the under and anterior part of the first bone of the thumb. It serves to turn the first bone of the thumb upon its axis, and at the same time to bring it inwards opposite to the other fingers.

FLE′XOR PA′RVUS MI′NIMI DI′GITI. *Abductor minimi digiti, Hypothenar Riolani* of Douglas. *Hypothenar minimi digiti* of Winslow, and second *carpo-phalangien du petit doigt* of Dumas. The situation of this muscle is along the inner surface of the metacarpal bone of the little finger. It arises tendinous and fleshy from the hook-like process of the unciform bone, and likewise from the anterior surface of the adjacent part of the annular ligament. It terminates in a flat tendon, which is connected with that of the abductor minimi digiti, and inserted into the inner and anterior part of the upper end of the first bone of the little finger. It serves to bend the little finger, and likewise to assist the abductor.

FLE′XOR PROFU′NDUS PE′RFORANS. *Profundus* of Albinus. *Perforans* of Douglas. *Perforans vulgo profundus* of Winslow. *Flexor tertii internodii digitorum manus, vel perforatus manus* of Cowper, and *cubito-phalangetien commun* of Dumas. This muscle is situated on the fore-arm, immediately under the perforatus, which it greatly resembles in its shape. It arises fleshy from the external side, and upper part of the ulna, for some way downwards, and from a large portion of the interosseus ligament. It splits into four tendons a little before it passes under the annular ligament of the wrist, and these pass through the slit in the tendons of the flexor sublimis, to be inserted into the fore and upper part of the third or last bone of all the four fingers, the joint of which they bend.

FLE′XOR SUBLI′MIS PERFO′RATUS. This muscle, which is the *perforatus* of Cowper, Douglas, and Winslow, is by Albinus and others named *sublimis.* It has gotten the name of perforatus from its tendons being perforated by those of another flexor muscle of the finger, called the *perforans.* They who give it the appellation of *sublimis,* consider its situation with respect to the latter, and which, instead of *perforans,* they name *profundus.* It is a long muscle, situated most commonly at the anterior and inner part of the fore-arm, between the palmaris longus and the flexor carpi ulnaris; but, in some subjects, we find it placed under the former of these muscles, between the flexor carpi ulnaris and the flexor carpi radialis. It arises, tendinous and fleshy, from the inner condyle of the os humeri, from the inner edge of the coronoid process of the ulna, and from the upper and fore part of the radius, down to near the insertion of the pronator teres. A little below the middle of the fore-arm, its fleshy belly divides into four portions, which degenerate into as many round tendons, that pass all together under the internal annular ligament of the wrist, after which they separate from each other, become thinner and flatter, and running along the palm of the hand, under the aponeurosis palmaris, are inserted into the upper part of the second bone of each finger. Previous to this insertion, however, the fibres of each tendon decussate near the extremity of the first bone, so as to afford a passage to a tendon of the perforans. Of these four tendons, that of the middle finger is the largest, that of the fore-finger the next in size, and that of the little-finger the smallest. The use of this muscle is to bend the second joint of the fingers.

Fle'xor te'rtii interno'dii. See *Flexor longus pollicis manus.*

Flo'res be'nzoes. See *Benzoic acid.*

Flo'res martia'les. See *Ferrum ammoniatum.*

Flo'res sa'lis ammo'niaci. See *Ammoniæ subcarbonas.*

Flo'res sulphu'ris. See *Sulphur.*

Flo'res sulphu'ris lo'ti. See *Sulphur lotum.*

Flowers. A term formerly applied by chemists to the fine parts which are sublimated from certain bodies, as the flowers of benjamin, sulphur, zinc, &c.

Flower-de-luce. See *Iris germanica.*

Flowers of Benjamin. See *Benzoic acid.*

FLOYER, Sir John, was born at Hinters, in Staffordshire, about the year 1649, and graduated at Oxford. He then settled at Litchfield, where his attention and skill procured him extensive reputation, insomuch that he was honoured with knighthood, as a reward for his talents. He strongly advocated the use of cold bathing, particularly in chronic rheumatism, and nervous disorders: and he ascribed the increasing prevalence of consumption to the discontinuance of the practice of baptizing children by immersion. He published several works on this and other subjects; particularly an excellent treatise on the Asthma, under which he himself laboured from the time of puberty, notwithstanding which he lived to be an old man. He is said to have been one of the first, who reckoned the number of pulsations by a time-piece.

FLUATE. A salt formed by the fluoric acid, combined with different bases: thus, fluate of lime, &c.

FLUCTUA'TION. A term used by surgeons, to express the undulation of a fluid; thus, when pus is formed in an abscess, or when water accumulates in the abdomen, if the abscess or abdomen be lightly pressed with the fingers, the motion of fluctuation may be distinctly felt.

Fluellin. See *Antirrhinum elatine.*

FLUID. A fluid is that, the constituent particles of which so little attract each other, that, when poured out, it drops *guttatim*, and adapts itself, in every respect, to the form of the vessel containing it.

Fluids of the body. This term is often applied to the blood, and other humours of which the body is composed. The drying of any part of the human body demonstrates, that by far the greater part consists of fluid. The quantity of fluid in a man of one hundred and sixty pounds weight, is estimated at one hundred and thirty-five pounds. The fluids of the human body are divided into, 1. *Crude*, or those which have not yet entirely put on the animal nature, as the chyme and chyle. 2. *Sanguineous;* to this is referred the blood, or the cruor of the blood. 3. *Lymphatic*, which are those of the lymphatic vessels, and the nutritious jelly. 4. *Secreted;* to this head are referred all those separated from the blood, which are very numerous. 5. *Excrementitious*, which are eliminated from the body, as the alvine fæces, urine, cutaneous, and pulmonary perspirable matter, &c.

The secreted humours are divided into, 1. *Lacteal*, which are white; as the milk, juice of the prostate glands, &c. 2. *Aqueous*, as the aqueous humour of the eye. 3. *Mucous*, as the mucus of the nostrils and primæ viæ. 4. *Albuminous*, as the serum of the blood. 5. *Oleous*, as the oil of the adipose membrane. 6. *Bilious*, as the bile and wax of the ears.

The fluids of the human body are also divided from their motion into, 1. *Circulating*, which continually circulate in the vessels. 2. *Commorant*, which circulate with a slow motion as the oil of the adipose membrane and male semen. 3. *Stagnant*, which remain for a certain time in any receptacle, as cystic bile, urine, and the alvine fæces.

Flu'or a'lbus. See *Leucorrhœa.*

FLU'OR SPAR. Vitreous spar. Sparry fluor. Derbyshire spar. A species of salt which abounds in nature, formed by the combination of the fluoric acid with lime. It is called spar, because it has the sparry form and fracture: fluor, because it melts very readily; and vitreous, because it has the appearance of glass, and may be fused into glass of no contemptible appearance.

FLU'ORIC A'CID. The acidifiable base of fluoric acid is unknown; for no experiments have yet been made by which it can be exhibited. It is merely from general inference, that we may conjecture it to consist of a simple acidifiable basis united to oxygen.

This acid is to be obtained by putting one part of finely pulverised fluate of lime into a leaden retort, and pouring upon it two parts and a half of sulphuric acid. Lute the retort to a receiver of the same metal, and apply a gentle heat while the receiver is kept cool with a mixture of salt and snow. The fluoric acid will be obtained in the liquid form, which must be kept in well closed leaden or silver bottles, or phials coated within with wax, or varnish.

The distinguishing property of fluoric acid is, its power of dissolving and volatilizing silex. On being exposed to a moist atmospheric air, it emits white fumes which are very deleterious; and the liquid acts as a powerful corrosive. Its action upon all the inflammable substances is very feeble; it does not afford oxygen to them. It has no action upon most of the metals, but it dissolves many of their oxides.

Fluoric acid united to different bases, forms saline compounds called Fluates.

FLUO'RIC A'CID GAS. This is obtained when silex is added to the materials affording fluoric acid, or when vessels of glass are used; and it appears always to contain silex, whence it has been called silicated fluoric acid. It is heavier than atmospheric air. It does not maintain combustion, nor can animals breathe it. It is absorbed by water, depositing silex, and forms with it liquid fluoric acid. It has a penetrating odour, approaching nearly to that of muriatic acid gas. It corrodes animal and vegetable matters. Light has no effect upon it. It emits white fumes, in contact with moist atmospheric air. It is very sour, and therefore reddens blue vegetable colours. It precipitates lime-water. With ammonia it unites and forms a concrete body. It has no action upon platina, gold, silver, mercury, tin, lead, antimony, cobalt, nickel, and bismuth; but it attacks iron, arsenic, and manganese.

Flux. This word is mostly employed for *dysenteria.*

FLUXION. A term mostly applied by chemists, to signify the change of metals, or other bodies, from the solid into the fluid state, by the application of heat. See *Fusion.*

Fly, Spanish. See *Lytta.*

Fo'cile ma'jus. The ulna and the radius are occasionally denominated by the barbarous appellations of focile majus and minus; the tibia and fibula in the leg are also so called.

Fo'cus. A lobe of the liver.

Fodi'na. (From *fodio*, to dig.) A quarry. The labyrinth of the ear.

Fœnicula'tum li'gnum. A name for sassafras.

FŒNI'CULUM. (*Quasi fœnum oculorum*, the hay or herb good for the sight; so called because it is thought good for the eyes.) Fennel. See *Anethum.*

Fœni'culum alpi'num. The herb spignel.

Fœni'culum a'nnuum. Royal cummin.

Fœni'culum aqua'ticum. See *Phellandrium aquaticum.*

Fœni'culum du'lce. See *Anethum fœniculum.*

Fœni'culum germa'nicum. See *Anethum fœniculum.*

Fœni'culum mari'num. Samphire.

Fœni'culum orienta'le. Cuminum.

Fœni'culum porci'num. See *Peucedanum.*

Fœni'culum sine'nse. Aniseed.

Fœni'culum sylve'stre. Bastard spignel.

Fœni'culum tortuo'sum. French hartwort.

Fœni'culum vulga're. See *Anethum fœniculum.*

Fœ'num camelo'rum. See *Juncus odoratus.*

Fœ'num græ'cum. (*Fœnum*, hay, and *græcus*, belonging to Greece; because, in Greece, it grew in the meadows, like hay.) See *Trigonella fœnum græcum.*

Fœ'num sylve'stre. Wild fenugreek.

FOESIUS, Anutius, was born at Mentz, in 1528, and received his education at Paris, were he imbibed a strong predilection for the Greek language, and particularly the works of Hippocrates. Returning to his native place about the age of 28, his talents soon procured him such extensive reputation, that several princes endeavoured to allure him to their respective courts, but without success. The practice of his profession, instead of weakening his attachment to Hippocrates, only stimulated him to a more profound study of his writings; where he found the most correct delineations of diseases, and the most important observations concerning them, made about two thousand years before. He first published an excellent Latin translation and commentary on his second book of Epidemics; then an explanation of the terms used by him, under the title of "Œconomia Hippocratis;" and lastly, at the solicitation of the chief physicians of Europe, he undertook a complete correct edition of his works, with an interpretation and notes, which he accomplished in six years, in such a manner, as to rank him among the ablest interpreters of the antients. He was also author of a Pharmacopœia for his native city; and died in 1595.

Fœta'bulum. (From *fœteo*, to become putrid.) An encysted abscess, or foul ulcer.

FŒ'TUS. (From *feo*, to bring forth, according to Vossius.) *Epicyema. Epigonion.* The child enclosed in the uterus of its mother, is called a fœtus from the fifth month after pregnancy until the time of its birth. The internal parts peculiar to the fœtus, are the thymus gland, canalis venosus, canalis arteriosus, foramen ovale, and the membrana pupillaris. Besides these peculiarities, there are other circumstances in which the fœtus differs from the adult. The lungs are black and collapsed, and sink in water; the liver is very large; all the glands, especially the thymus and suprarenal, and the vermiform process of the cœcum, are also considerably larger in proportion. The teeth of the fœtus are hid within their sockets; the great intestines contain a substance called meconium; the membrana tympani is covered with a kind of mucous membrane, and the bones in many places are cartilaginous.

Folia'ta te'rra. (From its resemblance to *folium*, a leaf.) Sulphur, also the acetas potassæ.

Fo'lium orienta'le. See *Cassia senna.*

FO'LLICLE. (*Folliculus*; dim. of *follis*, a bag.) See *Folliculose gland.*

FOLLICULOSE GLAND. Follicle. One of the most simple species of gland, consisting merely of a hollow vascular membrane or follicle, and an excretory duct; such are the muciparous glands, the sebaceous, &c.

Folli'culus fe'llis. The gall-bladder.

FOMENTA'TION. *Fomentatio.* A sort of partial bathing, by applying hot flannels to any part, dipped in medicated decoctions, whereby steams are communicated to the diseased parts, their vessels are relaxed, and their morbid action sometimes removed.

Fo'mes ventri'culi. Hypochondriacism.

Fo'mites. A term mostly applied to substances imbued with contagion.

Fons pulsa'tilis. See *Fontanella.*

FONTANE'LLA. (Dim. of *fons*, a fountain.) *Fons pulsatilis.* The parietal bones and the frontal do not coalesce until the third year after birth, so that, before this period, there is an obvious interstice, commonly called *mould*, and scientifically the *fontanel*, or *fons pulsatilis.* There is also a lesser space, occasionally, between the occipital and parietal bones, termed the *posterior fontanel.* These spaces between the bones are filled up by the dura mater, pericranium and external integuments, so that during birth, the size of the head may be lessened; for, at that time, the bones of the head, upon the superior part, are not only pressed nearer to each other, but they frequently lap over one another, in order to diminish the size during the passage of the head through the pelvis.

Fontane'lla ante'rior. See *Fontanella.*

Fontane'lla poste'rior. See *Fontanella.*

FONTI'CULUS. (Dim. of *fons*, an issue.) An artificial ulcer formed in any part, and kept discharging by introducing daily a pea, covered with any digestive ointment.

FORA'MEN. (From *foro*, to pierce.) A little opening.

FORA'MEN CŒ'CUM. A single opening in the basis of the cranium between the ethmoid and the frontal bone, that gives exit to a small vein. Also the name of a a hole in the middle of the tongue.

FORA'MEN LA'CERUM IN BA'SI CRA'NII. See *Foramina lacera.*

FORA'MEN LA'CERUM ORBITA'LE SUPE'RIUS. A large opening between the greater and lesser wing of the sphenoid bone on each side, through which the third, fourth, first branch of the fifth, and the sixth pair of nerves, and the ophthalmic artery pass.

FORA'MEN O'PTICUM. The hole transmitting the optic nerve.

FORA'MEN OVA'LE. The opening between the two auricles of the heart of the fœtus. See also *Innominatum os.*

Fora'men of Winslow. An opening in the omentum. See *Omentum.*

FORA'MINA LA'CERA. A pair of foramina in the basis of the cranium, through which the internal jugular veins, and the eighth pair and accessary nerves pass.

Forami'nulum os. The ethmoid bone.

FO'RCEPS. (*-cipis*, f. *quasi ferriceps*, as being the iron with which we seize any thing hot, from *ferrum*, iron, and *capio*, to take.) Pincers. A surgical instrument with which extraneous bodies or other substances are extracted. Also an instrument occasionally used by men midwives to bring the head of the fœtus through the pelvis.

FORDYCE, George, was born at Aberdeen, in 1736, after the death of his father, and his mother having married again, he was sent to Fouran when about two years old, where he received his school education; and thence returned to Aberdeen, where he was made master of arts, when only fourteen. Having evinced an inclination to medicine, he was soon after sent to his uncle, Dr. John Fordyce, who practised at Uppingham, with whom he remained several years. He then studied at Edinburgh, where he graduated in 1758, having defended a thesis on catarrh: after which he went to Leyden, principally to improve himself in anatomy under Albinus. The following year he settled in London, and began to give lectures on chemistry; and in 1764, he undertook also to teach the practice of physic, and the materia medica: these subjects occupied him nearly three hours every morning, except on Sunday, for about thirty years successively. In 1770, he was chosen physician to St. Thomas's-hospital, and six years after a Fellow of the Royal Society: also in 1787 he was admitted a Fellow of the College of Physicians; having been a licentiate for twenty-two years before. In 1793 he assisted in forming a small society for the improvement of Medical and Chirurgical Knowledge, which has since published three volumes of their Transactions. He died in 1802. The countenance of Dr. Fordyce was by no means expressive of his powers of mind, he was rather negligent of his dress, and not sufficiently pleasing in his manners, to enable him to get into very extensive practice: besides he was too fond of the pleasures of society, to which he often sacrificed the hours, that should have been dedicated to sleep. The vigour of his constitution long resisted these irregularities; but at length they brought on the gout, which was followed by dropsy, and this terminated his existence. He possessed a remarkably strong memory, which enabled him to lecture without any notes, and to compose his works for publication without referring to authors, which he had before read: and his having relied too much on this faculty may help to explain the want of method and elegance, and the many inaccuracies, which appear in his writings. He was author of several publications on Medical and Philosophical subjects; many of which are to be found in the Transactions of the societies to which he belonged. The most esteemed, and that on which he employed most labour, was a series of "Dissertations on Fever;" four of them appeared during his life, and another was left in manuscript, which has since been printed. His Treatise on Digestion, was read originally as the Gulstonian Lecture before the College of Physicians. He was the projector of the Experiments in heated rooms, of which Sir Charles Blagden gave an account.

FORDYCE, Sir William, was born at Aberdeen in 1724. At the age of eighteen, having acquired a competent knowledge of physic and surgery, he went into the army; and the support of the friends, whom he there procured, together with his own merit, soon brought him into great practice, when he afterwards settled in London. The wealth, which he thus acquired, was liberally employed in acts of friendship, and in supporting useful projects; though he had some very severe losses. He wrote a Treatise on Fevers, and on the Ulcerated Sore Throat; on his entering into practice, he likewise published on the Venereal Disease. He died after a long illness in 1792.

FORESTUS, or Van Forest, Peter, was born at Alcmaer in 1522. He was sent to Louvain to study the law, but soon showed a strong inclination to medicine. He therefore cultivated this science at different universities in Italy, and afterwards at Paris; but he graduated at Bologna. After being twelve years settled in his native town, he was invited to Delft, which was ravaged by a contagious epidemic; and being extremely successful in the treatment of this, he received a considerable pension, and was retained as the public physician for nearly thirty years. In 1575 he was prevailed upon to give the first lecture on Medicine at the opening of the University of Leyden. He spent the latter part of his life in his native city, where he died in 1597. He was a very diligent observer of diseases, and shewed often great judgment in anticipating the result, or in treating them successfully. He published at different periods six volumes of Medical and Surgical Cases; to one of which was added a Dissertation, exposing the fallacy and absurdity of pretending to judge of every thing by the urine. Boerhaave has highly commended his writings which have been often reprinted.

Foreskin. See *Præputium.*

FO′RMIATE. *Formias.* A salt produced by the union of the formic acid with different bases: thus, *formiate of ammonia,* &c.

FORMI′CA. (*Quod ferat micas,* because of his diligence in collecting small particles of provision together.) 1. The ant or pismire. This industrious little insect, *Formica rufa* of Linnæus, contains an acid juice, and gross oil, which were supposed to possess aphrodisiac virtues. The chrysalides of this animal are said to be diuretic and carminative, and by some recommended in the cure of dropsy.

2. The name of a black wart with a broad base, and cleft superficies, because the pain attending it resembles the biting of an ant.

3. A varicose tumour on the anus and glans penis.

Formi′ca milia′ris. Any herpetic eruption.

FO′RMIC A′CID. *Acidum formicum.* The acid of ants was known to Tragus, Bauhin, Fisher, Etmuller, Hoffman, and many others. It is obtained chiefly from the red ant, *Formica rufa* of Linnæus, by distilling them in a retort, and by washing them in boiling water. When rectified and rather concentrated, it has a penetrating smell, and is corrosive; and its taste is so agreeable, when greatly diluted with water, that it has been proposed to be used instead of vinegar.

Fo′rmix. The herpes exedens.

FO′RMULA. (Dim. of *forma,* a form.) A little form of prescriptions, such as physicians direct in extemporaneous practice, in distinction from the greater forms in pharmacopœias, &c.

Fo′rnax. *Furnus.* A furnace. A chemical instrument. See *Furnace.*

FO′RNIX. (*Fornix,* an arch or vault.) A part of the corpus callosum in the brain is so called, because, if viewed in a particular direction, it has some resemblance to the arch of an ancient vault. It is the medullary body, composed of two anterior and two posterior crura, situated at the bottom and inside of the lateral ventricle over the third ventricle, and below the septum lucidum.

Fo′rtis a′qua. A weak nitric acid.

FO′SSA. (From *fodio,* to dig.) *Fovea.* A little depression or sinus. The pudendum muliebre.

Fo′ssa amy′ntæ. A double-headed roller for the face.

Fo′ssa ma′gna. The great groove of the ear, also the pudendum muliebre.

Fo′ssa navicula′ris. The cavity at the bottom of the entrance of the pudendum muliebre: also the great groove of the ear.

Fo'ssa ova'lis. The depression in the right auricle of the human heart, which in the fœtus opened into the other auricle, forming the foramen ovale.

Fo'ssa pituita'ria. The fossa of the sella turcica of the sphenoid bone.

FO'SSIL. (*Fossilis*, from *fodio*, to dig.) Any thing dug out of the earth.

Fo'ssilus. The bone of the leg.

FOTHERGILL, John, was born in Yorkshire, in 1712, of a respectable Quaker family. After passing through an apprenticeship to an apothecary, he went to Edinburgh, where he graduated at the age of twenty-four, taking for his inaugural thesis the use of emetics. He then studied for two years at St. Thomas's-hospital, and after an excursion to the continent, settled in London in 1740, and six years after became a licentiate. His practice was for some time chiefly gratuitous; but his "Account of the Putrid Sore Throat," published in 1748, brought him speedily into reputation. He was successively elected a Fellow of the College of Physicians at Edinburgh, of the Royal Society of London, and of some other societies abroad. His early partiality to botany induced him, as his practice increased, to purchase a large piece of ground for the cultivation of rare and valuable plants, in which he spared no expence; neither did he neglect other departments of natural history. He was also an active and liberal promoter of many successful schemes for the public benefit; and particularly in instituting the school at Ackworth in Yorkshire. He was of a rather delicate constitution, but a steady temperance preserved his health, till in 1778 he had an attack of a suppression of urine, occasioned by a disease of the prostate gland; which returning two years after, soon put a period to his existence. He had a quick and comprehensive understanding; and his pleasing address procured him general confidence, which his discretion was not apt to forfeit afterwards. Besides the works already noticed, several papers of Dr. Fothergill were printed in the Philosophical Transactions, and in the Medical Observations and Enquiries: he also sent several communications to the Gentleman's Magazine, and other periodical publications.

Fo'tus. (*Fotus, us*, m.) See *Fomentation.*

FO'VEA. (From *fodio*, to dig.) A little depression. The pudendum muliebre. A partial sweating-bath.

Fox-glove. See *Digitalis.*

Fox-glove, Eastern. See *Sesamum orientale.*

FRACASTORIUS, Hieronymus, was born at Verona in 1483. He made a rapid progress in his studies, and attained early considerable excellence as a poet, philosopher, and astronomer. He was also much valued as a physician, particularly by the general of the Venetian army, whom he attended during several campaigns: but on his dying in 1515, Fracastorius returned to his native place. He corresponded with most of the great men of his age, especially with Cardinal Bembo, to whom he dedicated his poem "Syphilis;" which was thought worthy of comparison with the Georgics of Virgil by some of the best judges. He died in 1553; and a statue was erected to him by the town of Verona. He published also on Contagious Diseases, and several other Medical and Philosophical Subjects.

FRA'CTURE. (*Fractura*; from *frango*, to break.) *Catagma. Clasis. Clasma. Agme.* A fracture is a solution of a bone into two or more fragments. A *simple* fracture is when the bone only is divided. A *compound* fracture is a division of the bone, with a laceration of the integuments, the bone mostly protruding. A fracture is also termed transverse, oblique, &c. according to its direction.

FRÆ'NULUM. (Dim. of *frænum*, a bridle.) The cutaneous fold, under the apex of the tongue, that connects the tongue to the infralingual cavity. It is sometimes, in infancy, so short as to prevent the child from sucking, when it is necessary to cut it, in order to give more room for the motion of the tongue.

FRÆ'NUM. The membranous fold which connects the prepuce to the inferior part of the glans penis.

Fra'ga. (From *fragro*, to smell sweet.) The strawberry. See *Fragaria.*

FRAGARIA. (From *fragro*, to smell sweet.) The strawberry.

1. The name of a genus of plants in the Linnæan system. Class, *Icosandria.* Order, *Polygynia.*

2. The pharmacopœial name of the strawberry. See *Fragaria vesca.*

Fra'garia ste'rilis. Barren strawberry. Astringent.

Fra'garia vesca. The systematic name of the strawberry. *Fragaria. Fraga.* The mature fruit of the *Fragaria vesca, fragellis reptantibus* of Linnæus, was formerly recommended in gouty and calculous affections, in consequence, it would appear, of its efficacy in removing tartar from the teeth, which it is said to do very effectually.

Fragi'litas o'ssium. *Friabilitas ossium.* Brittleness of the bones.

Fra'gmen. *Fragmentum.* A splinter of a bone.

FRAMBŒ'SIA. (From *framboise*, Fr. for a raspberry.) The yaws. A genus of disease arranged by Cullen in the class *cachexiæ*, and order *impetigines.* It is somewhat similar in its nature to the lues venerea, and is endemial to the Antilles islands, as well as Africa. It appears with excrescences like mulberries growing out of the skin in various parts of the body, which discharge an ichorous fluid.

FRA'NGULA. (From *frango*, to break, so called because of the brittleness of its branches.) See *Rhamnus frangula.*

Frankincense. See *Juniperus Lycia*, and *Pinus abies.*

Fraxine'lla. (From *fraxinus*, the ash, so called because its leaves resemble those of the ash.) See *Dictamnus albus.*

Fraxinella, white. See *Dictamnus albus.*

FRA'XINUS. (*A fragore*, from the noise its seeds make when shaken by the wind; or from φραξις, a hedge, because of its use in forming hedges.) The ash.

1. The name of a genus of plants in the Linnæan system. Class, *Polygamia.* Order, *Dioecia.* The ash.

2. The pharmacopœial name of the ash-tree. See *Fraxinus excelsior.*

Fra'xinus exce'lsior. The systematic name of the ash-tree. *Fraxinus.* Called also *brumelli* and *bumelia.* The bark of this tree, *Fraxinus excelsior; foliis serratis floribus apetalis*, of Linnæus, when fresh, has a moderately strong bitterish taste. It possesses resolvent and diuretic qualities, and has been successfully exhibited in the cure of intermittents. The seeds, are occasionally exhibited medicinally as diuretics, in the dose of a drachm. In warm climates, a sort of manna exudes from this species of fraxinus.

Fra'xinus o'rnus. The systematic name of the tree from which manna flows. This substance is also termed *Manna calabrina. Ros calabrinus. Acromeli. Alusar. Drysomeli.* That species which is of a rosy colour, is called *nuba. Mel aerium*, from the supposition that it descended from heaven. The condensed juice of the flowering ash, or *Fraxinus ornus: foliis ovato-oblongis serratis petiolatis, floribus corollatis.* Hort. Kew. which is a native of the southern parts of Europe, particularly Sicily and Calabria. Many other trees and shrubs have likewise been observed to emit a sweet juice, which concretes upon exposure to the air, and may be considered of the manna kind, especially the *Fraxinus rotundifolia* and *excelsior.* In Sicily, these three species of fraxinus are regularly cultivated for the purpose of procuring manna, and with this view are planted on the declivity of a hill with an eastern aspect. After ten years growth, the trees first begin to yield the manna, but they require to be much older before they afford it in any considerable quantity. Although the manna exudes spontaneously upon the trees, yet, in order to obtain it more copiously, incisions are made through the bark, by means of a sharp crooked instrument; and the season thought to be most favourable for instituting this process, is a little before the dog-days commence, when the weather is dry and serene. Manna is generally distinguished into different kinds, viz. the manna in tear, the canulated and flaky manna, and the common brown or fat manna. All these varieties seem rather to depend upon their respective purity, and the manner in which they are obtained from the plant, than upon any essential difference of the drug. The best manna is in oblong pieces, or flakes, moderately dry, friable, very light, of a whitish, or pale yellow colour, and in some degree transparent: the inferior kinds are moist, unctuous and brown. Manna is well known as a gentle purgative, so mild in its operation, that it may be given with safety to children and pregnant women, to the delicacy of whose frames and situations it is particularly adapted. It is esteemed a good and pleasant auxiliary to the purgative neutral salts. It sheathes acrimony, and is useful in coughs, disorders of the breast, and such as are attended with fever and inflammation, as in pleuritis, &c. It is particularly efficacious in bilious complaints, and helps the discharge of mineral waters, when they are not of themselves sufficiently active. It is apt in large doses to create flatulencies and gripes; both of which are prevented by a small addition of some warm carminatives. It purges in doses of from ℥j to ℥jj; but its purgative quality is much increased, and its flatulent effects prevented, by a small addition of cassia. The dose for children is from one scruple to three. It is best dissolved in whey.

Fra'xinus rotundifo'lia. The systematic name of a tree which affords manna. See *Fraxinus ornus.*

FREIND, John, was born in 1675 at Croton in Northamptonshire, of which his father was rector. After being educated at Westminster he went to Oxford, where he distinguished himself greatly by his classical attainments. Having for some time studied medicine, he communicated to the Royal Society some singular cases: but a work, which he published in 1703, entitled "Emmenologia," explaining the phœnomena of menstruation both natural and morbid, on mechanical principles, first brought him into notice as a physiologist and physician. In the following year he was appointed professor of Chemistry at Oxford, but soon after went to Spain as physician to the English forces; and he took this opportunity of visiting Italy. On his return in 1707, he was created Doctor by diploma, and published his Chemical Lectures in Latin. In 1712 he was chosen a Fellow of the Royal Society; but soon went abroad again with the troops into Flanders. On the conclusion of the peace in the following year he settled in London, and rose to high professional reputation. In 1716 he was received as Fellow of the College of Physicians, and published the first and third books of Hippocrates on Epidemics, with a Commentary on Fevers, in nine parts; a work of great erudition and judgment. Some of his opinions having been severely attacked, he was led to defend them in a letter to Dr. Mead, entitled "De Purgantibus in secundo Variolarum confluentium Febre adhibendis," 1719. A few years after this he got into Parliament, and having warmly sided with the opposition, he was, in common with several persons of consequence, imprisoned on suspicion of high treason: but the minister, Sir Robert Walpole, having fallen sick, Dr. Mead refused to attend him till his friend was liberated; when he made over to him 5000 guineas, which he had received from his patients during his confinement of a few months only. While in the tower, Dr. Freind formed the plan of his great work "The History of Physic from Galen to the beginning of the Sixteenth Century, chiefly with regard to Practice;" which came out in two volumes within three years after. This was intended as a continuation of Le Clerc, and met with a very favourable reception; indeed it still continues to be a standard book. On the accession of George II. he was appointed physician to the Queen; and having died in July 1728, his widow and son experienced the royal protection.

Fre'na. The sockets of the teeth.

Frigida'rium. (From *frigidus*, cold.) The cold bath.

Frigera'na. A putrid fever.

FRONS. (*Frons*, *-tis*, f. or m.) The forehead. The part between the eyebrows and the hairy scalp.

Frontal bone. } See *Frontis os.*
Frontal sinus. }

Fronta'lis. See *Occipitio frontalis.*

Fronta'lis ve'rus. See *Corrugator supercilii.*

FRO'NTIS OS. The frontal bone. *Os coronale. Os inverecundum. Metopon.* The external surface of this bone is smooth at its upper convex part, but below several cavities and processes are observed. At each angle of the orbits the bone jets out to form two internal and two external processes; and the ridge under the eyebrow on each side is called the superciliary process; from which the orbitar processes extend backwards, forming the upper part of the orbits; and between these the ethmoid bone is received. The nasal process is situated between the two internal angular processes. At the internal angular process is a cavity for the caruncula lachrymalis; and at the external, another for the pulley of the major oblique muscle. The foramina are three on each side; one in each superciliary ridge, through which a nerve, artery, and vein, pass to the integuments of the forehead; a second near the middle of the internal side of the orbit, called internal orbitar; the third is smaller and lies about an inch deeper in the orbit. On the inside of the os frontis there is a ridge which is hardly perceptible at the upper part, but grows more prominent at the bottom, where the foramen cæcum appears; to this ridge the falx is attached. The frontal sinus is placed over the orbit on each side, except at this part the frontal bone is of mean thickness between the parietal and occipital: but the orbitar process is so thin as to be almost transparent.

Fru'ctus horæ'i. See *Fruits, summer.*

FRUITS, SUMMER. *Fructus horæi.* Under this term physicians comprehend strawberries, cherries, currants, mulberries, raspberries, and the like. They possess a sweet sub-acid taste, and are exhibited as dietetic auxiliaries, as refrigerants, antiseptics, attenuants, and aperients. Formerly they were exhibited medicinally in the cure of putrid affections, and to promote the alvine and urinary excretions. Considering them as an article of diet, they afford little nourishment, and are liable to produce flatulencies. To persons of a bilious constitution and rigid fibres, and where the habit is disposed naturally, or from extrinsic causes, to an inflammatory or putrescent state, their moderate, and even plentiful use, is salubrious; by those of a cold inactive disposition, where the vessels are lax, the circulation languid, and the digestion weak, they should be used very sparingly. The juices extracted from these fruits by expression, contain their active qualities freed from their grosser indigestible matter. On standing, the juice ferments and changes to a vinous or acetous state. By proper addition of sugar, and by boiling, their fermentative power is suppressed, and their medicinal qualities preserved. The juices of these fruits, when purified from their fæculencies by settling and straining, may be made into syrups, with a due proportion of sugar in the usual way.

FRUMENTA'CEOUS. A term applied to all such plants as have a conformity with wheat, either with respect to their fruit, leaves, or ears.

FU'CUS. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia.* Order, *Algæ.*

Fu'cus digita'tus. This fucus grows upon stones and rocks in the sea near the shore. It has several plain, long leaves or sinuses springing from a round stalk, in the manner of fingers when extended. It affords soda.

Fu'cus escule'ntus. Edible fucus. Mr. Hudson has made this a distinct species, but Linnæus included it under his saccharinus. It grows plentifully in the sea near the shores of Scotland, and also those of Cumberland. It has a broad, plain, simple, sword-shaped leaf, springing from a pinnated stalk.

Fu′cus helminthoco′rton. See *Corallina corsicana.*

Fu′cus palma′tus. Handed fucus. This grows in the sea and consists of a thin lobed leaf like a hand.

Fu′cus sacchari′nus. Sea-belts; so called from the supposed resemblance of its leaves to a belt or girdle. It grows upon rocks and stones by the sea-shore The leaves are very sweet, and when washed and hung up to dry, will exude a substance like sugar, from whence it was named.

Fu′cus vesiculo′sus. The systematic name of the sea oak. *Quercus marina.* The sea oak. Sea wreck. This sea-weed is the *Fucus vesiculosus fronde plana dichotoma costata integerrima, vesiculis axillaribus geminis, terminalibus tuberculatis,* of Linnæus. It is said to be a useful assistant to sea-water, in the cure of disorders of the glands. Burnt in the open air, and reduced to a black powder, it forms the æthiops vegetabilis, which, as an internal medicine, is similar to burnt sponge.

FULI′GO. (*Quasi fumiligo,* from *fumus,* smoke.) *Araxos. Asoper. Asuoli.* Soot. Wood soot, *fuligo ligni,* or the condensed smoke from burning wood, has a pungent, bitter, and nauseous taste, and is resolved by chemical analysis into a volatile alkaline salt, an empyreumatic oil, a fixed alkali, and an insipid earth. The tincture prepared from this substance, *tinctura fuliginis,* is recommended as a powerful antispasmodic in hysterical affections.

FULMINA′TION. A quick and lively explosion of bodies, such as takes place with fulminating gold, fulminating powder, and in the combustion of a mixture of inflammable gas and vital air.

FUMA′RIA. (From *fumus,* smoke, from its juice when dropped into the eye, producing the same sensations as smoke.)

1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia.* Order, *Decandria.* Fumitory.

2. The pharmacopœial name of the common fumitory. See *Fumaria officinalis.*

Fuma′ria bulbo′sa. *Aristolochia fabacea.* The root of this plant, *Fumaria bulbosa caule simplici, bracteis longitudine florum,* of Linnæus, was formerly given to restore suppressed menses, and as an anthelmintic.

Fuma′ria officina′lis. The systematic name of the fumitory. *Fumaria. Fumus terræ. Capnos. Herba melancholifuga.* The leaves of this indigenous plant, *Fumaria officinalis pericarpiis monospermis racemosis, caule diffuso,* of Linnæus, are directed for medicinal use by the Edinburgh college; they are extremely succulent, and have no remarkable smell, but a bitter, somewhat saline taste. The infusion of the dried leaves, or the expressed juice of the fresh plant, is esteemed for its property of clearing the skin of many disorders of the leprous kind.

FUMIGA′TION. The application of fumes, either from metallic or other preparations to particular parts of the body, as those of the mercurial kind to venereal sores, &c.

Fumitory. See *Fumaria.*

Fu′mus a′lbus. Mercury.

Fu′mus ci′trinus. Sulphur.

Fu′mus du′plex. Sulphur and mercury.

Fu′mus ru′bens. Orpiment.

FUNCTION. See *Action.*

FU′NGUS. 1. Proud flesh. A term in surgery to express any luxuriant formation of flesh.

2. The name of an order of plants in the Linnæan system, belonging to the *Cryptogamia* class.

Fu′ngus ignia′rius. See *Boletus igniarius.*

Fu′ngus la′ricis. See *Boletus laricis.*

Fu′ngus melite′nsis. This is improperly called a fungus. See *Cynomorium.*

Fu′ngus rosa′ceus. See *Bedeguar.*

Fu′ngus sa′licis. The willow fungus. See *Boletus suaveolens.*

Fu′ngus sambu′cinus. See *Peziza Auricula.*

Fu′ngus vino′sus. The dark cobweb-like fungus, which vegetates in dry cellars, where wine, ale, and the like are kept.

FUNI′CULUS UMBILICA′LIS. (*Funiculus;* dim. of *funis,* a cord.) See *Umbilical cord.*

Fu′nis. A rope or cord.

FU′NIS UMBILICA′LIS. See *Umbilical cord.*

Furce′lla infe′rior. The ensiform cartilage.

Fu′rcula. The clavicle.

FU′RFUR. Bran. A disease of the skin, in which the cuticle keeps falling off in small scales like bran.

FURFURA′CEOUS. (*Furfuraceus,* from *furfur,* bran.) A term applied to the sediment deposited in the urine of persons afflicted with fever, of a reddish or whitish matter, which generally appears within an hour or two after the urine is passed, and only falls in part to the bottom, the urine remaining turbid.

FURNACE. *Furnus.* The furnaces employed in chemical operations are of three kinds: 1. The *evaporatory furnace,* which has received its name from its use; it is employed to reduce substances into vapour by means of heat, in order to separate the more fixed principles from those which are more volatile. 2. The *reverberatory furnace,* which name it has received from its construction, the flame being prevented from rising; it is appropriated to distillation. 3. The *forge furnace,* in which the current of air is determined by bellows.

Fu′ror uteri′nus. (From *furo,* to be mad, and *uterus,* the womb.) See *Nymphomania.*

FURU′NCULUS. (From *furo,* to rage;

so named from its heat and inflammation before it suppurates.) *Dothein* of Paracelsus. *Chiadus. Chioli.* A boil. An inflammation of a subcutaneous gland, known by an inflammatory tumour that does not exceed the size of a pigeon's egg.

FUSION. (*Fusio; from fundo*, to pour out.) A chemical process, by which bodies are made to pass from the solid to the fluid state, in consequence of the application of heat. The chief objects susceptible of this operation are salts, sulphur, and metals. Salts are liable to two kinds of fusion: the one, which is peculiar to saline matters, is owing to water contained in them, and is called *aqueous fusion;* the other, which arises from the heat alone, is known by the name of *igneous fusion.*

G.

GABIA′NUM O′LEUM. See *Petroleum rubrum.*

GABI′REA. A fatty kind of myrrh, mentioned by Dioscorides.

GALA′CTIA. (From γαλα, milk.) *Galactirrhœa.* An excess or overflowing of the milk.

GALA′CTINA. (From γαλα, milk.) Aliment prepared of milk.

GALACTIRRHŒ′A. (From γαλα, milk, and ρεω, to flow.) See *Galactia.*

GALACTO′DES. (From γαλα, milk.) In Hippocrates it signifies both milk warm and a milky colour.

GALACTO′PHORA MEDICAME′NTA. (From γαλα, milk, and φερω, to bring.) Medicines which increase the milk.

GALACTO′PHOROUS DUCTS. (*Galactophorus;* from γαλα, milk, and φερω, to carry, because they bring the milk to the nipple.) The excretory ducts of the glands of the breasts of women, which terminate in the papilla, or nipple, are so called.

GALACTOPOE′TICA. (From γαλα, milk, and ποιεω, to make.) Milk-making, an epithet applied to the faculty of making milk.

GALACTOPO′SIA. (From γαλα, milk, and πινω, to drink.) The method of curing diseases by a milk diet.

GALA′NGA. (Perhaps its Indian name.) See *Maranta* and *Kæmpferia.*

GALA′NGA MA′JOR. See *Kæmpferia Galanga.*

GALA′NGA MI′NOR. See *Maranta Galanga.*

Galangal. See *Galanga.*

Galangal, English. See *Cyperus.*

GALBANUM. (From *chalbanah*, Heb.) See *Bubon galbanum.*

GA′LBEI. *Galbeum.* A sort of ornamental and medical bracelets worn by the Romans.

GA′LBULUS. (From *galbus*, yellow.) When the skin of the body is naturally yellow.

GA′LDA GU′MMI. This is a gum-resin, mentioned by old writers, but totally forgot in the present day, and not to be obtained. Externally, it is of a brown colour, but white within, of a hard lamellated structure, and smells and tastes somewhat like elemi. When burnt it gives out an agreeable odour. It was formerly used as a warm, stimulating medicine, and applied in plasters as a strengthener.

GA′LEA. (From γαλη, a cat, of the skin of which it was formerly made.) A helmet. In anatomy, the amnios is so called, because it surrounds the fœtus like a helmet. In surgery, it is a bandage for the head. A species of head-ach is so called, when it surrounds the head like a helmet.

GALEANTHRO′PIA. (This term seems to be from γαλη, a cat, and ανθρωπος, a man.) It is a species of madness, in which a person imagines himself to be a cat, and imitates its manners.

GA′LEGA. (From γαλα, milk; so named because it increases the milk of animals which eat it.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia.* Order, *Decandria.*

2. The pharmacopœial name of the *Ruta capraria.* See *Galega officinalis:*

GA′LEGA OFFICINA′LIS. The systematic name of the goats rue. *Galega. Ruta capraria.* Goats rue. From the little smell and taste of this plant, *Galega officinalis; leguminibus strictis, erectis; foliolis lanceolatis, striatis, nudis,* of Linnæus, it may be supposed to possess little virtues. In Italy, the leaves are eaten amongst salads.

GA′LEGÆ. A species of senna. The *cassia tora* of Linnæus.

GALENUS, CLAUDIUS, was born at Pergamus, in Asia Minor, in 131. His father, Nicon, having instructed him in the rudiments of knowledge, sent him to attend the best schools of philosophy. Galen soon displayed his judgment by selecting what appeared most rational from the different sects; but he totally rejected the Epicurean system, which was then in fashion. About the age of 17, he began his attachment to the science of medicine, over which he was destined to preside for many centuries with oracular authority. During his youth, he travelled much, that he might converse with the most intelligent physicians of the age, and inform himself concerning the drugs brought from other countries. He resided several years at Alexandria, which was then the great resort of men of science, and the best school of medicine in the world. At the age of 28, returning to his native place, he met with distinguished success in practice; but four years after he attempted to establish himself at Rome. Here he encountered much opposition from his professional brethren, who stigmatized him as a theorist, and even as a dealer in magic; and though he gained the esteem of several men of learning and rank, yet wanting temper and experience, sufficient to maintain a successful contest with a numerous and popular party, he was obliged to return to Pergamus within five years, under the pretence of avoiding the plague, which then raged at Rome. He was however soon after sent for to attend the Emperors Marcus Aurelius and Lucius Verus, of whom the latter died; and the former conceived so high an opinion of Galen, that subsequently during his German expedition, he committed his two sons to the care of that physician. These princes were seized with fevers, in which Galen having prognosticated a favourable issue, contrary to the opinion of all his colleagues, and having accordingly restored them to health, he attained an eminence of reputation, which enabled him to defy the power, and finally to ruin the credit, of his former opponents. It is not certain, whether he continued at Rome till his death, nor at what precise period this occurred; but Fabricius asserts that he attained the age of 70, which corresponds to the 7th year of Severus; and his writings appear to indicate, that he was still in that city in the early part of this emperor's reign. The greatest part of Galen's life was spent in the zealous pursuit of knowledge, and especially of every thing which might have the least connection with medicine; and he is said to have composed about 750 different essays on such subjects. He appears however to have been too much elated with the consciousness of his superior endowments, and to have behaved rather contemptuously towards his brethren; which may have inflamed their opposition to him. The chief object in his writings appears to be to illustrate those of Hippocrates, which he thought succeeding physicians had misunderstood or misrepresented: in this he has displayed great acuteness and learning, though he has not much increased the stock of practical information. His example too had the unfortunate effect of introducing a taste for minute distinctions and abstract speculations; while the diligent observation of nature, which distinguished the father of medicine, fell into neglect. We must therefore regret, that the splendour of Galen's talents so completely dazzled his successors, that, until about the middle of the 17th century, his opinions bore an almost undivided sway. Numerous editions of his works, in the original Greek, or translated into Latin, have been printed in modern times.

GALE′NA. (From γαλειν, to shine.) The name of an ore formed by the combination of lead with sulphur.

Gale′nic me′dicine. That practice of medicine which conforms to the rules of Galen, and runs much upon multiplying herbs and roots in the same composition, though seldom torturing them any otherwise than by decoction. It is opposed to chemical medicine, which, by the force of fire, and a great deal of art, fetches out the virtues of bodies, chiefly mineral, into a small compass.

Gale′nium. (From γαληνη, galena.) A cataplasm; in the composition of which was the galena. In Paulus Ægineta it is considered as anodyne.

Galeo′bdolon. (From γαλεη, *felis*, and βδολος, *crepitus*.) See *Galeopsis*.

Galeo′psis. (From καλος, good, and οψις, vision; so called because it was thought good for the sight; or from γαλη, a cat, and οψις, aspect; the flowers gaping like the open mouth of that animal.) *Galeobdolon. Lamium rubrum. Urtica iners magna fœtidissima. Stachys fœtida.* Hedge nettle. See *Lamium album*.

Galeri′culum aponeuro′ticum. The tendinous expansion which lies over the pericranium.

GA′LIUM. (From γαλα, milk; some species having the property of coagulating milk.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*. Order, *Monogynia*.

2. The pharmacopœial name of the herb cheese rennet, or ladies bedstraw. See *Galium verum*.

3. A name for madder.

Ga′lium a′lbum. The greater ladies bedstraw. See *Galium mollugo*.

Ga′lium apari′ne. The systematic name of the goose-grass. *Aparine. Philanthropus. Ampelocarpus. Omphalocarpus. Ixus. Asparine. Asperula.* Goose-grass and cleaver's bees. Cleavers. Goose-share. Hayriff. This plant, which is common in our hedges and ditches, is the *Galium aparine, foliis octonis lanceolatis carinatis scabris retrorsum aculeatis, geniculis venosis, fructu hispido*, of Linnæus. The expressed juice has been given with advantage as an aperient and diuretic in incipient dropsies; but the character in which it has of late been chiefly noticed, is that of a remedy against cancer. A tea-cup full, internally, gradually increased to half a pint, two or three times a day, and the herb applied, in cataplasm, externally, has been said to cure cancers. Such beneficial results are not confirmed by the experience of others.

Ga'lium mollu'go. The systematic name of the greater ladies bedstraw. *Galium album.* This herb, *Galium; foliis octonis, ovato-linearibus, subserratis, patentissimis, mucronatis; caule flaccido, ramis patentibus,* with its flowers, are used medicinally. Five ounces, or more, of the expressed juice, taken every evening upon an empty stomach, is said to cure epilepsy.

Ga'lium ve'rum. The systematic name of the true ladies bedstraw, or cheese-rennet. *Galium.* The tops of this plant, *Galium verum; foliis octonis, linearibus, sulcatis; ramis floriferis, brevibus,* of Linnæus, were long used as an efficacious medicine in the cure of epilepsy, but, in the practice of the present day, they are abandoned. Indeed, from the sensible qualities of the plant, little can be expected. The leaves and flowers possess the property of curdling milk; it is on that account styled cheese-rennet.

Gall. See *Bile.*

GALL SICKNESS. A popular name for the remitting fever occasioned by marsh miasmata, in the Netherlands, and which proved so fatal to thousands of the English soldiers after the capture of Walcheren in the year 1809. Dr. Lind informs us, that at Middleburgh, the capital of Walcheren, a sickness generally reigns towards the latter end of August or the beginning of September, which is always most violent after hot summers. It commences after the rains which fall in the end of July; the sooner it begins the longer it continues, and it is only checked by the coldness of the weather. Towards the end of August and the beginning of September, it is a continual burning fever, attended with a vomiting of bile, which is the *gall sickness.* This fever, after continuing three or four days, intermits, and assumes the form of a double tertian; leaving the patient in a fortnight, or perhaps sooner. Strangers, that have been accustomed to breathe a dry, pure air, do not recover so quickly. Foreigners in indigent circumstances, such as the Scots and German soldiers, who were garrisoned in the adjacent places, were apt, after those fevers, to have a swelling in the legs, and a dropsy; of which many died.

These diseases are the same with the double tertians common within the tropics. Such as are seized with the gall sickness, have at first some flushes of heat over the body, a loss of appetite, a white, foul tongue, a yellow tinge in the eyes, and a pale colour of the lips. Such as live well, drink wine, and have warm clothes, and a good lodging, do not suffer so much during the sickly season as the poor people; however, these diseases are not infectious, and seldom prove mortal to the natives.

Sir John Pringle observes, that the prevailing epidemic of autumn, in all marshy countries, is a fever of an intermitting nature, commonly of a tertian form, but of a bad kind; which, in the dampest places and worst seasons, appears as a double tertian, a remitting, or even an ardent fever. But, however these may vary in their appearance, according to the constitution of the patient and other circumstances, they are all of a similar nature. For though, in the beginning of the epidemic, when the heat, or rather the putrefaction in the air, is the greatest, they assume a continued or a remitting form; yet, by the end of autumn, they usually terminate in regular intermittents.

But although, in the gall sickness, there is both a redundance and a depravation of the bile, still the disease cannot, with justice, be said to originate wholly from that cause. It is certain, however, that the disease may be continued, and the symptoms aggravated, by an increased secretion and putrefaction of the bile, occasioned by the fever. In proportion to the coolness of the season, or the height and dryness of the ground, this disease is milder, remits and intermits more freely, and removes further from the nature of a continued fever. The higher ranks of people in general are the least liable to the diseases of the marshes; for such countries require dry houses, apartments raised above the ground, moderate exercise, without labour, in the sun, or evening damps; a just quantity of fermented liquors, plenty of vegetables and fresh meats. Without such helps, not only strangers but the natives themselves are sickly, especially after hot and close summers. The hardiest constitutions are very little excepted more than others; and hence the British in the Netherlands have always been subject to fevers.

By this disease, the British troops were harrassed throughout the war, from 1743 to 1747. It appeared in the month of August, 1743: the paroxysms came on in the evening, with great heat, thirst, a violent headach, and often a delirium. These symptoms lasted most of the night, but abated in the morning, with an imperfect sweat; sometimes with an hæmorrhage of the nose, or looseness. The stomach, from the beginning, was disordered with a nausea and sense of oppression; frequently with a bilious and offensive vomiting. If evacuations were either neglected or too sparingly used, the patient fell into a continued fever, and sometimes grew yellow, as in jaundice. When the season was further advanced, this fever was attended with a cough, rheumatic pains, and sizy blood. The officers, being better accommodated than the common men, and the cavalry, who had cloaks to keep them warm, were not so subject to it; and others who belonged to the army, but lay in quarters, were least of all affected;

and the less in proportion to their being exposed to heats, night damps, and the other fatigues of the service. In this manner did the remitting fever infest the army for the remaining years of the war: and that exactly in proportion to their distance from the marshy places, of which we have several notable instances in Pringle's observations.

GA'LLA. (From *Gallus*, a river in Bithynia.) See *Quercus cerris.*

GA'LLA TU'RCICA. See *Quercus cerris.*

GALL-BLADDER. *Vesicula fellis.* An oblong membranous receptacle, situated under the liver, to which it is attached in the right hypochondrium. It is composed of three membranes: a common, fibrous, and villous. Its use is to retain the bile which regurgitates from the hepatic duct, there to become thicker, more acrid, and bitter, and to send it through the cystic duct, which proceeds from its neck into the ductus communis choledochus, to be sent on to the duodenum.

GALL-STONES. Biliary concretions. Hard concrete bodies, of which there are great varieties, formed in the gall-bladder of animal bodies. Gall-stones often lie quiet; so that, until dissection after death, some are never known to exist; but when they are prevented from passing through the gall ducts, they obstruct the passage of the bile into the intestines, and produce also many inconvenient symptoms, particularly the jaundice.

The diagnostics of this disorder are generally very obscure and uncertain: for other causes produce the same kind of symptoms as those which occur in this disease. The usual symptoms are a loss of appetite, a sense of fulness in the stomach, sickness and vomiting, languor, inactivity, sleepiness; and, if the obstruction continues for a time, there is wasting of the flesh; yellowness of the eyes, skin, and urine; whitish stools; a pain in the pit of the stomach; whilst the pulse remains in its natural state. The pain excited by an obstruction of the gall ducts, in consequence of gall-stones passing through them, and this not affecting the pulse, is considered as the leading pathognomonic symptom. This pain, in some, is extremely acute, in others there is only a slight uneasiness felt about the region of the liver; but its particular seat is the gall duct, just where it enters the duodenum. In some patients there is no yellowness of the skin; in others it exists for several months. There is no disease more painful than this, in some instances; it is as frequent as any other affection of the liver; it admits of much relief from medicine, and is not immediately dangerous to the patient. See *Icterus.*

GA'LLIC ACID. A peculiar acid which is extracted from the nut-gall that grows on the oak. This acid is also found, in a greater or less quantity, in all astringent vegetable substances.

GALLI'TRICHIS. Corrupted from *callitrichis*, or *callitrichum.*

GA'LLICUS MO'RBUS. The French disease. See *Lues venerea.*

GALLINA'GO. (Diminutive of *gallus*, a cock.) 1. The woodcock.

2. An eminence within the prostate gland is called caput gallinaginis, from its fancied resemblance to a woodcock's head.

GA'LLIUM. See *Galium.*

GA'LVANISM. A professor of anatomy, in the university of Bologna, named *Galvani*, was one day making experiments on electricity in his elaboratory: near the machine were some frogs that had been flayed, the limbs of which became convulsed every time a spark was drawn from the apparatus. Galvani, surprised at this phenomenon, made it a subject of investigation, and discovered that metals, applied to the nerves and muscles of these animals, occasioned powerful and sudden contractions, when disposed in a certain manner. He gave the name of animal electricity to this order of new phenomena, from the analogy that he considered existing between these effects and those produced by electricity.

The name animal electricity has been superseded, notwithstanding the great analogy that exists between the effects of electricity and those of Galvanism, in favour of the latter term; which is not only more applicable to the generality of the phenomena, but likewise serves to perpetuate the memory of the discoverer.

In order to give rise to Galvanic effects in animal bodies, it is necessary to establish a communication between two points of one series of nervous and muscular organs. In this manner a circle is formed, one arch of which consists of the animal parts, rendered the subject of experiment, while the other arch is composed of excitatory instruments, which generally consist of several pieces, some placed under the animal parts called supporters, others destined to establish a communication between the latter, are called conductors. To form a complete Galvanic circle, take the thigh of a frog, deprived of its skin; detach the crural nerve, as far as the knee; put it on a piece of zinc; put the muscles of the leg on a piece of silver; then finish the excitatory arch, and complete the Galvanic circle by establishing a communication by means of the two supporters; by means of iron or copper wire, pewter, or lead. The instant that the communicators touch the two supporters, a part of the animal arch formed by the two supporters will be convulsed. Although this disposition of the animal parts, and of Galvanic instruments, be most favourable to the development of the phenomena, yet the composition of the animal and excitatory arch may be much varied. Thus contractions are obtained, by placing the two supporters under the nerve, and leaving the muscle out of the circle, which proves that nerves essentially constitute the animal arch.

It is not necessary for nerves to be entire in order to produce contractions. They take place whether the organs be tied or cut through, provided there exists a simple contiguity between the divided ends. This proves that we cannot strictly conclude what happens in muscular action, from that which takes place in Galvanic phenomena; since, if a nerve be tied or divided, the muscles on which this is distributed lose the power of action.

The cuticle is an obstacle to Galvanic effects; they are always feebly manifested in parts covered by it. When it is moist, fine, and delicate, the effect is not entirely interrupted. Humboldt, after having detached the cuticle from the posterior part of the neck and back, by means of two blisters, applied plates of metal to the bare cutis, and, at the moment of establishing a communication, he experienced sharp prickings, accompanied with a sero-sanguinous discharge.

If a plate of zinc be placed under the tongue, and a flat piece of silver on its superior surface, on making them touch each other, an acerb taste will be perceived, accompanied with a slight trembling.

The excitatory arch may be constructed with three, two, or even one metal only, with alloys, amalgams, or other metallic or mineral combinations, carbonated substances, &c. It is observed that metals which are in general the most powerful excitors, induce contractions so much the more as they have an extent of surface. Metals are all more or less excitants; and it is observed that zinc, gold, silver, pewter, are of the highest rank; then copper, lead, nickel, antimony, &c.

Galvanic susceptibility, like muscular irritability, is exhausted by too long continued exercise, and is recruited by repose. Immersion of nerves and muscles in alkohol and opiate solutions diminishes and even destroys this susceptibility, in the same manner, doubtless, as the immoderate use of these substances in the living man blunts, and induces paralysis in muscular action. Immersion in oxymuriatic acid restores the fatigued parts, to be again acted on by the stimulus. Animals killed by the repeated discharge of an electric battery, acquire an increase of Galvanic susceptibility; and this property subsists unchanged in animals destroyed by submersion in mercury, pure hydrogen gas, azote, and ammonia; and finally, it is totally annihilated in animals suffocated by the vapour of charcoal.

Galvanic susceptibility is extinct in the muscles of animals of warm blood, in proportion as vital heat is dissipated; sometimes even when life is terminated in convulsions, contractility cannot be put into action, although warmth be not completely gone, as though the vital property were consumed by the convulsion, amidst which the animals had expired. In those of cold blood, on the contrary, it is more durable. The thighs of frogs, long after being separated from every thing, and even to the instant of incipient putrefaction, are influenced by Galvanic stimuli; doubtless, because irritability, in these animals, is less intimately connected with respiration, and life more divided among the different organs, which have less occasion to act on each other for the execution of its phenomena. The Galvanic chain does not produce sensible actions (that is, contractions,) until the moment it is completed, by establishing a communication with the parts constituting it. During the time it is complete, that is, throughout the whole space of time that the communication remains established, every thing remains tranquil; nevertheless, Galvanic influence is not suspended: in fact, excitability is evidently increased, or diminished, in muscles that have been long continued in the Galvanic chain, according to the difference of the reciprocal situation of the connecting metals.

If silver has been applied to nerves, and zinc to muscles, the irritability of the latter increases in proportion to the time they have remained in the chain. By this method, the thighs of frogs have been revivified in some degree, and afterwards became sensible to stimuli, that before had ceased to act on them. By distributing the metals in an inverse manner, applying zinc to nerves and silver to muscles, an effect absolutely contrary is observed; and the muscles that possessed the most lively irritability when placed in the chain, seem to be rendered entirely paralytic if they remain long in this situation.

This difference evidently depends on the direction of the Galvanic fluid, determined towards the muscles or nerves, according to the manner in which these metals are disposed, and this is of some importance to be known for the application of Galvanic means to the cure of diseases.

Galvanic Pile.

M. Volta's apparatus is as follows: —

Raise a pile, by placing a plate of zinc, a flat piece of wet card, and a plate of silver, successively; then a second piece of zinc, &c. until the elevation is several feet high; for the effects are greater in proportion to its height; then touch both extremities of the pile, at the same instant, with one piece of iron wire; at the moment of contact, a spark is excited from the extremities of the pile, and luminous points are often perceived at different heights, where the zinc and silver come into mutual contact. The zinc end of this pile appears to be negatively electrified; that formed by the silver, on the contrary, indicates marks of positive electricity.

If we touch both extremities of the pile, after having dipped our hands into water, or, what is better, a saline solution, a commotion, followed by a disagreeable pricking in the fingers and elbow, is felt.

If we place in a tube filled with water, and hermetically closed by two corks, the extremities of two wires of the same metal which are in contact at the other extremity, one with the summit, the other with the base of the pile; these ends, even when separated only by the space of a few lines, experience evident changes at the instant the extremities of the pile are touched; the wire in contact with that part of the pile composed of silver becomes overed with bullæ of hydrogen gas; that which touches the extremity formed by zinc, becomes oxidized, or gives off oxygen gas. Fourcroy attributes this phenomenon to the decomposition of water by the Galvanic fluid, which abandons the oxygen to the metal that touches the positive extremity of the pile; then conducts the other gas invisibly to the end of the other wire, there to be disengaged.

Galvanic Trough.

This is a much more convenient apparatus. Plates of two metals, commonly zinc and copper, are fastened together, and cemented into a wooden trough, so as to form a number of cells; or earthen-ware troughs with partitions being procured, the metals, connected by a slip, are suspended over these, so that in each cell, except at the ends, there is a plate of each metal; then a diluted acid, (usually the sulphuric, nitric, or muriatic, mixed with from twelve to twenty parts of water,) is poured into the trough. It is necessary that the metals be placed in the same order throughout, or one series will counteract another. The zinc end becomes negative, the copper positive; and the power is in proportion to the number of the series; and several such troughs may be connected together, so as to form a most powerful apparatus.

From the numerous experiments of Davy, many new and important facts have been established, and Galvanism has been found one of the most powerful agents in chemistry: by its influence, platina wire has been melted; gold, silver, copper, and most of the metals, have easily been burnt! the fixed alkalies, and many of the earths have been made to appear as consisting of a metallic base, and oxygen; compound substances, which were before extremely difficult to decompose, are now, by the aid of Galvanism, easily resolved into their constituents.

Gama′ndra. See *Stalagmitis.*

Gambie′nse gu′mmi. See *Kino.*

Gamboge. See *Stalagmitis.*

Gambo′gia. See *Cambogia* and *Stalagmitis.*

Gambo′gium. }
Gamboi′dea. } See *Stalagmitis.*

Ga′mma. (From the letter Γ, *gamma*, which it resembles.) A surgical instrument for cauterising a hernia.

Gamphe′le. (From γαμψος, crooked.) The cheek. The jaw.

Ga′ngamon. (From γαγγαμη, a fishing-net, which it was said to resemble.) A name of the omentum. Some call the contexture of nerves about the navel by this name.

GA′NGLION. (γαγγλιον, a knot.) A knot.

1. In anatomy it is applied to a natural knot-like enlargement, in the course of a nerve.

2. In surgery it is an encysted tumour, formed in the sheath of a tendon, and containing a fluid like the white of an egg. It most frequently occurs on the back of the hand or foot.

GA′NGRENE. (γαγγραινα, from γραω, to feed upon.) *Gangrena.* An incipient mortification, so named from its eating away the flesh. Authors have generally distinguished mortification into two stages; the first, or incipient one, they name gangrene, which is attended with a sudden diminution of pain in the place affected; a livid discolouration of the part, which, from being yellowish, becomes of a greenish hue; a detachment of the cuticle, under which a turbid fluid is effused; lastly, the swelling, tension, and hardness, of the previous inflammation subside, and, on touching the part, a crepitus is perceptible, owing to the generation of air in the gangrenous parts.

Such is the state to which the term *gangrene* is applied. When the part has become quite cold, black, fibrous, incapable of moving, and destitute of all feeling, circulation, and life; this is the second stage of mortification, termed *sphacelus.* Gangrene, however, is frequently used synonymously with the word mortification. See *Mortification.*

Ga′rab. An Arabic name for the disorder called *Ægylops.*

GARCI′NIA. (So called in honour of Dr. Garcin, who accurately described it.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria.* Order, *Monogynia.*

Garci′nia mangostana. The systematic name of the mangosteen tree. The mangosteen is a fruit about the size of an orange, which grows in great abundance on the tree called *Garcinia mangostana* by Linnæus, in Java and the Molucca islands. According to the concurring testimonies of all travellers, it is the most exquisitely flavoured, and the most salubrious of all fruits, it being such a delicious mixture of the tart and sweet. The flesh is juicy, white, almost transparent, and of a more delicate and agreeable flavour than the richest grape. It is eaten in almost every disorder, and the dried bark is used medicinally in dysenteries and tenesmus, and a strong decoction of it is much esteemed as a gargle in ulcerated sore throats.

Ga'rgale. (γαργαλη.) *Gargalos. Gargalismos.* Irritation, or stimulation.

Garga'reon. (Hebrew.) The uvula, or glandulous body, which hangs down into the throat.

GA'RGARISM. *Gargarismus.* A wash for the mouth and throat.

GARGARI'SMA. (From γαργαριζω, to gargle.) A gargle.

GARGARI'SMUM. A gargle or wash for the throat.

Ga'rgathum. A bed on which lunatics, &c. were formerly confined.

Gargle. See *Gargarisma.*

Garlic. See *Allium.*

GARNET, Thomas, was born in 1766, at Casterton in Westmoreland. After serving his time to a surgeon and apothecary, he went to study at Edinburgh, where he took his degree at twenty-two, and then attended the London hospitals for two years. In 1790 he settled at Bradford, and began to give private lectures on Philosophy and Chemistry; and here he wrote his Treatise on the Horley Green Spa. But in the following year he removed to Knaresborough, and soon after published an Analysis of the different Waters of Harrowgate, which place he visited during the summer season. About this period he formed the design of going to America; but while waiting to take his passage at Liverpool, he was solicited to deliver some lectures there, which were so favourably received, that he was induced to repeat his course at various other places; and at length the professorship at Anderson's Institution in Glasgow was offered him, where he began lecturing in 1796. Two years after he made a tour to the Highlands, of which he subsequently published an account. On the formation of the Royal Institution in London, he was invited by Count Rumford to become the lecturer there; he accepted the appointment, and the room was crowded with persons of the first distinction and fashion. He then turned his thoughts more seriously to the practice of his profession as likely to afford the most permanent support; but his prospects were cut short by death about the middle of the year 1802. A posthumous volume, entitled "Zoonomia," was published for the benefit of his family.

Garou bark. See *Daphne gnidium.*

Ga'ron. (γαρον.) A kind of pickle prepared of fish; at first it was made from a fish which the Greeks call *Garos;* but the best was made from mackarels. Among the moderns, *garum* signifies the liquor in which fish is pickled.

Garroti'llo. (From *garottar,* to bind closely. Span.) A name of the cynanche maligna, from its sense of strangulation, as if the throat were bound with a cord.

Garrophy'llus. See *Eugenia caryophyllata.*

GAS. (From *gascht,* a German word which means an eruption of wind.) See *Gaz.*

GA'STRIC A'RTERY. *Arteria gastrica.* The right or greater gastric artery, is a branch of the hepatic; the left, or lesser, a branch of the splenic.

GA'STRIC JUICE. *Succus gastricus.* A fluid separated by the capillary exhaling arteries of the stomach, which open upon its internal surface. The œsophagus also affords a small quantity, especially in the inferior part. Modern philosophers have paid great attention to this fluid, and from their several experiments it is known to possess the following properties:—It is the principal agent of digestion, and changes the aliments into a kind of uniform soft paste: it acts on the stomach after the death of the animal. Its effects shew that it is a solvent, but of that peculiar nature that it dissolves animal and vegetable substances uniformly, and without exhibiting a stronger affinity for the one than for the other. Although it is the most powerful agent of digestion in the stomach, its dissolvent power has need of assistance from the action of several secondary causes; as heat, which seems to augment and concentrate itself in the epigastric region; and so long as the exertion of the stomach continues, there is a sort of intestine fermentation, (which should not, however, in its full sense, be compared to the motion by which fermentative and putrescent substances are decomposed); there is also a moderate and peristaltic motion of the muscular fibres of the stomach, which press the aliment on all sides, and perform a slight trituration, while the gastric moisture softens and macerates the food before it is dissolved. By many it has been considered merely as a ferment, but this cannot be the case. See *Digestion.*

It is one of the most powerful antiseptics with which we are acquainted; and, from the experiments of *Spallanzani, Scopoli, Carminati,* and others, its nature appears to be essentially different in the several classes of animals, as they have proved by analysis. The gastric juice of the human subject, when healthy, is inodorous, of a saltish taste, and limpid, like water, unless it be a little tinged with the yellow colour of some bile, that has regurgitated into the stomach. In quantity it is very considerable, as must be evident from the extent of the surface of the stomach, and its continual secretion; but it is most copious when solicited by the stimulus of food. Besides the properties of this fluid before mentioned, it has others which have induced physicians and surgeons to exhibit it medicinally. It cures dyspepsia and intermittent fever. Applied externally, in form of fomentation or poultice, it cures putrid and scrofulous ulcers in a wonderful manner; and it is to be regretted that its utility is not more generally known.

Gastrinum. Potash.

GASTRI'TIS. (From γαςηρ, the stomach.) Inflammation of the stomach. A genus of disease in the class *pyrexiæ*, and order *phlegmasiæ* of Cullen. It is known by pyrexia, anxiety, heat, and pain in the epigastrium, increased when any thing is taken into the stomach, vomiting, hiccup, pulse small and hard, and prostration of strength. There are two species: 1. *Gastritis phlegmonodea*, with acute pain and severe fever. 2. *Gastritis erythematica*, when the pain and fever are slighter, with an erysipelatous redness appearing in the fauces.

Gastritis is produced by acrid substances of various kinds, such as arsenic, corrosive sublimate, &c. taken into the stomach, as likewise by food of an improper nature; by taking large draughts of any cold liquor when the body is much heated by exercise, or dancing; and by repelled exanthemata and gout. Besides these, it may arise from an inflammation of some of the neighbouring parts being communicated to the stomach.

The erysipelatous gastritis arises chiefly towards the close of other diseases, marking the certain approach to dissolution, and being unaccompanied with any marks of general inflammation, or by any burning pain in the stomach.

The symptoms of phlegmonous gastritis, as observed above, are a violent burning pain in the stomach, with great soreness, distention, and flatulency; a severe vomiting, especially after any thing is swallowed, whether it be liquid or solid; most distressing thirst; restlessness, anxiety, and a continual tossing of the body, with great debility, constant watching, and a frequent, hard, and contracted pulse. In some cases, a severe purging attends.

If the disease increases in violence, symptoms of irritation then ensue; there is a great loss of strength, with faintings; a short and interrupted respiration; cold, clammy sweats, hiccups, coldness of the extremities, an intermittent pulse, and the patient is soon cut off.

The event of gastritis is seldom favourable, as the person is usually either suddenly destroyed by the violence of the inflammation, or else it terminates in suppution, ulceration, or gangrene.

If the symptoms are very mild, and proper remedies have been employed at an early period of the disease, it may, however, terminate in resolution, and that in the course of the first, or, at farthest, the second week.

Its termination in suppuration may be known by the symptoms, although moderate, exceeding the continuance of this period, and a remission of pain occurring, whilst a sense of weight and anxiety still remain; and, on the formation of an abscess, cold shiverings ensue, with marked exacerbations in the evening, which are followed by night sweats, and other symptoms of hectic fever; and these at length prove fatal, unless the pus is thrown up by vomiting, and the ulcer heals.

Its tendency to gangrene may be dreaded, from the violence of its symptoms not yielding to proper remedies early in the disease; and, when begun, it may be known by the sudden cessation of the pain; by the pulse continuing its frequency, but becoming weaker, and by delirium, with other marks of increasing debility ensuing.

Fatal cases of this disease shew, on dissection, a considerable redness of the inner coat of the stomach, having a layer of coagulable lymph lining its surface. They likewise shew a partial thickening of the substance of the organ, at the inflamed part, the inflammation seldom extending over the whole of it. Where ulceration has taken place, the ulcers sometimes are found to penetrate through all its coats, and sometimes only through one or two of them.

The cure is to be attempted by copious and repeated bleedings, employed at an early period of the disease, not regarding the smallness of the pulse, as it usually becomes softer and fuller after the operation: also several leeches should be applied to the epigastrium, followed by fomentations, or the hot bath; after which a large blister will be proper. The large intestines may be in some measure evacuated by a laxative clyster; but scarcely any internal medicine can be borne by the stomach, till the violence of the disease is much abated; we may then try magnesia, or other mild cathartic, to clear out the canal effectually. Where acrid substances have been taken, mucilaginous drinks may be freely exhibited, to assist their evacuation and sheath the stomach; otherwise only in small quantity: and, in the former case, according to the nature of the poison, other chemical remedies may come in aid, but ought never to be too much relied upon. Should suppuration occur, little can be done beyond avoiding irritation, and supporting strength by a mild farinaceous diet, and giving opium occasionally to relieve pain.

GASTROCE'LE. (From γαςηρ, the stomach, and κηλη, a tumour.) A hernia of the stomach, occasioned by a protrusion of that viscus through the abdominal parietes.

GASTROCNE'MIUS. (From γαςηρ, the stomach, and κνημη, the leg.) The name of the muscles which form the calf or belly of the leg.

GASTROCNE'MIUS EXTE'RNUS. *Gemellus.* This muscle, which is situated immediately under the integuments at the back part of the leg, is sometimes called *gemellus:* this latter name is adopted by Albinus. Winslow describes it as two muscles, which he calls *gastrocnemii;* and Douglas considers this and the following as a *quadriceps*, or muscle with four heads, to which he gives the name of *extensor tarsi suralis.* It is called *bi femoro calcanien* by Dumas. The gastrocnemius externus arises by two distinct heads. The first, which is the thickest and longest of the two, springs by a strong thick tendon from the upper and back part of the inner condyle of the os femoris, adhering strongly to the capsular ligament of the joint, between which and the tendon is a considerable *bursa mucosa.* The second head arises by a thinner and shorter tendon from the back part of the outer condyle of the os femoris. A little below the joint, their fleshy bellies unite in a middle tendon, and below the middle of the tibia they cease to be fleshy, and terminate in a broad tendon, which, a little above the lower extremity of the tibia, unites with that of the gastrocnemius internus, to form one great round tendon, sometimes called *chorda magna*, but more commonly *tendo Achillis.*

GASTROCNE′MIUS INTE′RNUS. *Tibio peronei calcanien* of Dumas. This, which is situated immediately under the last described muscle, is sometimes named *soleus*, on account of its shape, which resembles that of the sole-fish. It arises by two heads. The first springs by tendinous and fleshy fibres from the posterior part of the head of the fibula, and for some way below it. The second arises from an oblique ridge at the upper and posterior part of the tibia, which affords origin to the inferior edge of the popliteus, continuing to receive fleshy fibres from the inner edge of the tibia for some way down. This muscle, which is narrow at its origin, spreads wider, as it descends, as far as its middle; after which it becomes narrower again, and begins to grow tendinous, but its fleshy fibres do not entirely disappear till it has almost reached the extremity of the tibia, a little above which it unites with the last-described muscle, to form the *tendo Achillis.* This thick round chord is inserted into the lower and posterior part of the os calcis, after sliding over a cartilaginous surface on that bone, to which it is connected by a tendinous sheath that is furnished with a large *bursa mucosa.*

Both the gastrocnemii have the same use, viz. that of extending the foot, by drawing it backwards and downwards.

GASTROCO′LICUS. (From γαστηρ, the stomach, and κωλον, the colon.) A term applied to a vein which proceeds from the stomach to the colon.

GASTRODY′NIA. (From γαστηρ, the stomach, and οδυνη, pain.) Pain in the stomach.

GASTRO-EPIPLOIC ARTERY. *Arteria gastrico-epiploica.* The branch of the greater gastric artery that runs to the epiploon.

GASTRORAPHY. (*Gastroraphe;* from γαστηρ, the stomach, and ραφη, a suture.) The sewing of wounds of the abdomen.

GASTROTO′MIA. (From γαστηρ, the belly, and τεμνω, to cut.) The operation of cutting open the belly and uterus, as in the Cæsarian operation.

GAU′BIUS, JEROME DAVID, a celebrated Dutch physician, was a pupil of the illustrious Boerhaave at Leyden, where he graduated in 1725; and about ten years after he became professor there, and taught with great applause for a period of forty years. His reputation was extended all over Europe by several valuable publications, particularly by his "Institutiones Pathologiæ Medicinalis," and his "Adversaria;" which contributed not a little to the improvement both of the theory and practice of medicine. In another work he treated ably of the medical regulation of the mind: and he printed also a very elegant little book "De Methodo concinnandi formulas Medicamentorum." He died in 1780, in the seventy-sixth year of his age.

Gaule. See *Myrica galé.*

GAZ. (From *Gascht*, German, an eruption of wind.) *Gas.* Elastic fluid. Aëriform fluid. By the word *gaz*, we denote a permanently elastic aëriform fluid, or substance which has the appearance of air; that is to say, it is transparent, elastic, ponderable, invisible, (oxymuriatic acid gas, and a few others excepted,) and not condensible into a liquid or solid state by any degree of cold hitherto known: which distinguishes it from a vapour.

Some of the gases exist in nature without the aid of art, and may therefore be collected; others on the contrary, are only producible by artificial means.

All gases are combinations of certain substances, reduced to the gazeous form by the addition of caloric. It is, therefore, necessary to distinguish in every gas, the matter of heat which acted the part of a solvent, and the substance which forms the basis of the gas.

Gases are not contained in those substances from which we obtain them in the state of gas, but owe their formation to the expansive property of caloric.

Formation of Gases.

The different forms under which bodies appear, depend upon a certain quantity of caloric, chemically combined with them. The very formation of gases corroborates this truth. Their production totally depends upon the combination of the particular substances with caloric; and though called permanently elastic, they are only so because we cannot so far reduce their temperature, as to dispose them to part with it; otherwise they would undoubtedly become fluid or solid.

Water, for instance, is a solid substance in all degrees below 32° of Fahrenheit's scale; above this temperature it combines with caloric, and becomes a fluid. It retains its liquid state under the ordinary pressure of the atmosphere, till its temperature is augmented to 212°. It then combines with a larger portion of caloric, and is converted, *apparently*, into gas, or at least into elastic vapour; in which state it would continue, if the temperature of our atmosphere was above 212°. Gases are therefore solid substances, between the particles of which a repulsion is established by the quantity of caloric.

But as in the gazeous water, or steam, the caloric is retained with but little force, on account of its quitting the water when the vapour is merely exposed to a lower temperature, we do not admit steam amongst the class of gases, or permanently elastic aëriform fluids. In gases, caloric is united by a very forcible affinity, and no diminution of temperature, or increase of pressure, that has ever yet been effected, can separate it from them. Thus the air of our atmosphere, in the most intense cold, or when very strongly compressed, still remains in the aëriform state; and hence is derived the essential character of gases, namely, *that they shall remain aëriform, under all variations of pressure and temperature.*

In the modern nomenclature, the name of every substance existing in the aëriform state, is derived from its supposed solid base; and the term gas is used to denote its existence in this state.

In order to illustrate the formation of gases, or to shew in what manner caloric is combined with them, the following experiment may serve. Put into a retort, capable of holding half a pint of water, two ounces of muriate of soda, (common salt); pour on it half its weight of sulphuric acid, and apply the heat of a lamp; a great quantity of gas is produced, which might be collected and retained over mercury. But to serve the purpose of this experiment, let it pass through a glass receiver, having two openings, into one of which the neck of the retort passes, whilst, from the other, a bent tube proceeds, which ends in a vessel of water. Before closing the apparatus, let a thermometer be included in the receiver, to shew the temperature of the gas. It will be found that the mercury in the thermometer will rise only a few degrees; whereas the water in the vessel which receives the bent tube, will soon become boiling hot.

Explanation.—Common salt consists of muriatic acid, united to soda; on presenting sulphuric acid to this union, a decomposition takes place, especially when assisted by heat. The sulphuric acid unites by virtue of its greater affinity to the soda, and forms sulphate of soda, or Glauber's salt; the muriatic acid becomes therefore disengaged, and takes the gazeous form in which it is capable of existing at the common temperature. To trace the caloric during this experiment, as was our object, we must remark, that it first flows from the lamp to the disengaged muriatic acid, and converts it into gas; but the heat thus expended is chemically united, and therefore not appreciable by the thermometer. The caloric, however, is again evolved, when the muriatic acid gas is condensed by the water, with which it forms liquid muriatic acid.

In this experiment we therefore trace caloric in a chemical combination producing gas; and from this union we again trace it in the condensation of the gas, producing sensible heat.

Such, in general, is the cause of the formation and fixation of gases. It may be further observed, that each of these fluids loses or suffers the disengagement of different quantities of heat, as it becomes more or less solid in its new combination, or as that combination is capable of retaining more or less specific heat.

The discovery of aëriform gazeous fluids has occasioned the necessity of some peculiar instruments, by means of which those substances may be conveniently collected and submitted to examination. The principal ones for that purpose are styled the *pneumatic apparatus.*

The Pneumatic Reservoir, or Cistern,

Is made either of wood or strong sheet-iron, tinned, japanned, or painted. A trough of about two feet long, sixteen inches wide, and fifteen high, has been found to be sufficient for most experiments. Two or three inches below its brim, a horizontal shelf is fastened, in dimension about half or one-third part of the width of the trough. In this shelf are several holes: these holes must be made in the centre of a small excavation, shaped like a funnel, which is formed in the lower part of the shelf.

This trough is filled with water sufficient to cover the shelf to the height of an inch.

The use of this shelf is to support receivers, jars, or bell-glasses, which, being previously filled with water, are placed invertedly, their open end turned down upon the above-mentioned holes, through which the gases, conveyed there and directed by means of the funnel-shaped excavations, rise in the form of air-bubbles into the receiver.

When the gazeous fluids are capable of being absorbed by water, as is the case with some of them, the trough must be filled with mercury. The price and gravity of this fluid make it an object of convenience and economy that the trough should be smaller than when water is used.

A mercurial trough is best cut in marble, free-stone, or a solid block of wood. A trough about twelve inches long, three inches wide, and four deep, is sufficient for all private experiments.

Method of collecting Gases, and transferring them from one vessel to another.

If we are desirous of transmitting air from one vessel to another, it is necessary that the vessel destined to receive it be full of water, or some fluid heavier than air. For that purpose take a wide-mouthed bell-glass, or receiver; plunge it under the water in the trough, in order to fill it; then raise it with the mouth downwards, and place it on the shelf of the trough, so as to cover one or more of the holes in it.

It will now be full of water, and continue so as long as the mouth remains below the surface of the fluid in the cistern; for, in this case, the water is sustained in the vessel by the pressure of the atmosphere, in the same manner as the mercury is sustained in the barometer. It may without difficulty be imagined, that if common air (or any other fluid resembling common air in lightness and elasticity) be suffered to enter the inverted vessel filled with water, it will rise to the upper part, on account of its levity, and the surface of the water will subside. To exemplify this, take a glass, or any other vessel, in that state which is usually called *empty*, and plunge it into the water with its mouth downwards: scarce any of it will enter the glass, because its entrance is opposed by the elasticity of the included air; but if the vessel be turned with its mouth upwards, it immediately fills, and the air rises in bubbles to the surface. Suppose this operation be performed under one of the jars or receivers, which are filled with water, and placed upon the perforated shelf, the air will ascend in bubbles as before, but, instead of escaping, it will be caught in the upper part of the jar, and expel part of the water it contains.

In this manner we see that air may be emptied out of one vessel into another by a kind of inverted pouring, by which means it is made to ascend from the lower to the upper vessel. When the receiving vessel has a narrow neck, the air may be poured, in a similar manner, through an inverted funnel, inserted in its mouth.

If the air is to be transferred from a vessel that is stopped like a bottle, the bottle must be unstopped, with its orifice downwards in the water; and then inclined in such a manner that its neck may come under the perforated excavation of the shelf. The gas will escape from the bottle, and, passing into the vessel destined to receive it, will ascend in it in the form of bubbles.

In whatever manner this operation is performed, the necessity of the excavation in the lower part of the shelf may be readily conceived. It is, as mentioned before, destined to collect the gas which escapes from the vessel, and direct it in its passage towards the vessel adapted to receive it. Without this excavation, the gas, instead of proceeding to the place of its destination, would be dispersed and lost, unless the mouth of the receiving vessel were large.

The vessels, or receivers, for collecting the disengaged gases, should be glass cylinders, jars, or bell-glasses of various sizes; some of them should be open at both ends, others should be fitted with necks at the top, ground perfectly level, in order that they may be stopped by ground flat pieces of metal, glass, slate, &c.; others should be furnished with ground stoppers. Some should be graduated into cubic inches, and sub-divided into decimal or other equi-distant parts. Besides these, common glass-bottles, tumblers, &c. may be used.

Classification of Gases.

All the elastic aëriform fluids with which we are hitherto acquainted, are generally divided, by systematic writers, into two classes; namely, those that are *respirable* and *capable of maintaining combustion*, and those that are *not respirable*, and *incapable of maintaining combustion*. This division, indeed, has its advantage but the term respirable, in its physiological application, has been very differently employed by different writers. Sometimes by the respirability of a gas has been meant its power of supporting life, when repeatedly applied to the blood in the lungs. At other times all gases have been considered respirable which were capable of introduction into the lungs by voluntary efforts, without any relation to their vitality. In the last case, the word respirable seems to us most properly employed, and in this sense it is here used.

Non-respirable gases are those which, when applied to the external organs of respiration, stimulate the muscles of the epiglottis in such a manner as to keep it perfectly close on the glottis; thus preventing the smallest particle of gas from entering into the bronchia, in spite of voluntary exertions.

Of respirable gases, or those which are capable of being taken into the lungs by voluntary efforts, only one has the power of uniformly supporting life, namely, atmospheric air; other gases, when respired, sooner or later impair the health of the human constitution, or perhaps occasion death; but in different modes.

Some gases effect *no positive* change in the blood; animals immersed in it die of a disease produced by the privation of atmospheric air, analogous to that occasioned by their submersion in water.

Others again produce *some positive* change in the blood, as appears from the experiments of Dr. Beddoes and Professor Davy. They seem to render it incapable of supplying the nervous and muscular fibres with principles essential to sensibility and irritability. These gases, therefore, destroy animal life on a different principle.

It is obvious, therefore, that the above classification is not very precise, but capable of misleading the student without proper explanation.

Gaz, azotic. See *Nitrogen.*

Gaz, carbonic acid. This may be obtained by pouring any acid upon carbonate of lime, which thereby becomes decomposed; the effused acid combines with the lime, and forms a new neutral salt, and the carbonic acid is disengaged and escapes in the form of a colourless gaz, viz. carbonic acid gaz. See *Carbonic acid.*

Gaz hepatic. See *Hydrogen gas, sulphuretted.*

Gaz-hydrogen. Inflammable air. See *Hydrogen.*

Gaz, light carbonated hydrogen. See *Carburetted hydrogen gas.*

Gaz, heavy carbonated hydrogen. See *Carburetted hydrogen gas.*

Gazeous oxide of carbon, See *Carbon, gaseous oxide of.*

Geiso'ma. (From γεισον, the eaves of the house.) *Geison.* The prominent parts of the eye-brows, which hang over the eyes like the eaves of a house.

Gei'son. See *Geisoma.*

Gela'sinos. (From γελαω, to laugh.) An epithet for the four middle fore-teeth, because they are shewn in laughter.

Gela'smus. (From γελαω, to laugh.) The Sardonic laugh.

GE'LATINE. Gelly, or jelly. An animal substance soluble in water, but not in alkohol: capable of assuming a well-known elastic or tremulous consistence, by cooling, when the water is not too abundant, and liquifiable again, by increasing its temperature. This last property remarkably distinguishes it from albumen, which becomes consistent by heat. It is precipitated in an insoluble form by tannin, and it is this action of tannin on gelatine that is the foundation of the art of tanning leather.

Jellies are very common in our kitchens; they may be extracted from all the parts of animals, by boiling them in water. Hot water dissolves a large quantity of this substance. Acids likewise dissolve them, as do likewise more particularly the alkalies. Jelly, which has been extracted without long decoction, possesses most of the characters of vegetable mucilage; but it is seldom obtained without a mixture of albumen.

Jellies, in a pure state, have scarcely any smell or remarkable taste. By distillation, they afford an insipid and inodorous phlegm, which easily putrefies. A stronger heat causes them to swell up, become black, and emit a fœtid odour, accompanied with white acrid fumes. An impure volatile alkali, together with empyreumatic oil, then passes over, leaving a spongy coal, not easily burned, and containing common salt and phosphate of lime.

The jelly of various animal substances is prepared for the use of sea-faring persons under the name of portable soup. The whole art of performing this operation consists in boiling the meat, and taking the scum off, as usual, until the soup possesses the requisite flavour. It is then suffered to cool, in order that the fat may be separated. In the next place, it is mixed with five or six whites of eggs, and slightly boiled. This operation serves to clarify the liquid, by the removal of opaque particles, which unite with the white of egg at the time it becomes solid by the heat, and are consequently removed along with it. The liquor is then to be strained through flannel, and evaporated on the water-bath, to the consistence of a very thick paste; after which it is spread, rather thin, upon a smooth stone, then cut into cakes, and, lastly, dried in a stove, until it becomes brittle. These cakes may be kept four or five years, if defended from moisture. When intended to be used, nothing more is required to be done than to dissolve a sufficient quantity in boiling water, which by that means becomes converted into soup.

Gela'tio. (From *gelo*, to freeze.) Freezing; or that rigidity of the body which happens in a catalepsy, as if the person were frozen.

Geme'llus. (From *geminus*, double, having a fellow.) See *Gastrocnemius* and *Gemini.*

GEMINI. *Gemelli* of Winslow. Part of the *marsupialis* of Cowper. *Ischio spini trochanterien* of Dumas. This muscle has been a subject of dispute among anatomists since the days of Vesalius. Some describe it as two distinct muscles, and hence the name it has gotten of *gemini.* Others contend that it ought to be considered as a single muscle. The truth is, that it consists of two portions, which are united together by a tendinous and fleshy membrane, and afford a passage between them to the tendon of the obturator internus, which they inclose as it were in a purse. These two portions are placed under the glutæus maximus, between the ischium and the great trochanter.

The superior portion, which is the shortest and thickest of the two, arises fleshy from the external surface of the spine of the ischium; and the inferior, from the tuberosity of that bone, and likewise from the posterior sacro-ischiatic ligament. They are inserted, tendinous and fleshy, into the cavity at the root of the great trochanter. Between the two portions of this muscle, and the termination of the obturator internus, there is a small *bursa mucosa*, connected to both, and to that part of the capsular ligament of the joint which lies under the gemini.

This muscle assists in rolling the os femoris outwards, and prevents the tendon of the obturator internus from slipping out of its place while that muscle is in action.

Gemu'rsa. (From *gemo*, to groan; so called from the pain it was said to occasion in walking.) The name of an excrescence between the toes.

Genei'as. (From γενυς, the cheek.) The downy hairs which first cover the cheek; also the name of a bandage mentioned by Galen, which covers the cheek, and comes under the chin.

GENERATION. Many ingenious hypotheses have been instituted by physiologists to explain the mystery of generation; but the whole of our knowledge concerning it appears to be built upon the phenomena it affords, and may be seen in the works of Haller, Buffon, Cruickshanks, and Haighton. It is a sexual action, performed in different ways in most animals; many of them have different sexes and require conjunction: such are the human species, quadrupeds, and others. The females of quadrupeds have a matrix, separated into two cavities, *uterus bicornis*, and a considerable number of teats; they have no menstrual flux; most of them bear several young at a time, and the period of their gestation is generally short. The generation of birds is very different. The males have a strong genital organ, which is often double. The vulva in the females is placed behind the anus; the ovaries have no matrices, and there is a duct for the purpose of conveying the egg from the ovarium into the intestines: this passage is called the oviduct. The eggs of pullets have exhibited unexpected facts to physiologists, who examined the phenomena of incubation. The most important discoveries are those of the immortal Haller, who found the chicken perfectly formed, in eggs which were not fecundated. There is no determinate conjunction between fishes; the female deposits her eggs on the sands, over which the male passes, and emits its seminal fluid, doubtless for the purpose of fecundating them; these eggs are hatched after a certain time. The males of several oviparous quadrupeds have a double or forked organ. Insects exhibit all the varieties which are observed in other animals: there are some, indeed the greater number, which have the sexes in two separate individuals; among others, the reproduction is made either with or without conjunction, as in the vine-fretter; one of these insects, confined alone beneath a glass, produces a great number of others. The organ of the male, in insects, is usually armed with two hooks, to seize the female: the place of these organs is greatly varied; with some it as at the upper part of the belly, near the chest, as in the female dragon-fly; in others, it is at the extremity of the *antenna*, as in the male spider. Most worms are hermaphrodite; each individual has both sexes. Polypi, with respect to generation, are singular animals; they are reproduced by buds or offsets: a bud is separated from each vigorous polypus, which is fixed to some neighbouring body, and grows: polypi are likewise found on their surface, in the same manner as branches issue from plants. These are the principal modes of generation in animals. In the human species, which engages our attention more particularly, the phenomena are as follow:—The mode of congress of the man with the woman requires no description; but generation does not consist in that alone: there are certain states or conditions requisite for conception to take place. The ovum must have arrived at a state of maturity. There must be such a determination of blood to the uterus, that, together with the venereal stimulus, shall induce an action in the Fallopian tubes, by which the fimbriæ grasp the ovum that is to be impregnated. During this state of the parts, the semen virile must be propelled into the uterus, in order that its subtle and vivifying portion shall pass along the tube to the ovum. Fecundation having thus taken place, a motion is induced in the vivified ovum, which ruptures the tender vesicle that contains it; the fimbriæ of the Fallopian tube then grasp and convey it into the tube, which, by its peristaltic motion, conducts it into the cavity of the uterus, there to be evolved and brought to maturity, and, at the expiration of nine months, to be sent into the world.

GENERATION, FEMALE ORGANS OF. The parts subservient to generation in a woman are divided into external and internal.

The external parts are the *mons veneris*, the *labia*, the *perinæum*, the *clitoris*, and the *nymphæ*. To these may be added the *meatus urinarius*, or orifice of the urethra. The *hymen* may be esteemed the barrier between the external and internal parts. The internal parts of generation are the *vagina* and *uterus*, and its appendages.

GENERATION, MALE ORGANS OF. The parts which constitute the organs of generation in men are the *penis, testicles*, and *vesiculæ seminales*.

GENIO. (From γενειον, the chin.) Names compounded of this word belong to muscles which are attached to the chin.

GENIO-HYO-GLO'SSUS. (*Musculus genio-hyo-glossus*; from γενειον, the chin *υοειδες*, the os hyoides, and *γλωσσα*, the tongue, so called from its origin and insertion.) *Genio glossus* of some authors. This muscle forms the fourth layer between the lower jaw and os hyoides. It arises from a rough protuberance in the inside of the middle of the lower jaw; its fibres run like a fan, forwards, upwards, and backwards, and are inserted into the tip, middle, and root of the tongue, and base of the os hyoides, near its corner. Its use is to draw the tip of the tongue backwards into the mouth, the middle downwards, and to render its back concave. It also draws its root and the os hyoides forwards, and thrusts the tongue out of the mouth.

GENIO-HYOIDE′US. (*Musculus genio-hyoideus*; from *γενειον*, the chin, and *υοειδες*, the os hyoides; so called from its origin in the chin, and its insertion in the os hyoides.) This muscle constitutes the third layer between the lower jaw and os hyoides. It is a long, thin, and fleshy muscle, arising tendinous from a rough protuberance at the inside of the chin, and growing somewhat broader and thicker as it descends backward to be inserted by very short tendinous fibres into both the edges of the base of the os hyoides. It draws the os hyoides forwards to the chin.

Geniopharynge′us. The constrictor pharyngis superior.

Ge′nipi a′lbum. The plant which bears this name in the pharmacopœias, is the *Artemisia rupestris* of Linnæus; which see.

Ge′nipi ve′rum. The plant directed for medicinal purposes under this title, is the *Achillea; foliis pinnatis, pinnis simplicibus, glabris, punctatis*, of Haller. It has a very grateful smell, and a very bitter taste, and is exhibited in Switzerland in epilepsy, diarrhœa, and debility of the stomach.

GENI′STA. (From *genu*, a knee; so called from the inflection and angularity of its twigs.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*. Order, *Decandria*.

2. The pharmacopœial name of the *Spartium scoparium*; which see.

Geni′sta canarie′nsis. The systematic name of the tree supposed to yield the *Rhodium lignum*: which see.

Geni′sta spino′sa i′ndica. *Bahel schulli.* An Indian tree, a decoction of the roots of which is diuretic. The leaves, boiled and sprinkled in vinegar, have the same effect, according to Ray.

Genita′le. (From *gigno*, to beget.) The privy member.

Genita′lium. (From *genitale*, the membrum virile.) A disease of the genital parts.

Genitu′ra. (From *gigno*.) The male seed. Also the membrum virile.

Ge′non. (From *γονυ*, the knee.) A moveable articulation like that of the knee.

Gensing. See *Ginseng.*

GENTIA′NA. (From *Gentius*, king of Illyria, who first used it.) Gentian.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*. Order, *Digynia*. Gentian.

2. The pharmacopœial name of the gentian root. See *Gentiana lutea*.

Gentia′na a′lba. See *Laserpitium latifolium*.

Gentia′na centau′rium. Lesser centaury was lately so called in the Linnæan system, but now chironia centaurium. See *Chironia centaurium*.

Gentia′na lu′tea. The systematic name of the officinal gentian. *Gentiana rubra.* Felwort. The gentian, that met with in the shops, is the root of the *Gentiana lutea; corollis subquinquefidis rotatis verticillatis, calycibus spathaceis*, of Linnæus; and is imported from Switzerland and Germany. It is the only medicinal part of the plant, has little or no smell, but to the taste manifests great bitterness, on which account it is in general use as a tonic, stomachic, anthelmintic, antiseptic, emmenagogue, and febrifuge. The officinal preparations of this root are the *infusum gentianæ compositum*, and *tinctura gentianæ composita*, of the London Pharmacopœia, and the *infusum amarum, vinum amarum, tinctura amara*, of the Edinburgh Pharmacopœia; and the *extractum gentianæ* is ordered by both.

Gentia′na ru′bra. See *Gentiana.*

GE′NU. The knee.

Genu′gra. (From *γονυ*, the knee, and *αγρα*, a seizure.) A name in Paracelsus for the gout in the knee.

GEOFFRÆ′A. *Geoffroya.* (Named in honour of Dr. Geoffrey.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*. Order, *Decandria*.

2. The pharmacopœial name of the bark of the *Geoffroya inermis foliolis lanceolatis* of Swartz. The plant is a native of Jamaica, where it is distinguished by the name of cabbage-bark tree, or worm-bark tree. It has a mucilaginous and sweetish taste, and a disagreeable smell. According to Dr. Wright of Jamaica, it is powerfully medicinal as an anthelmintic.

Geoffroy′a Jamaice′nsis. The systematic name of the bastard cabbage-tree, or Bulge-water tree. The bark of the *Geoffroya Jamaicensis*, (*inermis foliolis lanceolatis*, of Swartz,) is principally used in Jamaica, and with great success, as a vermifuge.

Geoffroy′a suriname′nsis. The systematic name of a tree, the bark of which is esteemed as an anthelmintic.

GEOFFROY, Stephen Francis, was born at Paris in 1672. After giving him an excellent general education, his father, who was an apothecary, sent him to study his own profession at Montpelier; where he attended the several lectures. On his return to Paris, having already acquired considerable reputation, he was appointed to attend the Duke de Tallard, on his embassy to England, in 1698. Here he was very favourably received, and elected a member of the Royal Society: and he afterwards visited Holland and Italy. His attention was chiefly directed to natural history and the materia medica, his father wishing him to succeed to his establishment at Paris: however he became ambitious of the higher branch of the profession, and at length graduated in 1704. His reputation rapidly increased; and he was called in consultation even by the most distinguished practitioners. In 1709 he was appointed to the professorship of medicine on the death of Tournefort. He then undertook to deliver to his pupils a complete History of the Materia Medica, divided into mineral, vegetable, and animal substances; the first part of which he finished, and about half of the second: this was afterwards published from his papers, in Latin, in three octavo volumes. In 1712 he was made professor of chemistry in the king's garden; and, 14 years after, dean of the faculty. In this office he was led into some active disputes; whence his health, naturally delicate, began to decline; and he died in the beginning of 1731. Notwithstanding his illness, however, he completed a work, which had been deemed necessary by preceding deans, but never accomplished; namely, a Pharmacopœia, which was published under the name of "Code Medicamentaire de la Faculté de Paris."

Gera′nis. (From γερανος, a crane; so called from its supposed resemblance to an extended crane.) A bandage for a fractured clavicle.

GERA′NIUM. (From γερανος, a crane; so called because its pistil is long like the bill of a crane.) Class, *Monadelphia*. Order, *Decandria*. The name of a genus of plants in the Linnæan system. Geranium, or cranes-bill.

Gera′nium batrachioi′des. See *Geranium pratense.*

Gera′nium columbi′num. Doves foot. See *Geranium rotundifolium.*

Gera′nium moscha′tum. The adstringent property of this plant has induced practitioners to exhibit it in cases of debility and profluvia.

Gera′nium prate′nse. The systematic name of the crow-foot cranes-bill. *Geranium batrachioides.* This is the *Geranium pratense* of Linnæus; it possesses adstringent virtues, but in a slight degree.

Gera′nium robertia′num. Stinking cranes-bill. Herb robert. This common plant has been much esteemed as an external application in erysipelatous inflammations, cancer, mastodynia, and old ulcers, but is now deservedly fallen into disuse.

Gera′nium rotundifo′lium. The systematic name of the doves-foot. *Geranium columbinum.* This plant is slightly astringent.

Gera′nium sanguina′rium. See *Geranium sanguineum.*

Gera′nium sangui′neum. The systematic name of the *Geranium sanguinarium.* Bloody cranes-bill. *Geranium sanguineum* of Linnæus. The adstringent virtues ascribed to this plant do not appear to be considerable.

Germander. See *Teucrium chamædrys.*

Germander, water. See *Teucrium Scordium.*

Geroco′mia. (From γερων, an aged person, and κομεω, to be concerned about.) That part of medicine which regards the regimen and treatment of old age.

Gerontopo′gon. (From γερων, an old man, and πωγων, a beard; so called because its downy seed, while enclosed in the calyx, resembles the beard of an aged man.) The herb old man's beard. Purple-flowered tragopogon.

Geronto′xon. (From γερων, an old person, and τοξον, a dart.) A small ulcer, like the head of a dart, appearing sometimes in the cornea of old persons. The socket of a tooth.

Geropo′gon. See *Gerontopogon.*

Ge′ryon. Quicksilver.

GESNER, Conrad, was born at Zurich in 1516. His father was killed in the civil war, and left him in such poverty, that he was obliged to become a servant at Strasburg. His master allowed him to devote some time to study, in which he made great progress; and having acquired a little money, he went to Paris, where he improved rapidly in the classics and rhetoric, and then turned his attention to philosophy and medicine. But he was soon compelled to return to his native country, and teach the languages, &c. for a livelihood. This enabled him afterwards to resume his medical studies at Montpelier, and he graduated at Basil in 1540. He then settled in his native city, where he was appointed professor of philosophy, which office he discharged with great reputation for 24 years. He had an early predilection for botany, which led him to cultivate other parts of natural history; he was the first collector of a museum, and acquired the character of being the greatest naturalist since Aristotle. He also founded and supported a botanic garden, had numerous drawings and wooden engravings made of plants, and appears to have meditated a general work on that subject. He likewise discovered the only true principles of botanical arrangement in the flower and fruit. Though of a feeble and sickly constitution, he traversed the Alps, and even sometimes plunged into the waters in search of plants: he also carefully studied their medical properties, and frequently hazarded his life by experiments on himself; indeed he was at one time reported to have been killed by the root of doronicum. His other occupations prevented his entering very extensively into practice, but his enlarged views rendered him successful; and the profits of his profession enabled him to support the great expense of his favourite pursuits. He gave also many proofs of liberal and active friendship. He died of the plague in 1565. His chief works are his "Historiæ Animalium," in three folio volumes, with wooden cuts; and a pharmacopœia, entitled "De Secretis Remediis Thesaurus," which passed through many editions.

GE'UM. 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria.* Order, *Polygynia.*

2. The pharmacopœial name of the two following species of this genus.

Ge'um rivale. The root is the part directed for medicinal uses. It is inodorous, and imparts an austere taste. In America it is in high estimation in the cure of intermittents, and is said to be more efficacious than the Peruvian bark. Diarrhœas and hæmorrhages are also stopped by its exhibition.

Ge'um urba'num. The systematic name of the herb bennet, or avens. *Caryophyllata. Herba benedicta. Caryophyllus vulgaris. Garyophilla. Janamunda.* The root of this plant, *Geum urbanum; floribus erectis, fructibus globosis villosis, aristis uncinatis nudis, foliis lyratis,* of Linnæus, has been employed as a gentle styptic, corroborant, and stomachic. It has a mildly austere, somewhat aromatic taste, and a very pleasant smell, of the clove kind. It is also esteemed on the continent as a febrifuge.

Giddiness. See *Vertigo.*

Gilead, balsam. See *Amyris gileadensis.*

GILBERT, William, was born at Colchester in 1540. After studying at Cambridge, he went abroad for improvement, and graduated at some foreign university. He returned with a high character for philosophical and chemical knowledge, and was admitted into the college of physicians in London, where he settled about the year 1573. He was so successful in his practice, that he was at length made first physician to Queen Elizabeth, who allowed him a pension to prosecute philosophical experiments. He died in 1603, leaving his books, apparatus, and minerals to the college of physicians. His capital work on the magnet was published three years before his death; it is not only the earliest complete system on that subject, but also one of the first specimens of philosophy founded upon experiments; which method the great Lord Bacon afterwards so strenuously recommended.

Gill-go-by-ground. See *Glecoma hederacea.*

Gilliflower. See *Dianthus caryophyllus.*

GIN. Geneva. Hollands. The names of a spirit distilled from malt or rye, which afterwards undergoes the same process, a second time, with juniper-berries. This is the original and most wholesome state of the spirit; but it is now prepared without juniper-berries, and is distilled from turpentine, which gives it something of a similar flavour. The consumption of this article, especially in the metropolis, is immense, and the consequences are, as Dr. Willan observes, pernicious to the health of the inhabitants.

Ginger. See *Zingiber.*

Gi'ngiber. See *Zingiber.*

Gingibra'chium. (From *gingivæ,* the gums, and *brachium,* the arm.) A name for the scurvy, because the gums, arms, and legs, are affected with it.

Gingi'dium. A species of *Daucus.*

Gi'ngihil. See *Zingiber.*

Gingipe'dium. (From *gingivæ,* the gums, and *pes,* the foot.) A name for the scurvy, because the gums, arms, and legs are affected.

GINGI'VÆ. (From *gigno,* to beget, because the teeth are, as it were, born in them.) The gums. See *Gums.*

GI'NGLYMUS. (*γιγγλυμος,* a hinge.) The hinge-like joint. A species of diarthrosis or moveable connection of bones, which admits of flexion and extension, as the knee-joint, &c.

GI'NSENG. (*Ginseng,* Indian.) See *Panax quinquefolium.*

Ginseng root. See *Panax quinquefolium.*

Gir. Quick-lime.

Gi'rmir. Tartar.

Gizzard. The gizzards or stomachs of poultry, with white flesh, have long been considered, in France, as medicinal. They have been recommended in obstructions of the urinary passages, complaints of the bladder, and nephritic pains; but particularly as a febrifuge. Bouillon Lagrange considers its principal substance as oxygenated gelatine, with a small quantity of extractive matter.

Glabe'lla. (From *glaber,* smooth; because it is without hair.) The space betwixt the eyebrows.

GLADI'OLUS. (Dim. of *gladius,* a sword; so named from the sword-like shape of its leaf.) The name of a genus of plants in the Linnæan system. Class, *Triandria.* Order, *Monogynia.*

Gladi'olus lu'teus. See *Iris pseudacorus.*

Gla'ma. (*γλαμα.*) The sordes of the eye.

GLAND. (*Glandula;* diminutive of *glans,* a gland.) A gland is an organic part of the body, composed of blood-vessels, nerves, and absorbents, and destined for the secretion or alteration of some peculiar fluid. The glands of the human body are divided, by anatomists, into different classes, either according to their structure, or the fluid they contain. According to their fabric, they are distinguished into four classes:

1. Simple glands.

2. Compounds of simple glands.
3. Conglobate glands.
4. Conglomerate glands.

According to their fluid contents, they are more properly divided into, 1. Mucous glands. 2. Sebaceous glands. 3. Lymphatic glands. 4. Salival glands. 5. Lachrymal glands.

Simple glands are small hollow follicles, covered with a peculiar membrane, and having a proper excretory duct, through which they evacuate the liquor contained in their cavity. Such are the mucous glands of the nose, tongue, fauces, trachea, stomach, intestines and urinary bladder, the sebaceous glands about the anus, and those of the ear. These simple glands are either dispersed here and there, or are contiguous to one another, forming a heap in such a manner that they are not covered by a common membrane, but each hath its own excretory duct, which is never joined to the excretory duct of another gland. The former are termed solitary simple glands, the latter aggregate or congregate simple glands.

The compound glands consist of many simple glands, the excretory ducts of which are joined in one common excretory duct; as the sebaceous glands of the face, lips, palate, and various parts of the skin, especially about the pubes.

Conglobate, or, as they are also called, lymphatic glands, are those into which lymphatic vessels enter, and from which they go out again: as the mesenteric, lumbar, &c. They have no excretory duct, but are composed of a texture of lymphatic vessels connected together by cellular membrane—they are the largest in the fœtus.

Conglomerate glands are composed of a congeries of many simple glands, the excretory ducts of which open into one common trunk: as the parotid gland, thyroid gland, pancreas, and all the salival glands. Conglomerate glands differ but little from the compound glands, yet they are composed of more simple glands than the compound.

The excretory duct of a gland is the duct through which the fluid of the gland is excreted. The vessels and nerves of glands always come from the neighbouring parts, and the arteries appear to possess a high degree of irritability. The use of the glands is to separate a peculiar liquor, or to change it. The use of the conglobate glands is unknown.

GLANDORP, Matthias Louis, was born at Cologne in 1595. Soon after commencing his medical pursuits, he went to Padua, which had at that time great reputation. He improved so much in anatomy under Spigelius, that he was deemed competent to give public demonstrations: and he took his degree in 1618. He settled in Bremen, whence his family originated; and he was so successful in practice, that he was raised to the most honourable offices. He was physician to the Archbishop and to the Republic, when he died in 1640. He left several works, with plates, containing many important observations on anatomy, &c. The principal are his "Speculum Chirurgorum," and a Treatise on Issues and Setons. He was very partial to the use of the actual cautery, even in the most common disorders.

GLA′NDULA LACHRYMA′LIS. See *Lachrymal gland.*

Gla′ndulæ myrtifo′rmes. See *Carunculæ myrtiformes.*

GLA′NDULÆ PACCHIO′NIÆ. (From *Pacchioni,* the name of the discoverer.) A number of small, oval, fatty substances, not yet ascertained to be glandular, situated under the dura mater, about the sides of the longitudinal sinus. Their use is not known.

Glandulosoca′rneus. An epithet given by Ruysch to some excrescences, which he observed in the bladder.

GLANS. A gland, or nut.

GLANS PE′NIS. The very vascular body that forms the apex of the penis. The posterior circle is termed the *corona glandis.* See *Corpus spongiosum urethræ.*

Gla′ns unguenta′ria. See *Guilandina moringa.*

GLASS. This substance is sometimes employed by surgeons, when roughly powdered, to destroy opacities of the cornea.

Glass of antimony. A vitreous sulphuretted oxide of antimony.

Glass wort, snail-seeded. See *Salsola kali.*

Gla′stum. (*Quasi callastum; from Callia,* who first used it.) The herb woad.

Glauber's salt. See *Sodæ sulphas.*

Glau′cium. (From γλαυκος, blue, or yellow; so called from its colour.) The yellow-horned poppy.

GLAUCO′MA. (From γλαυκος, blue; because of the eye becoming of a blue, or sea-green colour.) *Glaucosis.* An opacity of the vitreous humour. It is difficult to ascertain, and is only to be known by a very attentive examination of the eye.

Glauco′sis. See *Glaucoma.*

GLECO′MA. (From γληχων, the name of a plant in Dioscorides.) Class, *Didynamia.* Order, *Gymnospermia.* The name of a genus of plants in the Linnæan system. Ground ivy.

Gleco′ma hedera′cea. The systematic name of the ground ivy or gill. *Hedera terrestris. Glecoma hederacea; foliis reniformibus crenatis,* of Linnæus. This indigenous plant has a peculiar strong smell, and a bitterish somewhat aromatic taste. It is one of those plants which was formerly much esteemed for possessing virtues that, in the present age, cannot be detected. In obstinate coughs it is a favourite remedy with the poor.

Gle′chon. (From γληχων.) Pennyroyal.

Glechoni′tes. (From γληχων, pennyroyal.) Wine impregnated with pennyroyal.

GLEET. In consequence of the repeated attacks of gonorrhæa, and the debility of the part occasioned thereby, it not unfrequently happens, that a gleet, or constant small discharge takes place, or remains behind, after all danger of infection is removed. Mr. Hunter remarks, that it differs from gonorrhæa in being *uninfectious*, and in the discharge consisting of globular particles, contained in a slimy mucus, instead of serum. It is unattended with pain, scalding in making of water, &c.

GLE′NE. (γληνη.) Strictly signifies the cavity or socket of the eye; but by some anatomists is also used for that cavity of a bone which receives another within it.

GLE′NOID. (*Glenoides*; from γληνη, a cavity, and ειδος, resemblance.) The name of some articulate cavities of bones.

Gleu′cinum. (From γλευκος, must.) An ointment, in the preparation of which was must.

Gleu′xis. (From γλυκυς, sweet.) A sweet wine.

Gli′scere. To increase gradually, properly as fire does; but, by physical writers, is sometimes applied to the natural heat and increase of spirits; and by others to the exacerbation of fevers, which return periodically.

Gliscra′sma. (From γλισχραινω, to become glutinous.) Lentor. Viscidity.

Glischro′cholos. (From γλισχρος, viscid, and χολη, the bile.) An epithet for bilious viscid excrements.

Glisoma′rgo. White chalk.

GLISSON, Francis, was born in Dorsetshire, 1597. He studied at both the English universities; but took his degree of doctor in Cambridge, where he was made regius professor of Physic, which office he held about forty years. He settled however to practise in London, and became a Fellow of the College in 1635; four years after which he was chosen reader of Anatomy, and distinguished himself much by his lectures "De Morbis Partium," which he was requested to publish. During the civil wars he retired to Colchester, where he practised with great credit; and was there during the siege of that town by the Parliamentary forces. He was one of the members of the society, which, about the year 1645, held weekly meetings in London to promote Natural Philosophy; and which having removed to Oxford during the troubles, was augmented after the Restoration, and became ultimately the present Royal Society. He was afterwards several years president of the College of Physicians, and died at the advanced age of eighty. He left the following valuable works, 1. A Treatise on the Rickets. 2. The Anatomy of the Liver, which he described much more accurately than any one before, and particularly the capsule of the Vena Portarum, which has since been named after him. 3. A large metaphysical treatise "De Natura Substantiæ Energetica," after the manner of Aristotle. 4. A Treatise on the Stomach, Intestines, &c. a well arranged and comprehensive work, with various new observations, which came out the year before his death.

Glisson's Capsule. See *Capsule of Glisson.*

Globate gland. See *Gland.*

GLOBULA′RIA. (From *globus*, a globe; so called from the shape of its flower.) The French daisy.

Globula′ria a′lypum. The leaves of this plant are used in some parts of Spain in the cure of the venereal disease. It is said to act also as a powerful but safe cathartic.

GLO′BUS HYSTE′RICUS. The air rising in the œsophagus, and prevented by spasm from reaching the mouth, is so called by authors, because it mostly attends hysteria, and gives the sensation of a ball ascending in the throat.

Glo′mer. (A clue of thread.) Mostly applied to glands.

Glomerate gland. A gland formed of a glomer of sanguineous vessels, having no cavity, but furnished with an excretory duct; as the lachrymal and mammary glands.

Glossa′gra. (From γλωσσα, the tongue, and αγρα, a seizure.) A rheumatic pain in the tongue.

GLO′SSO. (From γλωσσα, the tongue.) Names compounded with this word belong to muscles, nerves, or vessels, from their being attached, or going to the tongue.

Glosso-pharynge′al nerves. The ninth pair of nerves. They arise from the processes of the cerebellum, which run to the medulla spinalis, and terminate by numerous branches in the muscles of the tongue and pharynx.

Glosso-pharynge′us. (*Musculus glossopharyngeus*; from γλωσσα, the tongue, and φαρυγξ, the pharynx: so named from its origin in the tongue, and its insertion in the pharynx.) See *Constrictor pharyngeus superior.*

Glo′sso-staphyli′nus. (*Musculus glossostaphylinus*; from γλωσσα, the tongue, and ϛαφυλη, the uvula; so named because it is fixed in the tongue, and terminates at the uvula.) See *Constrictor isthmi faucium.*

Glossoca′tochos. (From γλωσσα, tongue, and κατεχω, to hold.) An instrument in P. Ægineta for depressing the tongue. A spatula linguæ. The antient glossocatochus was a sort of forceps, one of the blades of which served to depress the tongue, while the other was applied under the chin.

GLOSSOCE'LE. (From γλωσσα, the tongue, and κηλη, a tumour.) An extrusion of the tongue.

Glossocoma. A retraction of the tongue.

Glossocomi'on. (From γλωσσα, a tongue, and κομεω, to guard.) By this was formerly meant a case for the tongue, for a hautboy; but the old surgeons, by metaphor, use it to signify an instrument, or case, for containing a fractured limb.

Glo'tta. (γλωττα, the tongue.) The tongue.

GLUCINE. For the discovery of this earth we are indebted to Vauquelin, who found it, in 1795, in the Aigue-marine or beryl, a transparent stone, of a green colour, and in the emerald of Peru. It exists combined with silex, alumine, lime, and oxid of iron in the one; and with the same earths, and oxid of chrome, in the other. It has lately been discovered in the gadolinite by Mr. Ekeberg.

Its name is taken from the Greek word (γλυκυς) which signifies sweet or saccharine, because it gives that taste to the salts it forms.

Glucine is white, light, and soft to the touch. It is insipid, and adheres to the tongue; and is infusible by itself in the fire. Its specific gravity is 2.967. It is soluble in alcalies and their carbonates, and in all the acids except the carbonic and phosphoric, and forms with them saccharine and slightly astringent salts. It is exceedingly soluble in sulphuric acid used to excess. It is fusible with borax, and forms with it a transparent glass. It absorbs one-fourth of its weight of carbonic acid. It decomposes sulphate of alumine. It is not precipitated by the hydro-sulphurets nor by prussiate of potash, but by all the succinates. Its affinity for the acids is intermediate between magnesia and alumine.

To obtain this earth, reduce some beryl to an impalpable powder, fuse it with three times its weight of potash, and dissolve the mass in muriatic acid. Separate the silex by evaporation and filtration, and decompose the remaining fluid by adding carbonate of potash; re-dissolve the deposit when washed in sulphuric acid, and by mingling this solution with sulphate of potash, alum will be obtained, which crystallizes.

Then mix the fluid with a solution of carbonate of ammonia, which must be used in excess; filter and boil it, and a white powder will gradually fall down, which is glucine.

GLO'TTIS. (From γλωττα, the tongue.) The superior opening of the larynx at the bottom of the tongue.

GLUTEAL ARTERY. A branch of the internal iliac artery.

GLU'TEN. (*Quasi geluten; from gelo, to congeal.*) Glue, Lentor. See *Gluten, animal and vegetable.*

GLU'TEN ANIMAL. This substance constitutes the basis of the fibres of all the solid parts. It resembles in its properties the gluten of vegetables.

GLU'TEN, VE'GETABLE. If wheat flour be made into a paste, and washed in a large quantity of water, it is separated into three distinct substances; a *mucilaginous saccharine matter*, which is readily dissolved in the liquor, and may be separated from it by evaporation; *starch*, which is suspended in the fluid, and subsides to the bottom by repose; and *gluten*, which remains in the hand, and is tenacious, very ductile, somewhat elastic, and of a brown gray colour. This glutinous substance is obtained from several vegetables in great abundance, and, when dried, becomes a horny mass. It is insoluble both in water and spirit of wine, and, if boiled with the former, it coagulates like the white of an egg. It burns like horn, and affords the same products by distillation in the dry way. It readily putrifies when kept in a cold and moist place.

GLUTE'US MA'XIMUS. (From γλουτος, the buttocks.) *Gluteus magnus* of Albinus. *Glutæus major* of Cowper, and *Ilio sacro femoral* of Dumas. This broad radiated muscle, which is divided into a number of strong fasciculi, is covered by a pretty thick aponeurosis derived from the *fascia lata*, and is situated immediately under the integuments. It arises fleshy from the outer lip of somewhat more than the posterior half of the spine of the ilium, from the ligaments that cover the two posterior spinous processes; from the posterior sacro-ischiatic ligament; and from the outer sides of the os sacrum and os coccygis. From these origins the fibres of the muscle run towards the great trochanter of the os femoris, where they form a broad and thick tendon, between which and the trochanter there is a considerable *bursa mucosa*. This tendon is inserted into the upper part of the *linea aspera*, for the space of two or three inches downwards; and sends off fibres to the fascia lata, and to the upper extremity of the vastus externus. This muscle serves to extend the thigh, by pulling it directly backwards; at the same time it draws it a little outwards, and thus assists in its rotatory motion. Its origin from the coccyx seems to prevent that bone from being forced too far backwards.

GLUTE'US ME'DIUS. *Ilio trochanterien* of Dumas. The posterior half of this muscle is covered by the gluteus maximus, which it greatly resembles in shape; but the anterior and upper part of it is covered only by the integuments, and by a tendinous membrane which belongs to the fascia lata. It arises fleshy from the outer lip of the anterior part of the spine of the ilium, from part of the posterior surface of that bone, and likewise from the fascia that covers it. From these origins its fibres run towards the great trochanter, into the outer and posterior part of which it is inserted by a broad tendon. Between this tendon and the trochanter there is a small thin *bursa mucosa*. The uses of this muscle are nearly the same as those of the gluteus maximus; but it is not confined, like that muscle, to rolling the os femoris outwards, its anterior portion being capable of turning that bone a little inwards. As it has no origin from the coccyx, it can have no effect on that bone.
